The practical result of the investigation on the part of the municipality has been the reception of a large number of orders for installations from municipalities and private persons throughout Italy and applications for particulars from other countries. Mr. Neilson informs me that the system is now being investigated by the Pasteur Institute of Paris. It may be seen in full working order in many houses in Florence and there is no doubt that the statement that evil odours are abolished and that the effluent is colourless as well as odourless is absolutely true. I have inspected the effluent on a good many occasions. I have found it slightly milky at first owing to the living infusorians present but it becomes perfectly clear after standing a few days when the infusorians have perished. It has a faint smell of truffles at first. One installation has been in action now for three years and is said to have required no attention whatever and to be absolutely satisfactory.

The most important point to elucidate is—What influences bring about these results and how do they work? As I have said already it is difficult to obtain precise information on this subject. I have, however, been shown under the microscope by Mr. Neilson specimens taken from the cesspools and, as far as I can make out, the work is done by one variety of anaerobic bacterium, which he cultivates specially, and by several varieties of infusorians, which are, of course, aerobic. I have not seen the anaerobic bacterium but Mr. Neilson informs me that it works at the bottom of the cesspool upon solid excrement, breaking it up and rising to the upper regions of the cesspool with the disintegrated particles. Here these bacteria form food for some of the infusorians which in their eager endeavours to devour the bacteria further break up the particles of solid matter. Under a magnifying power of 200 diameters I have had two brief glimpses at the infusorians and observed at least five varieties. They all seem to eat voraciously and are all free-swimming and marvellously active. Their movements vary, some darting rapidly, some vibrating, some twisting, and some rotating. The larger varieties are distinctly ciliated and my impression is that they all belong either to the ciliata or flagellata. A very definite mouth is present in the larger varieties. Mr. Neilson states that one variety eats the solid matter, two varieties destroy the anaerobic life, another one feeds on the matter which is in process of liquefaction, and a fifth eats incessantly apparently whatever it comes in contact with, including bacteria, cocci, &c., and takes a large share in the clearing of the liquid. I gather from the inventor also that these infusorians split up the gases and that the ultimate gases formed are carbonic acid gas and marsh gas "and others which have a smell like truffles." He is very emphatic in stating that these animalcula can live only when the gases are allowed to escape. He informs me that the lowest temperature at which the system has hitherto been found to work successfully is 4° C and that the highest hitherto tried is 38° C. It will be understood that a system with the pretensions of this one will find its greatest application in countries where cesspools are used for sewage disposal, but Mr. Neilson states that he is fully prepared to apply it on a large scale to the water drainage of cities and asserts further that his system will displace others on account of its efficiency, cheapness, comparative rapidity, and automatic action. It will be observed that he places no reliance whatever upon the bacteria which are ordinarily found in sewage; he says that he has no use for them. This and the use of infusorians characterise the system and mark it off from other systems of bacterial sewage purification I can obtain no absolute proof of the destruction of disease germs under the process.

Mr. Neilson himself confesses that he is an amateur at the subject but has devoted six years entirely to its investigation. I understand that the inventor's attention was first directed to the subject by observations upon the life found in pools into which the house drainage of his villa near Siena ran. One cannot fail to be impressed by Mr. Neilson's enthusiasm for his subject and by the successful results which are evident on an inspection of one of his cesspools in working order. The naked-eye superiority of Mr. Neilson's effluent placed side by side with specimens from Sutton and Exeter is striking. Even if all the statements made do not prove on further investigation to be entirely correct, nevertheless every dweller in the cesspool-riddled cities of the continent will have reason to be grateful if the system is more generally applied. Indeed, in Florence already many of us are thankful for the removal of offensive odours from spots which we frequent or from the neighbourhood of our dwellings, and it is a further satisfaction to know that the municipality has approached Mr. Neilson with a view to the application of his method to that eyesore of the city, the system of urinals.

Florence.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE CENTENARY PROGRAMME.

THE following and final programme, celebrating the Centenary, has now been arranged by the council of the society with the help of the Centenary Committee. The information has been published in our columns already in detail but our readers may wish to see the complete arrangements as a whole.

Monday, May 22nd, "Centenary Day."—At 5 o'clock P.M. the President will receive the Honorary Fellows and Fellows at the Society's House, 20, Hanover-square, W. Light refreshments will be provided from 4.30 P.M. onwards.

At 5.15 the President will deliver a short congratulatory address. After the address he will admit the new Honorary Fellows and present them with their diplomas.

The Centenary Banquet will be held at the Hotel Cecil at 8 P.M., but Fellows and guests are requested to be seated in their places punctually at 7.45 in order to be ready to receive His Royal Highness the Prince of Wales.

At 7.45 the Prince of Wales will sign the roll of the society, be admitted an Honorary Fellow, and receive his diploma.

Tuesday, May 23rd.—At 8.30 P.M. Dr. Henry Head, F.R.S. (Marshall Hall prizeman), will deliver a special address on the Afferent Nerves under a New Aspect. The conclusions expressed in the address will be drawn from investigations carried out in conjunction with Dr. W. H. R. Rivers and Mr. James Sherren. After the address there will be an informal reception by the President and council.

Wednesday, May 24th.—There will be a conversazione in the Natural History Museum, Cromwell-road. A reception will be held by Sir R. Douglas Powell, P.R.C.P. Lond., the President of the Society, and Lady Powell from 9.30 P.M. to 10.30 P.M.

An arrangement has been made with the District Railway Company by which on this evening the subway connecting the South Kensington station with the grounds of the museum will be open for the use of guests.

A small, but it is hoped an interesting, exhibition will be arranged in the society's rooms for the inspection of Fellows and others from Monday, May 22nd, to Thursday, May 25th inclusive, between the hours of 11 A.M. and 6.30 P.M. each day.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XII.[1]

THE POOR-LAW AND MEDICAL SERVICE (*Continued*).

The Poor-law Medical Service in Ireland.—Death of Mr. William Smyth of Dungloe.—The Grievances of the Dispensary Service.—The Absolutely Necessary Reforms.

THE condition of the Poor-law medical service in Ireland has for many years been a scandalous blot on the administration of the country. Politicians, journalists, and enlightened general opinion have condemned the system; the medical press has called loudly and persistently for its improvement; the Irish Medical Association more than four years ago published a statement of studied moderation every word of which showed the necessity for immediate reform; the leaders of medical opinion in Ireland, in the medical schools of Dublin, Belfast, Galway, and Cork have advised their pupils not to take office in the service—advice which has not been neglected; and the Local Government Board of Ireland, under whose jurisdiction the dispensary districts lie, has admitted the necessity of ameliorating existing conditions. But nothing has been done that really counts when the magnitude of the evil is realised.

In the same way as the case of Mr. J. Lamont serves to illustrate by one lurid story the troubles of the Scottish Poor-law medical officer, so the infinitely sadder event of Mr. William Smyth's heroic death may be regarded as a supreme example of the trials of the Poor-law medical officer in Ireland. Here the sacrifice of a noble life proved terribly dramatically and finally that the Poor-law medical service in Ireland must be reformed. Mr. Smyth's death is too recent to need more than the briefest record for all its tragedy to recur to our mind. He was dispensary medical officer of Dungloe No. 2 District, co. Donegal, and died on Nov. 22nd, 1901, from an attack of typhus fever contracted in his efforts to fight that disease which had broken out in part of his district, the island of Arranmore on the western seaboard of Donegal. Mr. Smyth was most anxious to remove his patients to the isolation hospital at Glenties on the mainland but met with such difficulties and opposition that Dr. B. McCarthy, Local Government Board inspector, was sent to his assistance. As the fishermen would neither lend their boats nor row the fever patients across, an old and unseaworthy boat was purchased by the relieving officer and the two medical men, who were novices at rowing, set off for the island. Here fresh difficulties arose, as the friends of the patients opposed all removal which was only accomplished by the aid of the police. On the homeward journey the medical men hailed a boat which was manned by six policemen and asked to be taken in tow to Burton Port, but these men refused to render any assistance, fearing infection. Tired out with their unaccustomed exertions the two intrepid rowers reached Burton Port at last where an ambulance awaited their arrival and the patients were removed to Glenties. Mr. Smyth caught typhus fever and died in a few days, a veritable martyr to his splendid sense of duty.

This narrative epitomises the position of the Poor-law medical officer in Ireland. Here we have a man left single-handed amid a frightened, ignorant, callous peasantry, to combat a dangerously infectious disease as best he could. The sea must be passed before he can reach the hovels of the sick; he has no skilled assistance and no lay assistance. The representative of the department under which he works gives strenuous help at the last, but the dispensary medical officer dies at his post. And he dies for no purpose, for if similar circumstances arose to-day there is no guarantee against similar issues.

The manifest and manifold grievances of the medical officers of the Poor-law or public dispensary service in Ireland have been set forth frequently and clearly. In the columns of the *Journal of the Irish Medical Association*,[2] the *Medical Press and Circular*, and THE LANCET full particulars will be found of all the abuses under which the luckless officer of the Dispensary Medical Service abides. But no purview of the medical profession in its public relations can be complete which does not deal with the matter in detail, however often it may have been dealt with before, for the dispensary medical officers are the Poor-law officers, sanitary officers, and general practitioners of Ireland, and a large proportion of the Irish population comes into contact with no other medical men. Few people in England understand the hardships under which the Poor-law medical officers work in Scotland or Ireland and some may even be content to believe that the attitude of the bureaucracy, which stigmatises the officers of both services as chronic malcontents, is justifiable.

The main grievances of the medical officers of the Poor-law system in Ireland are the hardship of their work, the scantiness of their pay, the absence of promotion, the difficulty of obtaining holidays, the absence of definite arrangement for superannuation pensions, and their anomalous position as servants of the Poor-law guardians. They can be conveniently considered in the order in which I have set them down.

The following are the duties appointed for the dispensary medical officer by the Irish Local Government Board in respect of the dispensary work. He must attend the dispensaries on such days and hours as the Local Government Board may direct and afford outdoor medical relief to all poor persons presenting the "black ticket" for dispensary treatment. He must attend the patient's residence when he receives a "red ticket" and treat the case to its fortunate or unfortunate issue. He must keep a register of all patients attended either at their homes or at the dispensary and send the book monthly for inspection by the guardians, and he must also give a certificate, if needed, of the state of health of any dispensary patient if called upon to do so by the guardians. He [illegible] and make quar[illegible] Board for new su[illegible] his own medicine, for the last annual report of the Local Government Board of Ireland shows that in 746 dispensary districts only 47 compounders or dispensers are kept. He must send samples out of each consignment of drugs to be tested, he must pack up and return all empties. He must report to the guardians monthly his hours of attendance and the duration of his stay at the dispensaries. He must send quarterly to the Local Government Board and to the board of guardians a statement showing the number of tickets issued, the number of tickets cancelled, and the number of lunatics certified, as well as the number of cases that have occurred of small-pox, typhus fever, diphtheria, typhoid fever, and scarlet fever. He must answer questions about dispensary arrangements and anything else that either authority may want to know.

The tickets alluded to as "red" or "black" are in the gift of the guardians and are issued by them personally or through their relieving officers or wardens to the sick poor. The black ticket entitles its holder to medical advice and medicine at the dispensary; the red ticket is an order to the medical officer to visit the patient at his home. The guardians are supposed to be the sole judges of who is "poor," but the wardens, as the official ticket issuers are called, can distribute the tickets as they like, and they frequently abuse the discretion vested in them. This does not signify so much in the matter of the black ticket as the medical officer has to attend at the dispensary at certain hours and it does not make much difference to him when he is there if some of the patients to whom he has to administer charitable relief can really pay for his services. Every such abuse of the system diminishes the medical man's chance of making money out of private practice, but in many districts of Ireland this chance is so slight that the luckless medical men see [illegible] But the n[illegible] red ticket is an [illegible] it as a peremptory order, to visit the sick at their own homes. These homes may lie widely apart from each other and from the medical officer's house, journeys in cars over vile roads or in boats over rough seas may be necessitated, so that anything like an abuse of the issue of red tickets leads to most serious consequences. The medical man's time is occupied in long and unremunerative travel and his shallow purse is drained by boat- and cart-hire. But these things do not prevent the wrongful issue and employment of red tickets, while unfortunately it is not easy to say in Ireland who is and who is not entitled to the benefits of rate-paid medical attention.

[2] See especially an admirable "Report on the Poor-law Medical System in Ireland, with special reference to the Dispensary Medical Service" by the Special Commissioner of the British Medical Journal—British Medical Journal, March 26th, 1904.

So much for the dispensary officer's duties as a dispensary officer pure and simple, and they would seem to account for much of his time. The dispensary medical officer is, however, medical officer of health for his district also, and the whole sanitary administration of rural Ireland, such as it is, is in his hands. The larger cities, Dublin, Belfast, Londonderry, Limerick, and Cork, for example, have a proper medical officer of health, but there is no provision of county medical officers as obtains in Scotland. The dispensary medical officer is the only person in the countryside with an elementary knowledge of sanitation, but he is powerless to do anything. His additional salary as health officer amounts to only some £20, his time is over-occupied with his dispensary duties, he may have a few private patients to whom he must give a certain amount of attention, while he must feel that any efforts which he makes towards improving matters will be largely wasted. The people will not understand his object and the majority of his uneducated masters, the guardians, will share their ignorance. The dispensary medical officer is also the public vaccinator, factory surgeon, and very usually the registrar for births, deaths, and marriages. For these appointments he receives small fees which he is glad to earn. He also attends the men of the Royal Irish Constabulary Force and the coastguard and lighthouse staff. Such is a brief enumeration of the work performed by the dispensary medical officer.

The average pay is a fraction above £100 per annum as dispensary medical officer. To this pittance has to be added from £10 to £25 received for the discharge of sanitary duties but with this addition we find that out of 810 dispensary medical officers 500 receive less than £150 per annum, only 2 receive more than £200, and 32 receive under £100. Fees of 2*s.* 6*d.*, 2*s.*, 1*s.*, and 6*d.*, as registrar, vaccination officer, certifying factory surgeon, and surgeon to the Royal Constabulary and the coastguard and lighthouse staff have also to be added, and like the English guardians the Irish guardians point to vaccination fees as an excuse for starvation salaries. In the dispensary service there is virtually no promotion, so that a man cannot comfort himself for taking a small salary while he is young with a feeling that as he grows older and the expenses of a family begin to fall upon him his income will increase to meet his needs. Nor is there any certainty of a pension. It is within the discretion of the board of guardians to grant a pension to a retiring dispensary officer but they can refuse it to anyone who has offended them. Then the unfortunate medical man, who cannot be expected to have made any great provision for old age out of his income, must toil on in harness until he dies, being forced by penury to continue the work, however unfit to do his duties.

Tables I. and II. show the superannuation allowances, some of them terminable at a certain date, of all medical dispensary officers and workhouse medical officers paid during the year ending March 31st, 1903, which I have extracted from the figures in the last report of the Local Government Board of Ireland. The age, period of service in years, and salary are also given.

These figures, taken as a whole, form an unanswerable indictment of the system. We have only to look at the long average length of service and the low average size of pension to come to this conclusion. I have placed an asterisk (*) against a few special cases. It will be seen that out of 82 hard-working men 13, or nearly one-sixth, were compelled to remain in harness until over 70 years of age, one working until his eighty-fourth year. The Local Government Board of Ireland acknowledges that this position exists but seems unable to bring itself to take the initiative in promoting any remedy. No one should be placed in circumstances like those of the Irish dispensary medical officer and be compelled to abide in them until old age overtakes him, because he has been unable to make provision for the end of life and has no certainty of obtaining a pension. Note the case of the dispensary medical officer numbered in the first table "63" who was for 45 years in the service and who, when verging on 80 years of age receives a pension of a little more than

30*s.* per week. From one such text a sermon of complete indictment of the whole system could be preached. Note, also, the number of retirements at an unusually early age. The cause assigned to most of these retirements is physical breakdown. The exacting nature of the life of the Irish dispensary medical officer could not be shown in a more lurid way, and a factor in producing this frequent breakdown is the monotonous persistency of the work. There is no definite regulation providing for any recreation or holiday leave for the medical officers. Until recently the medical officer got no holiday at all. The guardians refused to make any grant towards the expenses or the fees of a substitute, and the medical officer never had money enough to pay a substitute and also to go away. And so to the manifest detriment of his own interests and those of the community whom he served, he remained day in and day out on his dreary rounds. The position has been improved by a general order made in 1899 by the Local Government Board of Ireland for an annual vacation not exceeding four weeks for each medical officer, while three years later recoupment was provided from the Board of one half of the amount paid by the guardians with the Local Government Board's sanction. It will be seen that the unfortunate medical officer has to get the acquiescence of the guardians, who in their turn have to get the sanction of the Local Government Board. There ought not to be any necessity for all this routine. In every walk of life it is now recognised that a hard-working employé has a right to a holiday, that he ought to be allowed to go as a matter of right in enjoyment of his salary, and ought not to be taxed by having to pay a substitute. The fact that many, a majority, of the officers of the Irish Medical Poor-law Service do now get these fitting opportunities for a vacation shows that the local authorities who control the service are waking up to the situation. Soon the officer's right to a holiday will be taken by him as a right, at present it is yielded to him after requests, and perhaps bickering, as a concession.

And over and above all these grievances there is the medical position to be remembered. Always the razor is used to cut the firewood. The scientific man is never spared, if the guardians or the Local Government Board of Ireland can help it, by a proper supply of assistants to take the lower administrative details off his hands. Imagine 746 dispensary districts with but 47 compounders, and 119 dispensary assistants among them, so that the great majority of the dispensary medical officers have to dispense their own medicine. Again, there is a dearth of midwives who might act as assistants to the medical officers and spare them much arduous waiting and watching, for 551 women do not go far when it is remembered how much of the country the poor relief system of Ireland has to serve. The unpacking of medicines, the despatching of samples, and the returning of empties, clearly the work of a boy or porter at a few shillings a week, have to be done in most cases by the medical officer himself Then his clerical work has to be considered. He has to keep records of his work to be shown to the guardians, he has to supply statistics for the consideration of the Local Government Board, and no amount of overwork is allowed to excuse a default.

knows it. There
sh ore assistance, the
du ers by central and
local authority should be less vexatiously in evidence, the elections of the medical officers should be managed on proper principles, and the Local Government Board should support the medical officers where the local authorities try to oppress them. Everyone knows the crying need of these things but nothing is done.

(*To be continued.*)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on May 13th, Mr. John Tweedy, the President, being in the chair.

Mr. Herbert J. Paterson was introduced and the President handed to him a cheque for the amount of the Jacksonian prize, together with a document declaratory of the award.

It was resolved that diplomas of Membership should be issued to 108 successful candidates.

A report was circulated, which had been drawn up by Dr. P. H. Pye-Smith, chairman of the Laboratories Committee, on the history and work of the Laboratories since their opening in 1890. The report was received and entered on the minutes and the best thanks of the Council were given to Dr. Pye-Smith for his interesting and valuable account.

The President reported that the solicitor of the College had made inquiries regarding the person calling himself wrongfully F.R C.S. and stated that he had instructed the solicitor to take steps with a view to prosecuting this person for his false assumption of the title F.R.C.S.—The proceedings of the President were approved and confirmed.

The Council resolved to give a reception at the College to the members and visitors of the Atlantic Union on a date to be settled later.

The Council elected a Fellows Dinner committee.

A letter was read from the registrar of University College, Sheffield, stating that in the Charter for incorporating a University of Sheffield which the Privy Council has recommended His Majesty the King to grant, provision has been made for the Royal College of Surgeons of England to have a representative on the University Court and asking that steps may be taken for the appointment of such a representative. The Council appointed the President as their representative.

The President reported that he had received a letter from Mr. Thomas Bryant presenting to the College some letters and a photograph of historic interest.—The best thanks of the Council were given to Mr. Bryant for his gift.

The President reported that he had approved of a proposal by the executors of the late Mrs. Jane Begley to purchase £800 2½ per cent. Consols in the name of the Royal College in satisfaction of Mrs. Begley's bequest to the College.—The President and the Vice-Presidents were requested to draw up regulations for the award of the Begley scholarship.

The Council resolved—

study from the date of passing the preliminary science examination.

ASYLUM REPORTS.

City of London Asylum (*Annual Report for 1904*).—During the year under review there were admitted into this asylum 178 patients; the discharges amounted to 142, of whom 57 had recovered, and the deaths to 34. Only one of the deaths was due to pulmonary tuberculosis, a very satisfactory record. The resident population at the close of 1904 was 565, 257 being private patients. The visiting committee reports the resignation of the medical superintendent, Dr. Ernest W. White, who retires upon a liberal pension, and expresses its high appreciation of his services. He is succeeded by Dr. R. H. Steen. The private department continues to be an important feature of this asylum; a table is given showing its steady growth since its initiation in 1892. During 1904 86 private patients were received. The profits arising from the maintenance of this class allow of the transfer of a considerable surplus in relief of the county rate. According to the printed regulations the charge for the maintenance of private patients is £1 1*s.* weekly but the Commissioners in Lunacy in their report state that the charge is from one to two guineas. In either case the charge is a moderate one and should meet a genuine need. The charge for the home patients is given as 12*s.* 3*d.* per week, which is high in comparison with the average of public asylum charges. Dr. White's report makes mention of a case of suicide by hanging by means of a rope attached to a gas pipe. The general health of the asylum was good. Only one case of typhoid fever occurred, whereas in previous years there had been outbreaks of typhoid fever and colitis which were due to contamination of the asylum well and disappeared on changing the water-supply. The Commissioners comment on the fact that at this asylum the practice of allowing patients to go out on trial, which has worked advantageously in most asylums, has never been adopted and they commend its adoption. Their report speaks favourably of the condition of the institution throughout.

St. Andrew's Hospital for Mental Diseases at Northampton for the Middle and Upper Classes (*Report for 1904*).—From the report of Mr. J. Bayley, the medical superintendent, it appears that this hospital received in the year 98 cases, of which 20 were readmissions; the discharges amounted to 64 and the deaths to 16. The average number resident was 405. The percentage of deaths on these was 3·95. The percentage of recoveries on admissions, excluding transfers, was 30·26. In this institution the patients pay for their own maintenance, but it appears from the report of the committee of management that 88 patients were assisted in their payments, presumably by the institution from its funds, to the extent of some £3700 in the year. In this way their payments were made up to the lowest rates ordinarily charged. This hospital has the advantage of a seaside house where patients can be sent on leave.

THE ROYAL SOCIETY CONVERSAZIONE.

"AN evening with the microscope" might fairly describe the conversazione held in the rooms of the Royal Society on May 17th. The subjects under microscopic study varied considerably in kind and comprised histology, bacteriology, marine biology, and the microscopic inspection of metallic surfaces. The exhibit of Professor J. B. Farmer, F.R.S., Mr. J. E. S. Moore, and Mr. C. E. Walker in the principal library attracted a good deal of attention. As the readers of THE LANCET might anticipate, this exhibit referred to the cellular constituents peculiar to cancerous and reproductive tissues. The structures known as "Plimmer's bodies" have been regarded as parasitic organisms or as specific cellular peculiarities confined to malignant tissues. They have recently been identified as being present also in normal reproductive tissues in which they form a definite organ of the cell during its conversion to a spermatozoon and the two preceding divisions. Close by this exhibit Dr. H. Charlton Bastian, F.R.S., illustrated the simplest kind of protoplasm. Common bacteria are found to grow freely in a solution of ammonium tartrate, from which it is evident that they must fashion their protoplasm in some way from carbon, hydrogen, oxygen, and nitrogen only, though sulphur and phosphorus (which are completely absent in this case) are commonly regarded as necessary constituents of living matter. Brevet Lieutenant-Colonel W. B. Leishman, R.A.M.C., showed the parasite of "kala-azar," a protozoal organism found in the spleen and other organs in cases of "kala-azar," an extremely fatal disease occurring in epidemic form in Assam and also in endemic form in other parts of India and the tropics. The mode of infection is not known. In artificial cultures the parasite developes into a flagellated organism closely resembling a trypanosome. Mr. H. S. Wilson, M.B., illustrated the isolation of bacillus typhosus from water by means of alum precipitation. The precipitate, which is known to be destructive to many water and sewage organisms, is without action on the typhoid bacillus. Mr. D. Findlayson exhibited a very interesting accessory to the microscope which is designed to enable the images of two different objects mounted on separate microscopic slides to be projected side by side into the field of view, thereby enabling a thorough comparison to be made of their respective points of difference and resemblance. The "comparascope," as it is called, will be obviously valuable in bacteriological work and in the detection of adulteration of starches and other substances. Mr. Carl Zeiss exhibited an optical appliance to facilitate visual perception of ultra-microscopic particles. Particles it is stated of far less than half a wave-length can be made visible. The application of the electric current to the production of high temperature was very well illustrated in certain exhibits. The Director of the National Physical Laboratory, for example, exhibited furnaces constructed of rare earths (zirconia, &c.) such as are used in the Nernst electric lamp. The furnaces are available for temperatures ranging between 800° and 2000° C. The apparatus has been used for the determination of the melting point of platinum and a model in working order was exhibited. Mr. R. S. Hutton exhibited some new models of laboratory electric furnaces. The exhibit included samples of refractory oxides fused in the electric furnace and a number of quartz tubes. Mr. R. H. Lock showed a very interesting series of specimens of cross-bred maize illustrating inheritance. The resulting cobs showed strikingly different degrees of blending of character illustrated by the differently coloured grains.

Perhaps the most popular exhibit was that of Sir William Crookes, F.R.S., who showed some very interesting specimens illustrating the action of light and of radium upon glass. Radium will produce in a few days as intense a colouration in glass containing manganese as exposure to the sun has taken years to effect. The exhibit included specimens of glass taken from greenhouses at Kew Gardens. In these instances the glass adopted had a greenish tint but by the action of sunlight the glass had become colourless, while in other cases a purple tint had developed owing to the manganese oxide present. Close by this exhibit Mr. G. W. Beilby demonstrated in a very pretty experiment the phosphorescence caused by the beta-rays of radium. Dealing with a similar subject Sir William Ramsay, F.R.S., illustrated the action of actinium or emanium emanation on a sensitive screen. The substance is obtained from pitchblende and when the emanation impinges on a sensitive screen the screen becomes luminous. The luminous patch can be "blown away" but reappears. The demonstration given by Sir Oliver Lodge in the meeting room of the use of electric valves for the production of high tension continuous current was very interesting. These valves can be employed to accumulate electricity supplied from an intermittent or jerky source and to store it at a steady high potential. Thus a small portable coil may be used to imitate some of the effects of a much larger coil by the storage and accumulation of impulses. Among the applications suggested are the separation of metallic fumes and the dissipation of fog.

The company present was a very large one and of the usual representative and distinguished character, and was received by Sir William Huggins, K.C.B., O.M., D.C.L., the president.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 19, 1827.

CARLISLE, in his first letter to Mr. PEEL,[1] says, "If, however, the greediness of a few individuals should expose this subject (man-midwifery) to free discussion, and the judgment of married men and modest women should be copiously awakened, perhaps the general custom of employing women may be again resorted to;" and in his second letter,[2] this disgusting egotist submits the following proposition:—"I, therefore, now propose the restoration of the practice of midwifery to females, beginning with the introduction of the *wives, widows, or female kindred of medical practitioners*." Hence, according to his own showing, he recommends that the wives, widows, and female kindred of medical men should addict themselves to "a *degrading vocation*," a "dishonourable vocation;" that they be "associated with nurses and gossips for whole days and nights," * * * * * * "in a lying-in room, where often none but ignorant women are present."

---

[1] Vide "Looking Back" in THE LANCET of March 4th, 1905, p. 592.

[2] Letter in *The Times* of May 1st, 1827, copied into THE LANCET of May 5th, 1827.

If the GENERAL PRACTITIONERS of the British empire, previously to the publication of this proposal, were ignorant of the opinion entertained of them by the *Hospital Surgeons* of London, they cannot be so now. Sir Anthony confesses, indeed, that he has not written "*unadvisedly*," which implies, we presume, that his letters have been sanctioned by his colleagues with "enlarged intellect." One would have supposed that Carlisle could have communicated his "professional thoughts" to Mr. Peel without mixing them up with charges of the most horrible description and suggestions of the most insulting character, appertaining to the professional avocations of GENERAL PRACTITIONERS and their wives. Pray who are the wives of general practitioners? Who? why, the daughters of the most respectable, the most wealthy, and independent gentlemen and merchants of England; ladies who, in no single circumstance, are inferior to the "wives, widows, and female relatives," of the ignorant, conceited, malignant, lying, insulting, boasting, hospital surgeons of this metropolis. If Carlisle had made it the chief object of his life to accomplish the degradation of general practitioners, he could not more completely execute his task than in the adoption of his proposal. The wife, quoth this benighted oyster, "may thus secure his female patients against the inroads of his competitors, and establish a respectable maintenance for such females;" so that we are to believe, first, that the talents of the general practitioner are not a sufficient security against the inroads of competitors; and, secondly, that he is incapable of procuring for his wife those comforts which, from her station in society, she requires; two inferences so truly insulting to the feelings of this class of gentlemen, that it is with pain we commit them to paper, although for the purpose of exposure and refutation. In this country, and we are delighted that it should be so, it is considered that nothing bespeaks want of talent, want of energy, want of industry, want of a correct and honourable spirit, more decidedly, than for a man to require from his wife the execution of any portion of labour as a necessary adjunct to his support, and we believe this feeling pervades even the inferior grades of tradesmen; what, amongst such people, [illegible] proachful than to say of a ma [illegible] half supports, his family; yet [illegible] would Carlisle reduce the general practitioner! and thus render him a bankrupt in character, as well as in pocket, whilst his wife and female relatives would be excluded from all respectable society, through following a "degrading and dishonourable vocation." Oh that there were

> ———"In every honest hand a whip,
> To lash the rascal naked through the world."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

[illegible] was 9133 births and 4486 [illegible] week ending May 13th. [illegible] se towns, which had been 15·6, 16·5, and 15·4 per 1000 in the three preceding weeks, further declined last week to 15·0 per 1000. In London the death-rate was 14·7 per 1000, while it averaged 15·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 4·0 in Burton-on-Trent, 5·9 in Leyton, 7·4 in Hornsey, 7·6 in Handsworth (Staffs.), 8·3 in Willesden, 9·0 in Aston Manor and in Stockton-on-Tees, and 9·9 in Walthamstow; the highest rates were 20·8 in Oldham, 20·9 in Great Yarmouth, 21·2 in Sheffield, 21·9 in Merthyr Tydfil, 23·5 in Wigan, and 23·7 in Warrington. The 4486 deaths in these towns last week included 401 which were referred to the principal infectious diseases, against 453, 460, and 469 in the three preceding weeks; of these 401 deaths, 174 resulted from measles, 110 from whooping cough, 37 from diarrhœa, 31 from scarlet fever, 27 from diphtheria, and 22 from "fever" (principally enteric), but not any from small-pox. In Hornsey, Norwich, Plymouth, Walsall, Rochdale, Burnley, Huddersfield, and eight other smaller towns no death from any of the principal infectious diseases was registered; the highest death-rates from these diseases were recorded in Hanley, West Bromwich, Smethwick, Warrington, Oldham, Sheffield, Middlesbrough, West Hartlepool, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in West Bromwich, Smethwick, Coventry, Warrington, Sheffield, Middlesbrough, West Hartlepool, and Merthyr Tydfil; from diphtheria in West Hartlepool; from whooping-cough in West Ham, Hanley, Smethwick, Preston, and Middlesbrough; from "fever" in South Shields; and from diarrhœa in Wolverhampton. The mortality from scarlet fever showed no marked excess in any of the large towns. No death from small-pox was registered either in London or in any of the 75 large provincial towns. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals, which had been 17, 16, and 17 at the end of the three preceding weeks, was again 17 at the end of last week; two new cases were admitted during the week, against six, four, and four in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2177, against 2128, 2182, and 2152 at the end of the three preceding weeks; 319 new cases were admitted during the week, against 253, 255, and 235 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 272, 306, and 256 in the three preceding weeks, further declined last week to 251, but were 20 above the number in the corresponding period of last year. The causes of 49, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Leeds, Hull, Newcastle-on-Tyne, and in 53 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Coventry, Leicester, Liverpool, Manchester, Blackburn, Bradford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·8, 18·8, and 18·0 per 1000 in the three preceding weeks, rose again to 19·5 per 1000 during the week ending May 13th and was 4·5 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·2 in Leith and 15·2 in Perth to 21·1 in Glasgow and 22·1 in Aberdeen. The 653 deaths in these towns last week included 32 which were referred to measles, 30 to whooping-cough, nine to diarrhœa, six to diphtheria, four to "fever," and two to scarlet fever. In all 83 deaths resulted from these principal infectious diseases last week, against 69, 59, and 57 in the three preceding weeks. These 83 deaths were equal to an annual rate of 2·5 per 1000, which was 1·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 23, 21, and 16 in the three preceding weeks, rose again last week to 32, of which 26 occurred in Glasgow and five in Edinburgh. The deaths from whooping-cough, which had been 23, 27, and 26 in the three preceding weeks, increased again to 30 last week, and included 20 in Glasgow, four in Edinburgh, two in Aberdeen, and two in Paisley. The fatal cases of diarrhœa, which had been 12, eight, and 15 in the preceding weeks, further declined last week to nine, of which four were registered in Glasgow, two in Edinburgh, and two in Aberdeen. The deaths from diphtheria, which had been six, one, and four in the three preceding weeks, rose again to six last week and included three in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been three, one, and three in the three preceding weeks, further rose to four last week and included one case of typhus in Glasgow and one case of plague belonging to Leith. The two deaths from scarlet fever were both recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 126, 121, and 132 in the three preceding weeks, declined again last week to 108, but were 18 in excess of the number in the corresponding period of last year. The causes of 20, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·4, 21 9, and 22·0 per 1000 in the three preceding weeks, rose to 23·7 per 1000 during the week ending May 13th. During the past four weeks the death-rate has averaged 22·8 per 1000, the rates during the same period being 15·0 in London and

17·7 in Edinburgh. The 172 deaths of persons belonging to Dublin registered during the week under notice were 12 in excess of the number in the preceding week, and included eight which were referred to the principal infectious diseases, against 12, eight, and eight in the three preceding weeks; of these, four resulted from measles, three from diarrhœa, and one from "fever," but not any from small-pox, scarlet fever, diphtheria, or whooping-cough. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·2 in London and 2·3 in Edinburgh. The fatal cases of measles, which had been four, two, and three in the three preceding weeks, rose last week to four. The deaths from diarrhœa, which had been three, three, and one in the three preceding weeks, increased again to three last week. The 172 deaths in Dublin last week included 25 of children under one year of age and 55 of persons aged 60 years and upwards; the deaths of infants were slightly below the number in the preceding week, but those of elderly persons showed a considerable excess. Four inquest cases and four deaths from violence were registered; and 72, or more than two-fifths, of the deaths occurred in public institutions. The causes of three, or nearly 2 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: T. W. Myles and C. M. Woods to the *Glory*, for disposal; W. H. Pope to the *Donegal;* E. G. E. O'Leary to the *Sapphire II.;* D. H. Vickery to the *Dryad;* F. J. Gowans to the *Leda;* H. Woods to the *Circe;* E. B. Kenny to the *Hebe;* and J. Shipsey to the *Speedwell.*

ROYAL ARMY MEDICAL CORPS.

According to the May Army Orders amendments are to be made in the King's Regulations in regard to the examination of Majors, R.A.M.C. The following is to be inserted at the end of paragraph 1197:—

> Failure in one technical subject will necessitate re-examination in that subject alone; failure in more than one technical subject will entail re-examination in all (to take effect from Jan. 1st, 1906).

The following will be substituted from Jan. 1st, 1906, for Paragraphs 3 and 4 of Appendix VIII.B:—

> Technical subjects: 3. Sanitation of towns, camps, transports, and all places likely to be occupied by troops in peace or war; epidemiology and management of epidemics. 4. The laws and customs of war so far as they relate to the care of the sick and wounded.

Paragragh 5 (*c*) is cancelled. The following addition will be made to the list of "books recommended:" "The Laws and Customs of War on Land," edited by Professor T. E. Holland, K.C.

Major G. S. Mansfield has embarked for service in Bermuda. Major J. D. Alexander is appointed to the charge of the Military Hospital, Birr, vice Major H. St. G. S. Hore, who proceeds to Dublin for duty. Major A. A. Sutton, D.S.O., is appointed Senior Medical Officer, Sierra Leone. Colonel R. H. Quill is promoted to Surgeon-General and appointed Principal Medical Officer at Netley. Lieutenant-Colonel O. E. P. Lloyd, V.C., is promoted to Colonel and appointed Administrative Medical Officer at Dover.

Major C. H. Burtchaell, from the Seconded List, to be Major (dated May 3rd, 1905). Lieutenant-Colonel A. H. Burlton retires on retired pay (dated May 17th, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major R. Chalmers to be Surgeon-Lieutenant-Colonel (dated May 2nd, 1905). Surgeon-Lieutenant W. J. Reid to be Surgeon-Captain (dated April 30th, 1905).

THE SIR WILLIAM TAYLOR PRIZE, 1904.

The Sir William Taylor prize of 25 guineas has been awarded to Major W. H. Horrocks, R.A.M.C., in recognition of his distinguished practical and scientific work in connexion with his article on Drain Flushing as contributed to the *Royal Army Medical Corps Journal* in March, 1904, and for his work on the Saprophytic Existence of the Micrococcus Melitensis outside the Body, its Mode of Entrance into the Animal Body and Mode of Leaving the Same, as published in the reports of the Commission for the Investigation of Mediterranean Fever appointed under the supervision of an advisory committee of the Royal Society.

IMPROVED PAY IN THE INDIAN MEDICAL SERVICE.

Certain improvements in the pay of the Indian Medical Service, as specified below, have recently received the sanction of the Secretary of State for India in Council. 1. In the case of military appointments carrying consolidated rates of pay, increases in those rates have been made analogous to the increases in the pay of rank sanctioned in 1903. This does not apply to appointments held by officers in the rank of colonel or surgeon-general, as no increase was made in the pay of those ranks. 2. The pay of the majority of civil appointments has been increased, the increases in this case also being analogous to the recent increases in the pay of rank. The changes that will affect the largest number of officers are as follows: (*a*) The pay of civil and agency surgeons, first and second class, is fixed at Rs.50 a month more, and Rs.50 a month less, respectively, than the pay drawn by officers of the same rank in charge of native regiments. (*b*) Officers in charge of first- and second-class central jails will receive Rs.100 and Rs.50 respectively more than is drawn by officers of the same rank in charge of native regiments. The following new rates may also be mentioned: (*a*) Inspector-General of Civil Hospitals, Bengal, Rs.2500; (*b*) Inspector-General of Civil Hospitals, Punjab and Burma, Rs.2250; and (*c*) Sanitary Commissioners, Rs.1500-60-1800. 3. The military rates of leave pay are revised as follows:—

On first appointment	£250	a year.
After the commencement of the tenth year's service for pension	300	,,
After the commencement of the fifteenth year's service for pension	450	,,
After the commencement of the twentieth year's service for pension	600	,,
After the commencement of the twenty-fifth year's service for pension	700	,,

4. The promotion of officers from captain to major is accelerated by six months in the case of officers who fulfil certain specified conditions. 5. The rates of half-pay have been assimilated to those drawn by officers of the Royal Army Medical Corps—viz.:—

Under five years' service	6*s.* 0*d*	a day.
After five ,, ,, ...	8*s.* 0*d.*	,,
,, 10 ,, ,, ...	10*s.* 0*d.*	,,
,, 15 ,, ,, ...	13*s.* 6*d.*	,,

THE NEW MILITARY HOSPITAL AND SCHOOL AT MILLBANK.

It has been announced that under a new scheme about to be introduced the War Office authorities will provide their own specially qualified medical officers and hope thereby to reduce the expenditure on the medical department and to increase its efficiency. This scheme includes the erection of an army medical school at Millbank on a vacant site in close connexion with the newly constructed military hospital there, the building of which has been completed and will shortly be opened. The new Army Medical College will, it is estimated, cost £250,000.

VITAL STATISTICS OF THE FRENCH ARMY FOR THE YEAR 1902.

The vital statistics of the French army for 1902, compiled under the direction of Professor G. H. Lemoine of Val-de-Grâce, have recently been issued from the National Printing Office. In this volume of close on 500 pages, with numerous charts and diagrams, there is to be found, says a writer in the *Archives de Médecine et de Pharmacie Militaires* for last February, not merely a bald compilation of figures but a detailed and authoritative analysis of the varied morbid causes which have exerted an influence on the sanitary condition of the troops. The general sick-rate for the year was 594 per 1000 of strength against 615 per 1000 in 1901. Cases treated in the "infirmaries" are included in this rate as well as those which are admitted into the regular hospitals. The chief sources of disability were as follows, per 1000 of strength: affections of the respiratory organs, 65·8; sore-throat, 57·9; influenza, 25·3; mumps, 17·1; articular rheumatism, 17·0; measles, 12·0; tuberculosis, 7·3; and typhoid fever, 3·8. In Algeria paludal affections head the list with 70·3 per 1000 admissions, while the rate for typhoid fever rises to 17 8 per 1000, or nearly five times that of the home army. The diagram that shows the mortality-rate is a striking one. In 1880 the death-rate for the home army was 9·46 per 1000, but ever since it has gone down steadily till in 1902 it was no more than 4·24 per 1000. Including the troops that are stationed in Algeria the general death-rate for the year 1881 was 11·98 per 1000, but by 1901 it had gone down to 5·37 per 1000, while in 1902 it was only 4·80 per 1000. But if the death-rate has fallen the invaliding-rate and the sick furlough-rate have both risen considerably. In 1902 the number of permanent invalids was at the rate of 19·1 per 1000 of strength, while no fewer than 10,312 more weakly recruits were sent to their homes temporarily for reasons of health.

THE WAR IN THE FAR EAST.

There is an interesting article in the *Century Magazine* for the present month by Anita Newcomb M'Gee, M.D., under the heading of "How the Japanese Save Lives," which has probably been already read by many medical officers, and, in any case, is well worthy of their attention. Its author acted as supervisor of nurses at the base at Hiroshima, while on the hospital ships, and at the hospitals on the Yalu river, and is therefore able to speak with some authority from special knowledge and personal observation and experience acquired at the seat of war. Dr. M'Gee, in addition to having a good deal to say about the surgery of the war and its results and other points, dwells particularly upon the relative freedom of the Japanese from typhoid fever:—

> Typhoid has been almost [illegible] isolation of every case of typhoid, which is treated as a contagious disease.

There is no reason to doubt the substantial accuracy of these figures and the Japanese medical authorities may well be congratulated on their sanitary successes in this war. It rarely happens, however, that facts work themselves out in this world, and especially in war, after the unerring and unconditioned fashion of a multiplication table. We have, in order to get similarly successful results, not only to follow but to understand the reason of the methods adopted. This in the case of typhoid fever presupposes a knowledge not only of the disease-producing germ but from a prophylactic standpoint of the favouring conditions and fitting soil necessary for its development. The subject is one which lends itself to much legitimate speculation in the present and to further inquiry in the future and the reader is referred to our remarks thereon in another column.

One of the most disabling diseases to which the Japanese are liable is beri-beri. Professor Ward, speaking last week at the Royal Institution on Fungi, said there was a mould which was called "lurking fungi" and generally attacked grain. It was his belief that beri-beri was caused solely by a "lurking fungus" in the rice. This was a very serious thing to eastern nations, especially to an army in the field like that of the Japanese now in Manchuria. He was now awaiting specimens of affected rice from the East for the purpose of proving his suspicions.

As to the progress of the war in the Far East there is no news of any importance to be recorded either from Manchuria or as regards the naval situation. Our knowledge in respect of the latter is altogether so scanty as only to lead to futile speculation. We know neither the position nor the strength of Admiral Togo's fleet and almost as little about that of the Russians. But we may be sure that a good deal of "hard thinking" is being done both sides in preparing for coming deeds both by sea and land.

The general meeting of the Russian Red Cross Society was held on May 7th, when the report of the executive committee was read. After acknowledging the munificent assistance rendered by the various branches of the Imperial family and the nobility and the handsome aid contributed by Germany, France, Bulgaria, &c., the report states that the general total of income from all sources dating from Feb. 9th, 1904, has been 28,840,093 roubles, which with the addition of the reserve capital of the society as at Feb. 9th, 1904, namely, 5,527,183 roubles, makes a grand total of over 32,000,000 roubles—say £3,200,000 in round figures—and this does not include the maintenance of some of the establishments, such as the Finnish and Jewish hospitals, and others mentioned above. It is estimated that the expenditure for the balance of the year from Feb. 9th, 1905, will be about 20,000,000 roubles, and the *Sviet* rather holds out the prospect of the society having to appeal to the State Treasury for assistance, for it is notorious, according to some of the most responsible papers, that the subscriptions are not so generous now as they were in the early stages of the war.

It is expected that the King will shortly visit Aldershot and that His Majesty will in that case be asked to unveil a memorial which has been erected at Gun Hill, near the Cambridge Hospital, to the members of the Royal Army Medical Corps who fell in South Africa.

"Audi alteram partem."

SIR THOMAS BROWNE MEMORIAL STATUE.

To the Editors of THE LANCET.

SIRS,—The statue of Sir Thomas Browne which is being executed by Mr. Henry Pegram, A.R.A., is now well advanced and it is intended that it shall be erected and unveiled in its position in the Haymarket, Norwich, on Oct. 19th of this year, that being the tercentenary of Sir Thomas Browne's birth. The greater part of the cost of the statue has been already subscribed but a further sum of about £100 is still required. The committee therefore venture to send this appeal, trusting that former subscribers will now, after the lapse of such considerable time, kindly assist them by giving a small additional contribution.

Donations will be gladly received by the acting honorary secretary, King-street House, Norwich, or at the bank of Messrs. Barclay and Co., Limited, Norwich.

We are, Sirs, yours faithfully,
PETER EADE, M.D. Lond., Chairman.
W. T. BENSLY, LL.D., } Honorary
CHAS. WILLIAMS, F.R.C.S. Edin., } Secretaries.
FREDERIC R. EATON, Acting Honorary Secretary.
Norwich, May 15th, 1905.

THE AERIAL CONVECTION OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—I notice that your report of my remarks at the Epidemiological Society's discussion on the aerial convection of small-pox makes me suggest that Dr. G. S. Buchanan in his paper suppressed all evidence on the other side of the question. I cannot believe that I suggested anything of the kind nor can I think that the majority of the audience understood me in that sense Dr. Buchanan's allusion to the negative case of Manchester is quite sufficient to clear him of any such charge. I still think that his paper makes by far the strongest case for aerial convection of any yet published. I certainly may have suggested that cases where hospital influence is evident are much more likely to come under the notice of Local Government Board officials than cases where it is not so, but even if I made such a suggestion, that does not imply that facts are "suppressed." I should be much obliged if you would kindly publish this disclaimer.

May I add that, like Dr. A. Newsholme, my attitude on the aerial question is merely that of [illegible] my remarks was rather to sugg[illegible] ment Board recommendations [illegible] and in some cases positively vexatious.

I am, Sirs, yours faithfully,
CLAUDE B. KER, M.D. Edin.,
Medical Superintendent of the Edinburgh City Hospital.
Edinburgh, May 14th, 1905.

THE PROPHYLACTIC INJECTION OF DIPHTHERIA ANTITOXIN.

To the Editors of THE LANCET.

SIRS,—In an annotation under the above heading in THE LANCET of May 13th (p. 1285) the satisfactory results recorded in two recent German papers are described. Such records will, no doubt, be of great service in encouraging others to employ protective injections against diphtheria more frequently and with undoubted benefit to their patients. I should, however, like to point out that, although the results as regards the patient may in most instances be satisfactory, there is a danger in private practice that unless the injections are combined with systematic bacteriological examination the immunised patient may possibly act as a source of infection for others, although apparently free from disease himself.

In the autumn of 1903 I examined a "swab" taken from the throat of a woman who had been attending a fatal case of diphtheria and had received a prophylactic dose of antitoxin about a fortnight previously. It yielded a typical culture of virulent diphtheria bacilli. The patient had herself been free from symptoms but three children with whom she had come into intimate contact had developed the disease. From the throat of each of them I obtained diphtheria bacilli. It is, of course, possible that there is no connexion between the two sets of cases and that the woman instead of being a "carrier," as appeared probable, was herself infected at the later date. Such an experience suggests, however, that it is advisable to take precautions and to combine the prophylactic use of diphtheria antitoxin with routine bacteriological examination until it can be proved that such injections not only protect the recipients but also the community at large.—I am, Sirs, yours faithfully,

Beaumont-street, W., May 15th, 1905. P. J. CAMMIDGE.

TETANUS AND CHLORAL HYDRATE.

To the Editors of THE LANCET.

SIRS,—In the interesting paper by Mr. J. Maberly on the above subject in THE LANCET of May 6th, the writer mentions that he is not aware of any records of such large doses being given without adverse symptoms. It may interest him, therefore, to know that in 1874 Oré[1] injected chloral hydrate in a case of tetanus with successful results. Two intravenous injections of nine grammes each (a total of about 270 grains) were given within a short interval and the dose was repeated on the two following days. The patient passed into a profound state of anæsthesia and eventually recovered. Mr. Maberly's patient received 240 grains within 11 hours, half per os and half per rectum. Other cases are on record but they were not so favourable as Oré's original one. Cruveilhier's[2] patient died during the anæsthesia, after receiving 29 grammes (435 grains) in five days. Abbé's[3] patient became cyanosed after one injection of ten grammes (150 grains) and after consciousness was restored died in tetanic spasms. Oré[4] subsequently used chloral hydrate intravenously as a general anæsthetic, from five to ten grammes (from 75 to 150 grains) producing an anæsthesia of about half-an-hour's duration. In all about from 30 to 40 cases are on record but the dangers of the method were eventually found far to outweigh its usefulness.

I am, Sirs, yours faithfully,
J. M. FORTESCUE-BRICKDALE, M.A., M.D. Oxon.
Clifton, May 13th, 1905.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hollymoor Asylum.

THE Rubery-hill Asylum annexe at Hollymoor was opened on May 6th by the Lord Mayor of Birmingham in the presence of a large assembly. It occupies a site of 120 acres a short distance from the existing asylum at Rubery. It comprises patients' blocks and administrative buildings, a spacious dining and recreation hall, engine and boiler houses, laundry, bakehouse, and workshops, homes for attendants, nurses, and servants, with dining and recreation rooms. There is an attractive Gothic church in the grounds, also an isolation hospital, with the necessary administrative department. As the asylum is to be treated as an annexe of the Rubery-hill Asylum no residence has been built for the medical superintendent but accommodation has been provided between the male and female sides for three assistant medical officers. Lodges have been erected at two entrances and detached residences have been built for the engineer, the head attendant, the gardener, and eight married attendants. The building will be capable ultimately of providing accommodation for 1000 patients but blocks have only at present been erected for 604 patients. Provision for all emergencies has been made. Two rooms at the west end of the church have been provided for patients who may have an epileptic seizure during service. In each bedroom is a telephone and in the door is a window through which the attendant can readily keep a patient under complete observation. Two large tanks capable of holding 29,500 gallons of water are especially kept in reserve for fire extinguishing purposes. The bedrooms are lighted from an electric light in the corridor so arranged that the light shines through a window above the door. The heating of the establishment is by means of low-pressure hot water pipes and radiators heated by steam calorifiers placed in the subways. The hot water supply is heated in high-pressure steam calorifiers placed in the basement of the water tower and is driven by means of pumps to the several draw-off taps. Monotony in colour scheme and decoration has been avoided as much as possible. Reading, music, and games can be indulged in and at one end of the recreation hall there is an ample stage for dramatic performances. Altogether the building is what is claimed for it—a model of its kind.

The Ingleby Lectures.

Departing from the usual custom, the Ingleby lectures were not delivered on a technical subject this year but on a subject of general interest—viz., feeble-mindedness. The lecturer was Dr. James Kerr, the advisory medical officer to the Education Committee of the London County Council. Many of the lay public who are known to be interested in social and educational matters were invited and each lecture was attended by a large and interested audience. Dr. Kerr, after paying a tribute to the memory of the founder of the lectureship, considered the definition of feeble-mindedness and the classification of the various types. He believed that the study of the mentally defective by trained experts using all the methods of psychology, physiology, and clinical medicine would be most useful and be likely to throw much light on normal brain action and development. In his concluding lecture he emphasised the importance of detecting cases of feeble-mindedness in the schools and spoke of the part which heredity, alcoholism, and phthisis played in the production of the condition. For all imbeciles and for most of the feeble-minded he advocated sterilisation at an early age.

The Birmingham Lying-in Charity.

The committee of the Lying-in Charity has issued an appeal for £8000 wherewith to build a nursing home for the training of midwives. £5000 have already been subscribed and the site has been purchased. At the home beds will be provided for certain special cases and arrangements will be made for giving the necessary instruction and enabling it to become recognised as a training centre by the Central Midwives Board. With the exception of the Birmingham workhouse infirmary, where a few midwives are trained, there is no recognised school in the district, and as it is estimated that 10,000 births are managed by midwives in the city each year it is obvious that something must be done to supply the want.

Birmingham Baths and Parks Committee.

At the last meeting of the above committee some interesting figures were given by the superintendent. Last year 621,628 persons were admitted to the baths, an increase of 104,699 bathers compared with the previous year and an increase of 208,630 when compared with 1903. No less than 89 cricket clubs have been registered to play cricket in the principal parks of the city. It is most reassuring at a time when much is said of physical degeneration to hear of so general an indulgence in healthy exercise.

Birmingham, Tame, and Rea District Drainage Board.

A very satisfactory state of affairs was disclosed at the quarterly meeting of the above board. The actual income for last year was £2366 more than was estimated and the actual expenditure was £3870 less than the estimate. In consequence it was decided to make a levy of ½*d.* per tenement less than last year. The opinion was also expressed that the board had now reached the point when the normal increase of tenements and the amount of money received from them would be sufficient to meet their normal increase in the expenditure. The board further decided to do less farming in the future and to adhere more rigidly to the proper work of the board—viz , the disposal of sewage Incidentally it was said that the small townships round Birmingham should be very grateful that they have not to deal with their own sewage and that Birmingham undertakes the disposal of it for them, thereby saving them very considerable expense This drew forth the remark from one member of the board that they were grateful

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Mr Joseph Chamberlain, M P , and the Liverpool School of Tropical Medicine The late Dr J E Dutton

AT the recent festival dinner of the London School of Tropical Medicine Mr Joseph Chamberlain made a flattering allusion to the liberality of Liverpool citizens in the cause of tropical diseases He remarked on the boundless interest he took in the noble work of research carried on in tropical climates and asked, "Why could not London, the metropolis of the empire, the metropolis of the world s commerce, emulate more frequently the generosity of the provincial city of Liverpool? The committee asked for a sum of £100,000, which was a trifle compared with the Liverpool subscription " Mr Chamberlain has always taken a deep interest in the numerous expeditions despatched to the tropics by the Liverpool School of Tropical Medicine and has visited that school on more than one occasion The following letter of condolence has been received by the Liverpool School of Tropical Medicine from Mr Chamberlain —

> [illegible] and occupations have fallen victims on the way leading to the future welfare and prosperity of the great dominions of the King I beg that you will kindly transmit the assurance of my deepest sympathy with the members of his family I am yours faithfully
>
> A. H Milne Esq J CHAMBERLAIN

The Under Secretary of State for the Colonies also wrote saying that Mr Lyttelton desired to express his deep sympathy with Dr Dutton s relatives and his sense of the loss which the Liverpool School of Tropical Medicine has sustained by the premature death of so able and devoted an investigator

Is Lead Poisoning an Accident?

In the Court of Appeal last week the defendants in the case of Steel v Cammell Laird, and Co appealed against an award of the judge of the Birkenhead county court sitting as arbitrator under the Workmen's Compensation Act It appeared that the plaintiff was a caulker in the employ of the defendants In the course of his work he used both red and white lead and the evidence showed that as the result of constant working with these substances his system became saturated with them This set up lead poisoning with its usual results, which totally incapacitated him The county court judge held that this was an accident in the meaning of the Act and awarded the plaintiff compensation Mr C A Russell, K C for the appellants, argued that it was not an accident within the meaning of the statute The injuries in this case were merely the outcome of a process acting injuriously on the system What was contemplated by the Act was an accident the date of which could be fixed, something which could be pointed to as having happened or occurred at a definite time The Master of the Rolls, in giving judgment, said that under the Act an accident was something of the date of which notice must be, and could be given Here if there had been an accident it was quite impossible to point to it and he had come to the conclusion that in the circumstances which had happened here the lesions could not be described as due to an 'accident ' The Lords Justices concurred and the appeal was allowed with costs It was intimated that the case would probably be taken to the House of Lords

The Liverpool Corporation and the Supervision of Stables

The health committee is to be congratulated upon having secured Parliamentary powers to supervise the sanitary condition of stables Only corporation officials are aware of the wretched quarters in which some horses are housed With the new powers obtained the health authority will be able to insist upon the cleanliness and proper ventilation of stables and sufficient cubic space being allotted to each animal Liverpool has frequently taken the lead in sanitary progress and this is another instance of its alertness The Liverpool Sanitary Act of 1846 may be regarded as the pioneer of the Public Health Act

May 16th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

Llandaff and Dinas Powis

THE rural district of Llandaff and Dinas Powis which almost surrounds Cardiff and completely surrounds Barry on the land side of these two towns, has a population approaching 25 000 Dr Richard Prichard (the medical officer of health) in his annual report states that the birth rate in 1904 was 29 9 per 1000, which is about equal to the rate which has been recorded during the previous ten years and is only a little below the Cardiff birth rate, where however, there has been a steady fall in the past decade The death rate in the rural districts during 1904 was 13 8 per 1000, though it is not quite apparent from Dr Prichard s report whether any account has been taken of the deaths occurring in the county asylum A temporary isolation hospital had been in use during the last four years and the district council has now decided to erect permanent buildings at Ely They will be about 200 yards from the Poor law homes belonging to the Cardiff guardians They will include an administration block, two pavilions with two six bed wards in each, and a room for convalescent patients over the nurses central duty room an observation block, laundry, and disinfecting buildings, and a lodge with which discharging rooms will be connected

Health Report for Cardiff

In his quarterly report Dr Edward Walford (the medical officer of health of Cardiff) states that during the first quarter of the year five cases of small pox occurred in the borough Four cases were connected together and one patient was infected in Yorkshire During April two other cases were notified All the patients were treated in the small pox hospital Up to the end of March 96 midwives in Cardiff had received certificates and regulations of the Central Midwives Board 83 as being in practice one year previously to the passing of the Act and 13 on the ground of holding certificates from recognised certifying bodies

Small-pox in Somerset

Several cases of small pox have occurred among the navvies employed in the construction of the new main line of the Great Western Railway from Langport to Castle Cary The village of Charlton Mackrell where the men were working has a population of about 500 persons and is within the area of the Langport rural district, the council of which has made no provision for isolating cases of infectious disease, although the medical officer of health Mr A R Nicholls, has more than once pointed out the desirability of establishing a hospital among a population of 13 000 persons

Treatment of the Unemployed

Whenever boards of guardians meet in conference there is one question which they never omit to discuss It is that which relates to the treatment of tramps and the unemployed At the discussion upon this subject which took place at Llandrindod on May 10th there was considerable difference of opinion among the delegates from South Wales and Monmouthshire boards, not only as to the cause of the large increase in the number of tramps in all parts of the country but also as to the best method of dealing with the problem which this increase has created Trade unions, strikes, lack of technical training, intemperance, and ignorance of cooking were severally given as causes and the popular remedy of labour colonies was advocated One speaker suggested that a genuine working man who had resided in one town for 12 months should be furnished with a certificate by the local authority and upon presenting his credentials to the relieving officer of another district he should be given 1*s* to enable him to obtain food and lodging away from the tramp wards

A Crematorium for Newport

The corporation of Newport (Mon) has approved of the principle of providing a crematorium which it is suggested, should be placed in the public cemetery adjoining the Nonconformist chapel The cost is estimated at £3000 At present Birmingham is the nearest town to which bodies can be sent for cremation.

Workmen's Houses at Aberavon.

During the past five or six years pressure has from time to time been brought upon the Aberavon corporation by the leaders of the workmen living in the town to erect dwellings for the working classes. Aberavon is a small working-class town situated on Swansea bay and contained at the last census 1478 tenements, of which 477 had less than five rooms. If it is assumed that a house is overcrowded when the number of inmates exceeds double the number of rooms in the house there was in 1901 overcrowding in about 9 per cent. of these five-roomed tenements compared with 6 per cent. in Cardiff, 7 per cent. in Margam (which adjoins Aberavon), 11 per cent. in the Rhondda, and 15 per cent. in Merthyr Tydfil. In January last the Aberavon council decided to embark upon a scheme for the erection of 24 houses at an estimated cost for each house of £156, though the cost of land and other charges would bring this amount up to £233. The suggested rental is 5*s.* 6*d.* or 6*s.* weekly. Each house is to contain three bedrooms and there is to be a fixed bath in each scullery. One of the bedrooms measures only six and a half feet by seven and a half feet and the engineering inspector of the Local Government Board, who held an inquiry into the question on May 9th, protested against the provision of so small a room, intimating that the Board would require a rearrangement of the plans in this particular. The rates in Aberavon are now 8*s.* 3*d.* in the £ and have been more than 8*s.* in the £ for several years past.

The Bath "Oliver" Biscuits.

Most people who know Bath have eaten some of the far-famed "Oliver" biscuits. The *Bristol Times and Mirror* of May 13th gives an interesting account of how the name was derived and says that "Dr. Oliver practised in Bath for 40 years. He was a Fellow of the Royal Society but his title to immortality rests upon his invention of the biscuit. He was for 21 years physician of the Mineral Water Hospital and resigned the post in 1761." It is said that he gave the receipt for making the biscuits to his coachman, a man named Atkins, who took a small shop, set up as a baker of the biscuits, and made a fortune. The sale of the biscuits is now so great at home and abroad that a large factory has become necessary.

May 16th.

SCOTLAND.

(From our own Correspondents.)

Bubonic Plague in Leith.

On the evening of May 12th it became known to the public that bubonic plague had appeared in Leith. A man engaged as a labourer on the streets of Leith had died and his widow and two children were ill, it was believed, of the same disease. The man and his family lived near the docks, but he was not engaged in the loading or unloading of vessels. His wife, it appears, worked at a rag store. The case was finally accepted as one of plague after being investigated by Dr. A. K. Chalmers, medical officer of health of Glasgow, and by Dr. R. MacNeil Buchanan, municipal bacteriologist, Glasgow. Both these gentlemen had experience of the outbreak in Glasgow some years ago. No other fatal cases have occurred and no further suspicious cases of illness have been reported. There is no evidence available as to the source of the infection. It does not appear that there is ground for suspecting the rag store as being the source and no rats have so far been caught with any signs of being infected. The public health authorities and their energetic and able medical officer, Dr. W. Robertson, are taking every possible precaution to prevent its spread. On May 16th the Local Government Board for Scotland received a medical certificate officially establishing (1) that, with the exception of the death of the first case of plague—viz., John Hughes, who died in the isolation hospital, East Pilton, on May 11th, 1905—no death from, or fresh case of, plague has occurred within the five days following the isolation, on May 10th, of Mrs. Hughes, being the last case of plague that has occurred; (2) that all measures of disinfection have been carried out; and (3) that measures have been taken against rats. The Local Government Board accordingly, in terms of the International Sanitary Convention of Paris of 1903, has intimated that the port and burgh of Leith will now cease to be regarded as infected with plague.

A Medical Man Elected to the Edinburgh Town Council.

On May 12th Dr. R. Robertson was elected to represent St. Bernard's Ward on the Edinburgh town council in succession to Mr. Lang Todd, whose untimely death deprived Edinburgh of the convener of its public health committee. Dr. Robertson, who defeated a lawyer, stood as a non-political candidate. If he turns out as good a councillor as Dr. G. M. Cullen the profession in Edinburgh will be satisfied.

Glasgow University Council.

When the report of the committee on finance was submitted at a recent meeting of the University Council attention was called to a somewhat important trend in the University finances. The figures given covered nine years and it was gratifying to notice that the income was about £10,000 per annum larger than at the beginning of that period. That sum was almost entirely derived from payments by students whose numbers had increased within the last seven years from 1836 to 2219, or 20 per cent. But more than the whole of the income had gone in meeting the growing demands. During the last two years the University accounts showed deficits due largely to increased cost of maintenance. The increase of expenditure in the last nine years amounted to £9646, of which £5529 was due to increased cost of maintenance. When they considered the new buildings in course of erection they could imagine the enormous increase of cost which must fall upon the University. One of the most clamant needs of the University was some fund that would enable it to meet these growing demands.

Public Health of Aberdeen County.

Dr. J. P. Watt, medical officer of the county of Aberdeen, has issued his report on the health and sanitary condition of the county for the past year. Scarcity of water was experienced in the Bieldside portion of the special district for a considerable time last summer. To meet this an additional supply was got from Bailieswells and two other springs. This addition has proved ample. It has been resolved to construct a reservoir with a capacity of 300,000 gallons to conserve the original or high-service supply. The site of this reservoir has not yet been precisely determined but it is intended to carry out the work this year. Although the springs were abnormally low the supply to the village of Culter was sufficient. The mains throughout the district have been divided into sections by means of valves, so that when a burst takes place or a connexion has to be made the particular section of main can be emptied without cutting off the supply over the whole district as hitherto. This improvement has also been introduced in the Cults water system. The drains have been in much better condition than they were in former years. They have been more frequently flushed and sludge has not been allowed to settle in the pipes. Scavenging has been carried out in a very thorough manner and has greatly improved the condition of the village. In Waterton district, owing to the scarcity of water in the upper parts of the special district, the district committee decided to carry the seven-inch service main up to the reservoir at a cost of £500. This work is now being executed. At the pumping station of the Waterton and Dyce supply, Parkhill, in consequence of the low state of the water power during part of the year, it was found necessary to put down an oil engine as a supplementary power to the turbines. This has proved satisfactory. The scavenging continues to be well carried out. With very few exceptions the privy middens have now been replaced by water-closets. Drainage systems were laid down in Park, Kirkton of Skene, and Balmedie villages by the respective proprietors in the course of the year—an important sanitary improvement. 98 cases of insanitary dwellings, including croft and cottar houses and sleeping places for farm servants, were dealt with in the various districts during the year. During the past year some progress has been made in reference to the pollution of the Don. As mentioned in the last report, the mill owners and the district committee, without prejudice to their rights and pleas, concurred in asking Mr. Curphey (who had previously reported to the Secretary for Scotland on the matter) to advise what, if anything, was necessary to prevent pollution and to render the effluent from the mills innocuous before being discharged into the river. Following on Mr. Curphey's report, the mill owners informed the district committee that they were to carry out his recommendations The district committee understands that considerable progress has been made by the mill owners but for several reasons it is not expected that the purification works will be completed till next summer Progress, however, has been made, and the district committee, when the works have been completed, looks forward to a considerable improvement in the condition of the river The sewage disposal scheme for the Waterton special district is still under the consideration of the district committee A complaint has been lodged by the Fishery Board as to the pollution of the river from various sources The county council has the matter under consideration The number of cases of infectious diseases notified for the year was 537 This is the lowest by about 150 cases since 1898, the year in which the Notification Act came into force, within the county as a whole Of the 537 cases, 241 were cases of scarlet fever, 93 of diphtheria 68 of enteric fever 123 of erysipelas 2 of puerperal fever, and 1 of measles The birth rate was 27 008 per 1000, as compared with 25 828 for 1903 The death rate was 12 538 per 1000, that of the previous year being 13 084

May 16th

IRELAND.

(FROM OUR OWN CORRESPONDENTS)

Tuberculosis in Ireland

ACCORDING to the Registrar General's report published on May 3rd there were registered during the week in the metropolitan area 31 deaths from tuberculosis, of which 17 were attributable to pulmonary tuberculosis It is the usual unpleasant story While the mortality from this disease has fallen in England it has increased in this country and the fact is not surprising since in Ireland there are but two small institutions which even pretend to deal with the fringe of the evil—the sanatorium at Rostrevor and another at Newcastle The county councils generally devote their energies to things political or trivial, but at a meeting of the general council of the county councils on April 28th, presided over by Sir Thomas Esmonde Bart, M P, a new departure was made Mr Thomas Power proposed the following motion which was carried unanimously —

> That in view of the ravages which consumption is making amongst our population it is eminently desirable that steps should be immediately taken to arrest the progress of this dire disease and we recommend to the earnest consideration of the several county and district councils the need which exists in each province for the foundation of properly equipped sanatoria and trust that this all important subject will engage their immediate attention

Something practical may be the result of this resolution for, of course, the county councils have the power to strike a rate and to obtain the necessary money

Maryborough District Asylum

The Maryborough asylum committee at its recent monthly meeting accepted the resignation of Mr Joseph H Hatchell who has been resident medical superintendent for over 37 years He receives the maximum allowance of £533 6*s* 8*d* The salary for his successor has been fixed at £300, with allowances valued at £150

Irish Medical Association

The annual general meeting of the Belfast and District branch of the Irish Medical Association was held in the Medical Institute Belfast, on May 10th when Professor J W Byers was elected [illegible] reference to the much [illegible] Evatt upon the questio [illegible] the secretary read a letter from the central authorities of the association in Dublin to the effect that copies would be sent on application to all members of the association but were to be regarded as confidential The following motion, after a full discussion was proposed by Dr D P Gaussen, seconded by Dr J C Ferguson, and carried unanimously —

> That this branch of the Irish Medical Association is of opinion that the Direct Representative for Ireland on the General Medical Council should if possible be chosen from the ranks of the provincial practitioners

It was moved by Professor J A Lindsay, seconded by Dr A G Robb, and carried unanimously —

> That this branch disapproves of [illegible] ment of the new Irish Medical D [illegible] the association to reconsider these [illegible] the next volume [illegible]

The Royal University of Ireland

On May 10th a meeting of convocation of the Royal University of Ireland was held in Dublin for the election of six members to represent the graduates on the Senate the choice falling upon Judge Shaw, who received 382 votes, Professor Anderson, President of Queen's College, Galway, 365, Dr John Walton Browne, 364, Dr R W Leslie, 340, Professor Leitch, D Lit, 335, and Mr Edward Cuming, 316

Ulster Medical Society

A special meeting of this society was held in the Belfast Medical Institute on May 11th the President Dr W Calwell, being in the chair There was a very large attendance Dr V G L Fielden read a paper entitled "The Pharmacology and Therapeutics of Ice" and Dr J S Darling (Lurgan) showed two cases of Actinomycosis, with microscopic preparations to [illegible] the subject for which t [illegible] was considered—viz, tl [illegible] on the General Medical Council, when the following motion, proposed by Dr C E Shaw and seconded by Dr Darling, was carried unanimously —

> That this meeting is of opinion that the medical practitioners of Ireland should be represented on the General Medical Council by a provincial practitioner and with a view to attaining this we support the candidature of Dr Leonard Kidd

The Royal Medical Benevolent Society

At a meeting of the Belfast branch of the Royal Medical Benevolent Society held in the Medical Institute Belfast, on May 12th, it was reported that £144 had been sub cribed [illegible] there has been an annual fall- [illegible] out of the 200 Belfast medical [illegible] Dr Joseph Nelson was re elected president and Dr R Purdon honorary secretary and treasurer

The Direct Representative for Ireland on the General Medical Council

In addition to Sir William Thomson and Dr L Kidd a third candidate, Dr R B Mahon of Ballinrobe, co Mayo, has appeared He is put forward by the members of the County Mayo branch of the Irish Medical Association on the ground that it is intolerable that the Poor law medical men should be any longer unrepresented on the General Medical Council In a circular issued by the County Mayo branch it is said that "the meeting [of the branch held in Claremorris on April 27th] considered that while the thanks of the Poor-law medical men of Ireland are due to Sir William Thomson for his efforts on their behalf, so many portals exist for his admission to the General Medical Council that it is unlikely that body will be for long without his assistance in the event of his non election as Direct Representative" It is also stated that in the event of any other Poor law candidate coming forward a preliminary poll should be arranged to decide who goes to the final poll It is clear that the coming contest for Direct Representative for Ireland on the General Medical Council will resolve itself into the issue of the provinces *versus* Dublin and that the medical men outside the metropolis will favour the claims of a general practitioner and preferably one who is in thorough sympathy with the grievances of the Poor law medical officers

(FROM OUR OWN CORRESPONDENT)

Trypanosomiasis in a White Man

AT the meeting of the Academy of Medicine held on April 25th M Laveran referred to a case of trypanosomiasis in a white man He reminded his hearers that sleeping sickness was only one of the many forms of trypanosomiasis so frequently met with in equatorial Africa and that early observers had thought that it was peculiar to the black races but that of late years, since white men had penetrated in greater numbers into those regions, several cases had occurred in Europeans The case to which he referred was one reported by M Martin and M Girard and the patient was a French missionary, aged 38 years, who contracted the disease in the French Congo He went there in 1891 and [illegible] d to France shortly after the commencement of his [illegible] in 1904 The illness began with marked asthenia, anæmia, and general weakness but there was very slight fever. He also suffered from an intensely itchy papular eruption which could not be assigned to any parasite. He was sleepy and dull and had subsultus tendinum. A blood count showed eosinophilia 12 per cent. and trypanosomata were found in the blood. The remainder of his system (*appareils*) was normal but the blood and the cerebro-spinal fluid were contagious by inoculation in the rat and the guinea-pig. At the end of some months the patient died; nightmare and delirium were present but there was neither coma nor lethargy. This is interesting in view of the fact that the *only pathogenic agent found was the trypanosoma Gambiense*, contrary to the opinion of Manson who holds that sleeping sickness is a bacterial disease and only supervenes as a complication of trypanosomiasis. It would seem that sleepiness, coma, and lethargy correspond pretty accurately to three degrees of alteration of the brain tissue in patients suffering from trypanosomiasis and that if the last two are wanting in the white man it is because he is more sensitive than the black man to the infection of the trypanosoma.

Spontaneous Gangrene of the Leg in Popliteal Aneurysm.

At a recent meeting of the Society of Surgery M. Arrou communicated an account of a case which showed that when gangrene followed on an operation for extirpation of a popliteal aneurysm it was not always just to blame the operation. M. Arrou said that every popliteal aneurysm should be operated on and that one should never be afraid of operating lest gangrene should supervene, for gangrene might occur in such cases without any operation. He mentioned the case of a woman, aged 50 years, who came to consult him for a small tumour in the popliteal space. M. Arrou finding that it was an aneurysm recommended operation but the patient refused. One month later she returned with gangrene of the whole of the leg which necessitated amputation through the middle third of the thigh. The operation was performed without the loss of one drop of arterial blood and the femoral artery was completely blocked with a hard dry clot. For prudential reasons a ligature was placed on this vessel but this was the only ligature used. What was still more astonishing was that the wound healed by first intention and that there was not the least sloughing of the flaps.

The Influence of Children's Dispensaries on Infantile Mortality.

At the eleventh session of the Obstetrical Society of France M. Mocquot stated that sound directions as to suckling or bottle-feeding (*allaitement*) children did not only serve to diminish the frequency of gastro-intestinal affections but had an influence upon other maladies so that they tended to diminish in both number and gravity. M. Budin gave some figures as to infantile mortality in various regions of France and in other countries. They showed a lowering of infantile mortality in towns where there existed children's dispensaries (*consultations des nourissons*). In Paris, for example, although the temperature was higher and remained higher for a longer period in 1904 than in the two preceding years, infantile mortality underwent a marked diminution. The same thing was even more marked in smaller towns, but such a state of affairs by no means obtained in towns where these dispensaries did not exist.

Radiotherapy in the Treatment of Eczema.

At the meeting of the Academy of Medicine held on April 25th Dr. Leredde read a note upon the usefulness of radiotherapy in eczema, even in those forms which affect the skin deeply. In one case in which the face was affected the disease had lasted 15 months; in another the disease, which had commenced in the hands some two years previously, had spread to the face and to the thighs. In both patients all treatment had failed. After several sittings of radiotherapy a cure was obtained and had already lasted for four months. In a third case the relief was only temporary. Dr. Leredde said that radiotherapy seemed to offer a means of treatment of great value for grave cases of eczema, especially those which for one reason or another were pronounced incurable.

The International Tuberculosis Congress.

From Oct. 2nd to 7th next a grand International Congress against Tuberculosis will be held in Paris. The opening session will be held at the Grand Palais, the honorary presidents being M. Casimir-Périer and M. Léon Bourgeois, while the President of the Republic is patron. A sum of 100,000 francs has been voted by the Chambers. The nature of the researches to be undertaken, the scope of the publications, and the official receptions which will be offered to those attending the Congress all justify the effort which the State and the whole body of French men of science are going to make. The Congress will not confine itself to the medical aspects of tuberculosis but will also discuss the social side of the question and will make an appeal for the coöperation of all classes of society in the fight against the disease. 25 local committees outside Paris have been already constituted and 33 foreign countries have organised national committees. In connexion with the Congress *will be held an exhibition illustrative* of the anatomy and bacteriology of tuberculosis, together with statistical documents and literature concerning methods of prophylaxis and the like. There will also be a commercial and industrial section. The exhibition will be open to the public throughout the month of October.

May 16th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Cerebro-spinal Meningitis.

CEREBRO-SPINAL meningitis is now extremely prevalent in Upper Silesia. This disease, which had nearly disappeared for about 30 years, has spread through several districts of that province and cases have made their appearance sporadically in various parts of Germany. There is, therefore, some uneasiness among the public caused especially by the reports of the lay press, so that even in Berlin and its neighbourhood, where about ten cases may have occurred, patients suffering from a chill or rheumatic pains in the muscles of the neck are likely to imagine that they have caught cerebro-spinal meningitis. In Silesia up to the present time 1955 cases have been notified and of these patients about 50 per cent. have died. As in former epidemics, it has been observed that the disease is not so contagious as some others and that school children who are especially liable to catch measles and scarlet fever are not exceptionally susceptible to cerebro-spinal meningitis. Energetic measures have been taken to check the spread of the disease and ample hospital accommodation has been provided. Unfortunately the inhabitants of Upper Silesia are accustomed to a low standard of living and pay little attention to hygienic principles. The district is, moreover, a mining centre and very overcrowded, most of the people being Poles.

The Roentgen Congress.

Immediately after Easter no less than three medical congresses were held in Berlin. The Congress of the German Surgical Association met as usual from Wednesday to Saturday after Easter, being preceded by the recently founded Congress on Orthopædic Surgery which assembled on the Tuesday. In the following week—namely, from April 30th to May 3rd—a Roentgen Congress on radiography took place. *Professor* Roentgen, the honorary President, was expected to be present but did not appear, the reason being, as was generally supposed, his disinclination to be a prominent figure at a public meeting. After the inaugural address, delivered by the Vice-President, Professor Eberlein of the Berlin Veterinary College (the President, Professor von Bergmann, being absent in Italy for his health), and the addresses of welcome on behalf of the various official authorities and medical societies, the proceedings began with general reports on the importance of the Roentgen rays in the different branches of medicine and surgery. *Professor* von Leyden first spoke on radiography in internal medicine, especially in diseases of the nervous system. He said that by radiography it was possible to examine the vertebral column and in this way useful information might be obtained in diseases of the spine. Professor Grunmach explained the methods of radiographical examination in diseases of the internal organs, especially of the heart and the lungs. Professor Hoffa spoke on the advances in orthopædic surgery attained by the aid of radiography. He made especial reference to congenital dislocation of the hip-joint, to scoliosis, and to spondylitis, in which an exact diagnosis was made early by radiography. Professor Lenhartz and Dr. Kisorling communicated a paper on the *Diagnosis* of Gangrene of the Lungs by Radiography. They said that this method enabled surgical operations to be *performed* with greater security because the situation and the extent of the gangrene could be ascertained By surgical operation the mortality of this disease has been reduced from 90 to 65 per cent The application of the Roentgen rays for curative purposes was the subject discussed at the last meeting Professor Lassar of Berlin spoke on the cure of superficial cancroids by the rays He said that in the early days of radiography the exposures were often too long and "burns" of the skin were the consequence It was now possible to avoid these drawbacks and to use the rays not only as a means of diagnosis but as a powerful remedy This has especially become evident in the treatment of cancroid, where the success of radiography could not any longer be denied Superficial cancroids might heal after a few exposures and relapses might be similarly treated with a good result On microscopical examination a destruction of the cancer cells was found to occur after the irradiation It must, however, always be kept in mind that the effect of the rays did not exceed one centimetre of depth so that the deeper layers were not influenced Radiographical treatment was also useful in cases where a relapse had occurred after an operation In these cases it was possible by the application of the rays to bring about healing of the ulcerated spots and to relieve pain, although there was no means by which relapsing malignant growths could be made to disappear In the discussion Dr Colley expressed the opinion that by the alleged success of Roentgen treatment of superficial cancer the public might be led to believe that irradiation ought to be tried first in every case of cancer and in this way the right moment for an operation might be missed Dr Unger of Berlin said that not only the successful but also the unsuccessful cases ought to be published He mentioned some cases where under the Roentgen treatment the growth had extended into the deeper layers of the tissue Dr Strebel of Munich discussed the therapeutic effect of cathode rays He said that the cathode rays produced very severe dermatitis which might last for several months but finally healed The energy of the cathode rays exceeded that of the Roentgen rays and even that of radium They were especially suited for the treatment of lupus, cancroid, and telangeiectasis It was especially remarkable that the cathode rays might be introduced into the cavities of the body, so that diseases of the rectum and of the uterus might eventually be treated by this method Apart from the medical meetings a day of the Congress was devoted to the technical side of radiography, when improvements in the apparatus, &c , were demonstrated International uniformity in the technical terms to be used in radiography was recommended The result of the Congress was finally the foundation of a German Roentgen Association

VIENNA

(FROM OUR OWN CORRESPONDENT)

Open Spaces round Vienna

AT a recent meeting the municipal council adopted a scheme which will have an important effect in promoting the salubrity of the atmosphere of the city The intention is to surround Vienna with a belt consisting of a continuous series of gardens, recreation grounds, woods, and meadows, which will be formed at the joint expense of the city and the empire This belt will have a breadth of about one kilometre and a length of 40 kilometres, thus providing an area of not much less than 20 square miles, on which no building will be allowed to stand Part of the belt exists already in the south and east of the town but the necessity of completing it has become apparent through the erection of the new hospital

The Street Ambulance Corps

The Street Ambulance Corps has just opened a new station in proximity to the western suburbs The central station being situated on the south of the city the ambulance vehicles had to make a journey of several miles in order to reach some of the outlying districts, so that the western station will be a decided acquisition It contains accommodation for five carriages, with stabling for the horses, and besides the necessary rooms for the medical officers there are a small operating theatre for minor surgery, a sterilisation room, and a library An electric motor car, specially designed for the use of the ambulance corps and fitted with all requisites for first aid and for the conveyance of patients to hospital, has been provided The officers of the corps deliver lectures on first aid, chiefly for the instruction of the police force but also for the benefit of the working classes The corps is under private management and was founded in consequence of that fearful disaster the burning of the Metropolitan Theatre 20 years ago when 800 people perished from want of an organised institution of this kind

Treatment of Hypertrophy of the Prostate by the X Rays

At the last meeting of the Vienna Medical Society Dr Moszkowicz showed several cases of Enlargement of the Prostate in which he had tried a new method of treatment As the enlargement was due to the hypertrophy of the glandular tissue chiefly, and as this tissue was easily influenced by the x rays, he directed the rays of a "soft" tube through the rectum towards the gland Of three men who were shown the first was 66 years old, and after three exposures, each lasting 15 minutes, he was able to pass urine spontaneously The second patient was 77 years old and his prostate was enormously enlarged and very hard The same treatment was adopted and now he can pass urine freely but some of it is still retained The third patient was completely cured Two of them had severe hæmorrhagic cystitis and one had epididymitis after 17 days It was difficult to say whether these complications were the effects of the rays As regards the technique a rectal speculum was used and the surrounding parts were covered by lead Dr Moszkowicz intended in the future to use bromide of radium which might be applied by means of an ordinary catheter and could be directed exactly towards that part of the gland which compressed the urethra

University of Vienna

In this University the summer semester begins on May 1st, and quite a number of interesting lectures will be delivered in the different wards and institutions The fees for these courses vary between 25 and 100 kronen (between £1 1*s.* and £4 4*s*) Several lectures will be delivered in English, if a sufficient audience preferring that language present themselves, otherwise they would naturally be delivered in German Surgical courses, with special reference to atypical operations, and courses on the surgery of the uropoietic system, of the ear, and the nasal accessory sinuses, will be conducted by a number of eminent specialists such as Professor Zuckerkandl, Professor Urbantschitsch, and Professor Pollitzer Professor Nothnagel and Professor Neusser will lecture on medicine and several professors including Dr Chiari, will lecture on laryngology Bacteriology, serum therapeutics, and hygiene are well provided for in the new Pasteur Institute of Vienna Operations on the eye, gynæcological operations, and obstetrics can be learned very conveniently as the clinical material at the disposal of the respective clinics amounts to several thousand patients yearly The summer term lasts only till the middle of July and therefore it is advisable to come to Vienna in the winter semester, when the time available for study is over five months—namely, from the middle of October to the end of March and when the clinical material is greater But the summer is at least pleasanter for theoretical courses, such as those on histology and physiology

NEW YORK.

(FROM OUR OWN CORRESPONDENT)

The Abolition of the Cigarette in Indiana

THE legislature of Indiana has recently enacted a law making it a misdemeanour to sell cigarettes and punishing those who have them or the paper used in rolling them in their possession This high handed procedure on the part of the Indiana law makers has been variously received in different parts of [illegible] the action as one taken in [illegible] lth, while others brand it as the [illegible] iacs The *New York Times* takes the latter view and explains editorially that cigarette smoking is probably the least harmful form of that habit The opinion is expressed that the Indiana cigarette law is an outrage in its invasion of personal liberty and its interference with legitimate trade The question of the harmfulness of cigarette smoking has been threshed out in a fairly thorough manner in THE LANCET on several occasions The general conclusions arrived at were that cigarette smoking, *per se*, was no more injurious than the use of tobacco in pipe or cigar Cigarette smoking in

THE MIDWIVES ACT AND THE PAYMENT OF FEES TO MEDICAL MEN.—We have been requested to publish the following resolution of the Islington Medical Society, moved by Dr. Basil G. Morison and seconded by Dr. L. U. Young:—

> That we, the members of the Islington Medical Society, are of opinion that immediate arrangements should be made under the Midwives Act in the interest of lying-in women of the poorer but not pauper class for the prompt attendance of a registered medical man in cases of abnormality, and that the payment of such attendance should be made by the metropolitan borough councils or, failing them, by the County Council, with powers of recovery where this is possible.
>
> Signed, on behalf of the meeting,
>
> JAMES GREY GLOVER, Chairman.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE.—A meeting of the Faculty of Medicine will be held at the University of London on Tuesday next, May 23rd, at 5 P.M. An interim report from a special committee appointed to consider the subject of teaching and research in the "advanced subjects" of medical education will be submitted. As a first step towards securing an improvement in the teaching of the "advanced" or clinical subjects of the curriculum—viz., medicine, surgery, midwifery, &c.—the committee recommends the Faculty "to press upon the Senate the desirability of such a modification of the University regulations as will admit of a much longer period being allotted for 'advanced' studies and a proportionate curtailment of the time allotted for the early studies." A second special committee will present a report embodying proposals to secure a definite plan of annual retirement by a proportion of the members of certain boards of studies comprised within the Faculty.

UNIVERSITY OF OXFORD: DEPARTMENT OF OPHTHALMOLOGY.—A post-graduate course on ophthalmology has been arranged from July 3rd to 15th. The main idea of the course is to demonstrate (on actual patients as far as possible) the whole range of ophthalmology, in order to make the reading of a text-book more profitable than can be the case when relying merely on pictures. The first week will be mainly devoted to demonstrating the practical examination of eye patients, the use of the ophthalmoscope, and the work of refraction. During the second week the work will be more specialised. As well as the mere routine cases there will be a large selection of cases of unusual interest for the benefit of those who are more experienced in eye work. The lecturers are the reader in ophthalmology, Mr. R. W. Doyne, Sir William J. Collins, Mr. W. Adams Frost, Mr. E. Nettleship, Mr. Sydney Stephenson, Mr. C. A. Worth, Mr. R. M. Gunn, Dr. S. J. Sharkey, Mr. Priestley Smith, Mr. E. Treacher Collins, and Mr. J. H. Parsons, and Professor William Osler is to be asked to give an address. In addition to the above lecturers several ophthalmic surgeons have undertaken to give clinical demonstrations. The course will be illustrated by the lantern. The fee for the course is five guineas. Gentlemen attending the course will be provided with board and residence in Keble College at the rate of 7*s.* 6*d.* per day. For further particulars application should be made to Mr. Robert W. Doyne, 34, Weymouth-street, London, W. Early application is desirable as the numbers must of necessity be strictly limited.

NATIONAL SANATORIUM FOR CONSUMPTION, BOURNEMOUTH.—The fiftieth annual meeting of the governors of this sanatorium was held on May 11th, the Earl of Eldon presiding. The annual report of the committee of management stated that the extension of the building and alterations and improvements by which 14 beds had been added for patients and better accommodation provided for the nursing staff had cost over £3000, towards which only £2000 had been subscribed. The ordinary income for 1904 had amounted to £2999 and the ordinary expenditure to £3094, but the expenditure had been abnormally low owing to the closing of the sanatorium for four months in consequence of the building extension. The committee was anxious to commemorate the jubilee of the institution by placing it in a sound financial condition and it appealed for new annual subscriptions to meet current expenses and for donations to pay off the total debt of £1500. Nearly 300 patients had been under treatment, a very large proportion of whom had been discharged considerably improved. The meeting deplored the death of Mr. Charles Lavington Pannel, mainly through whose efforts the National Sanatorium was founded and who took an active part in its management until advancing years prevented him. It was resolved that in future donors of £500 should have the right to name a ward, and donors of £100 the right to name a bed, in perpetuity.

HOLIDAY GUIDES.—Guides to Aberystwyth, Bournemouth, Broadstairs, and Southport, well illustrated and containing useful information for intending visitors, can now be obtained free on application to the town clerks of the respective watering places.

BY permission of the Worshipful Company of Carpenters an exhibition of the competitive plans and drawings for the new buildings of King's College Hospital at Denmark-hill will be held in the court-room of the Carpenters' Hall, London-wall, E.C., from May 26th to June 1st. The exhibition will be open on May 26th from 12 noon to 5 P.M. and on the five remaining days from 10 A.M. to 5 P.M., except on June 1st, when it will close at 4 P.M. The presentation of a visiting card will admit to the exhibition.

THE HIGHER EDUCATION OF NURSES.—The Board of Trade, having received an application for the registration of an association for the promotion of the training and of the higher education of nurses as a company without the word "limited," invited anyone who objected to the application to state his reasons for objecting in the deputation room of the Board of Trade, 7, Whitehall-gardens, London, on May 5th. The room was filled to overflowing with people who had come to object and many inquiries were made by the ladies present as to whether the promoters of the company were going to speak. The names of these gentlemen were Lord Rothschild, Lord Revelstoke, Mr. H. Cosmo Bonsor, Mr. E. A. Hambro, Mr. C. H. Goschen, Mr. S. Hope, and Mr. C. H. Smith. But to those sitting at the back of the room it was only possible to make out that Mr. H. Cosmo Bonsor was there. The meeting commenced at half past eleven in the morning and did not finish till about two in the afternoon, most of the time being taken up by objectors. The gentleman who represented the Board of Trade very plainly told the meeting that he was there to hear objections to the application of the promoters of the company for the registration of the company without the word "limited." The only person who seemed to address himself to this point was a gentleman who claimed to be the representative of 15 hospitals and as far as could be made out at the end of the room his argument was that to omit the word "limited" would give an authority to the proposed company which it would not secure if it always had to put the word "limited" after its name. Sir James Crichton-Browne, who was understood to appear on behalf of 2800 nurses, said some hard things about the proposed company. He declared that its very constitution was vicious in principle and as for the objects of the company they were simply opposed to all sound policy. Even the promotion of the company was wrong because, according to Sir James Crichton-Browne, it was a gratuitous infringement of the rights of the nurses whom he championed: In short, this new company was inopportune in its inception and would prove injurious to the public and to the whole of the nursing community. Sir J. Crichton-Browne was very caustic in his remarks on the provision made by the suggested company for the registration of nurses and wanted to know in what way the promoters of the company were fitted to be members of a council to which disciplinary powers over nurses were to be granted. Mr. Sydney Holland was much cheered by the nurses present, especially those at the end of the room. He was very severe on the gentlemen who launched this new company and in regard to the regulations for registering nurses he said there was a word in the English language known as "cheek," but apparently he did not wish to apply that term out of respect to Mr. Cosmo Bonsor, who, however, smiled very pleasantly and did not seem to mind at all. Every society connected in any way with nursing seemed to have sent some one to urge an objection. There were ladies who represented matrons' councils, and ladies who attended as delegates from working nurses, and there was Mrs. Bedford Fenwick who very solemnly warned the Board of Trade against granting the desired licence to the company. Dr. Bedford Fenwick also spoke and the Vice-President of the Royal College of Surgeons in Ireland said that the proposed society would be mischievous and its government degrading. Sir Victor Horsley said only a very few words but they were listened to with the closest attention. His message from the British Medical Association was one of absolute hostility to the proposed company and its registration of nurses He observed that medical men had suffered so much from companies that they could not allow the nurses to be exploited in the same manner without raising the strongest protest against such an iniquity Sir Victor Horsley also wanted to know how it was that the company had come out with two prospectuses and these two differing in regard to who were the people to manage the registration of nurses and to judge in regard to *nurses being struck off the register* Mr *Cosmo Bonsor told* the meeting how it was that two prospectuses came out and then proceeded to answer what had been said by Mr Sydney Holland and others His answers, however, only evoked further questions and further objections and everyone was apparently glad to get away after the representative of the Board of Trade had poured oil on the troubled waters and promised to report all that had been said to Lord Salisbury.

THE SOCIETY OF ARTS AND THE LONDON INSTITUTION —In view of the feeling which appears to have been aroused amongst some of the proprietors of the London Institution with regard to the proposed amalgamation with *the Society of Arts*, and the consequent probable difficulties of [illegible] two corporations int[illegible] he Society of Arts has [illegible] in the matter and has discharged the committee which, at the instance of the board of managers of the London Institution, it appointed to consider the scheme for amalgamation

ROYAL SANITARY INSTITUTE.—The institute dinner was held in the Prince's Restaurant, Piccadilly, London, on May 12th, His Grace the Duke of Northumberland, K G., the President, being in the chair There were 108 members and guests present, amongst whom were the Bishop of Hereford, Sir R Douglas Powell, President of the Royal College of Physicians of London Sir Henry C. Burdett, K C B ; Sir William J Collins, chairman of the education committee of the London *County Council*, *Sir Arthur W Rucker, LL D, F R S*, Principal of the University of London, Sir George Hare Philipson, LL D, Principal of the Durham College of Medicine; Sir Alexander Binnie, President of the Institution of Civil Engineers; Sir Shirley Murphy, medical officer of health of the County of London, Director General Herbert Mackay Ellis, Royal Navy Medical Department, Mr Augustus O Scovell, J P, chairman of the Metropolitan Asylums Board, Mr. Andrew Clark, chairman of the council of the British Medical Association, Dr J F J Sykes, President of the Incorporated Society of Medical Officers of Health, and *Colonel* J *Lane Notter*, R A M C, *chairman of the* council of the institute The Duke of Northumberland, after outlining the work carried on by the institute, said "With regard to the new buildings, the penalty of so much success is that we grow out of our clothes The council has decided, therefore, that we must go to the tailor You know well that we have a valuable museum and library, that we have much work in the way of lecturing and training in sanitary science, in examining those who will submit themselves for examination, and in levelling up the sanitary position of those who have the charge of health throughout the country and I think, and the council thinks also, that the time has come when it is necessary to have more room You have had a scheme laid before you to acquire a very excellent site in an important part of London where it would be possible for us to erect a building which would meet with our need. We have a certain amount of money towards that—about £10,000—but we want £15,000 more if we are to enter upon it That is a very serious amount to raise but I cannot help thinking that if each of us does his best to meet the demands of this kind, and if we appeal to all those throughout the country who really appreciate the work that we are doing, it may not be impossible to reach that sum and put the Royal Sanitary Institute in a position locally which shall be worthy of its great achievements" Colonel J. Lane Notter said "To further develop this great work your council find it necessary to move into larger premises as they are terribly handicapped in Margaret street for want of room The proposed site has been circulated to the members but it is not the intention of the council to adopt this or any scheme without taking the members of the institute into the [illegible] position [illegible] fellows, [illegible] present appeal for funds So far I am happy to say that the proposed scheme appears to appeal to all classes of members and a number of donations have been received from associates, many of them of limited means, but who have promised small annual subscriptions" The Bishop of Hereford said that the homes of the working classes, both in town and country, ought to be far more sanitary One of his clergymen had told him that in his parish of 4000 there were no less than 120 homes that were not fit for the upbringing *of children Priding themselves as they did upon their imperialism* it was high time that they looked to the welfare of these younger members of the empire

AN AMERICAN CENTENARIAN —The *Boston Medical and Surgical Journal* of May 4th states that Hiram Cronk, the sole survivor of the war of 1812, who lives at Dunn Brook in Central New York, celebrated his 105th birthday on April 29th and that a number of delegations from patriotic societies visited him on this occasion

SOCIETY OF ARTS.—Dr. Charles Creighton, author of the "History of Epidemics in Britain," read a paper before the Indian Section of the Society of Arts on May 18th on Plague in India Dr Creighton has recently visited India for the purpose of studying the general aspects of plague and his paper, besides dealing with the present situation, referred to the probable course of the infection according to historical precedent

CHILDREN'S COUNTRY HOLIDAYS FUND —The *annual meeting of this fund* (18, *Buckingham street, Strand*, W C) will be held at 3 30 P M on Monday next, May 22nd, *in the Hotel Métropole* The Earl of Erroll will preside. [illegible] the Bishop of Stepney, Mr. [illegible] Edmund Talbot, and Miss N [illegible] *for the Colonies* Mr. Lyttelton, who is one of the trustees of the fund, is also expected to be a speaker

COUNTRY SCHOOLING FOR TOWN CHILDREN.—A movement was started in Manchester some time ago, by the Rev S Nugent Perry, for the establishment of a country school "for those Manchester children whose homes are far removed from anything that speaks of rural life." His parish furnishes very few children who would not be included in the above category and though the ignorance of a world outside the wilderness of bricks and mortar to which the child of the slums is accustomed has often something quaint and humorous it is also pathetic The outcome of the movement culminated recentl[illegible] school at Knoll's Green, near [illegible] Hoy, chairman of the Manch[illegible] *on the invitation of* Mr. Herbe[illegible] of which he is chairman There [illegible] the permanent charitable societies of Manchester and the school is looked upon as an experiment The gentlemen present were of various shades of opinion but all joined heartily in this effort to bring out some of the scholars and their teachers from time to time from the town to the country In an address given by Lord [illegible] the view that there was [illegible] children and said that [illegible] much more favourable [illegible] than before the *factory* legislation, when "we had child labour pushed to an extreme" There is happily more interest taken in the conditions of life among our town dwellers than ever before but the recruiting *returns, to say nothing of other* evidence, show that there still is a good deal of leeway to make up

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Canine League.

ONE of the incidents of the sitting of the House of Commons on May 11th was the presentation of a petition by Mr ELLIS GRIFFITH and Mr MACNEILL from members of the Canine League and others against vivisection The petition bore 180 000 signatures, was two and a quarter miles in length, and weighed over a hundredweight.

HOUSE OF LORDS

THURSDAY, MAY 11TH

Public Health Acts (Amendment) Bill.

Lord HYLTON, in moving the second reading of this Bill, explained that its objects were to exempt buildings sufficiently isolated from the

the incompetency of nurses. The same remark would apply to district committees and college hospitals and so on. The danger lay in the way nursing institutions were worked and in the way women advertised; those institutions should undoubtedly be under some control. With regard to a nurse's recommendations they had no guarantee that they were correct unless there was a register. Some time ago a woman applied to him. She said that she was a trained mental nurse. He asked what her training consisted of and she told him that her late husband was a policeman. He had had something to do with the cells and that was her sole training.

Answering Sir John Stirling-Maxwell, who inquired what steps the Central Board would take in the case of a nurse who grew rusty, he said he would never remove her from the register except for sufficient cause or at her own wish. He would ask a nurse to report herself every two years. The register would give a guarantee that she had been properly trained and that she had not been guilty of any culpable offence. He wished nurses to have their own certificates and private recommendations just as at present. A mere directory would not answer the purposes they had in view. It would ignore the examination.

Sir John Tuke: Why should you institute a second examination for nurses who are found qualified by institutions?—To secure uniformity.

The committee then adjourned.

BOOKS, ETC., RECEIVED.

Adams Bros., 59, Moor-lane, E.C.

The Physiological Aspect of Dietary. By A. S. Wauchope-Watson. Price 2*s.* 6*d.*

Price per set: extra cloth, £6 6*s.*; half leather, *marble sides and edges, £7 7s.; half morocco, £8 8s.*

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Alford, E. Frank R., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at the Paddington Green Children's Hospital, W.

Allen, James D. C., M.B., C.M. Edin., has been appointed Public Vaccinator and Medical Officer to the Binfield District of the Easthampstead Union.

Anderson, John, M.D. Aberd., has been appointed Officer of Health for the East Riding of the Council Shire of Ballan, Victoria, Australia.

Baird, John C., M.B., Ch.B. Melb., has been appointed Officer of Health for the Shire of Healesville, Victoria, Australia.

Beaumont, W. H., M.B., B.S. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Sedbergh District of the county of York.

Cross, W. Foster, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed an additional Non-Resident Anæsthetist at St. Bartholomew's Hospital.

Gray, Walter Gordon, L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer of Health for the Holsworthy (Devon) Urban District Council.

Harris, John, M.D. Aberd., has been appointed Honorary Assistant Physician to the Sydney Hospital, New South Wales, Australia.

Lawson, T. C., M.R.C.S., L.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Stokenchurch District of the county of Buckingham.

Lock, John Lewis, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Medical Officer of Health of the Uxbridge Urban District.

Macknight, Charles Crawfurd, M.B. & Ch.M. Edin., has been appointed Officer of Health for the Shire of Warrnambool, Victoria, Australia.

Manby, W. E., M.B. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bridport District of the county of Dorset.

Saundby, Robert, M.D. Edin., F.R.C.P. Lond., has been appointed Consulting Physician to the West Bromwich District Hospital.

Sinclair, Thomas Walker, M.D. Melb., has been appointed on probation for six months as Assistant Medical Officer of Health for the Metropolitan Combined Districts, New South Wales, Australia.

Smyth, E. J., M.D., B.S. Lond., has been appointed Honorary Ophthalmic Surgeon to the Royal Surrey County Hospital, Guildford.

Trenfield, George Henry, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Almshouses under the management of the trustees of the Bristol Municipal Charities.

Watkins, W. L., L.K.Q.C.P. Irel., has been appointed Medical Superintendent at Yarra Bend Asylum, Victoria, Australia.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Auchterhouse, Sidlaw Sanatorium.—Medical Superintendent. Salary £250 per annum.

Bethlem Hospital.—Two Resident House Physicians, unmarried, for six months. Honorarium at rate of £25 per quarter, with board, lodging, and washing.

BIRKENHEAD BOROUGH HOSPITAL—Junior Resident House Surgeon Salary £80 and fees.

BODMIN, CORNWALL COUNTY ASYLUM.—Junior Assistant Medical Officer. Salary £135 per annum, rising to £155, with board, lodging, &c.

CANCER HOSPITAL, Fulham road, S W.—Assistant House Surgeon for six months, renewable Salary £70 per annum, with board and residence.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn road, W C—House Surgeon. Salary at rate of £50 per annum, with board and [illegible]

[illegible] Salary £70, with board, residence, and washing. Also Eight Clinical Assistants [illegible]

[illegible] Physician.

WEST LONDON HOSPITAL, Hammersmith road, W.—House Physician for six months Board, lodging, and laundry provided

WINSLEY, NEAR BATH, SANATORIUM FOR POORER CONSUMPTIVES—Resident Medical Officer, unmarried. Salary £200, rising to £300

THE Chief [illegible], gives notice of a vacancy [illegible] ory and Workshop Act at [illegible]

Births, Marriages, and Deaths.

BIRTHS.

THORNTON—On May 13th, at 3, The Beacon, Exmouth, the wife of George Lestock Thornton, M A Cantab, M R C P. London, M R C S, of a daughter.

UPWARD—On May 13th, at Edfou, Romford, the wife of Harold Upward, M B., M R C S, of a son.

MARRIAGES.

[illegible] C H [illegible] Rev. J. Hallward, Edgar Hugh Strong, M.R C S Eng, L R C P Lond, youngest son of Lieut Col. Owen H. Strong, of 'Monard, Knole road, Bournemouth to Agnes Beryl, third daughter of W A. H. Holland, Esq, J.P., of Grahamstown, Cape Colony (By cable)

DEATH.

LANGWILL.—At 4, Hermitage-place, Leith, on May 13th, Amy Holmes, wife of Hamilton Graham Langwill, M.D, F R C P E

N.B.—A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL EVIDENCE AT CORONERS' INQUESTS

To the Editors of THE LANCET.

> "Search to the core and with the sharpest knife
> The secret of the soul's escape from life"—*Culpepper*.

SIRS,—Every lover of diagnosis and vital statistics must regret that a post-mortem examination was not ordered in this Stepney case (*vide* THE LANCET, May 6th, p 1243), although the ordering of a necropsy is purely at the discretion of the coroner No doubt Mr. Baxter had his reasons for not having one but every medical man of to-day is credited with the ability to make a post-mortem examination in an every day case Now some coroners, notably Mr Troutbeck, do not think so, for they do their best to supersede the general practitioner in these duties and sometimes in giving clinical evidence, and why? Because they have sworn to obey the ninth tenet of the London County Council's "Rules *re* Appointment of Coroners," which see—in difficult cases, by employing a special pathologist and (tenet 8) in holding inquests with or without *post mortem examinations* in certain other cases, a grave injustice to those in general work

As things went on in this case (judging from the report in THE LANCET) the evidence was inadequate on the part of the mother and of the medical man Of the mother, in that nothing was asked as to recent personal history of the boy, as to length of cough, malaise, appetite, chills, colic, headache, squint, or previous sickness, of the medical man as to temperature, history of cough, heat of skin, urine, dulness, crepitation, bronchial breathing, or other physical states, in fact, the use of the word "blow" (in the absence of evidence) seems to have lighted a bonfire which extinguished the course of further inquiry and to have led to an unprofessional theorem Now, no lawyer-coroner is competent to discuss clinical phenomena let alone the rôle of pathological states, in my opinion, and as forensic *versus* clinical cases at inquests occur in the proportion of 15 to 100 the comparative eligibility of lawyers and medical men for the office of coroner goes without saying surely pathology stands before logic and torts in the matter of sudden deaths.

No wonder, then, when law unfolds medicine that a verdict reads as a chimera—"a shot in the dark"—a travesty. With the symptoms of vomiting, abdominal pain, and irregular pupils, although it is not the duty of the medical witness to theorise, there was an opportunity of ventilating a differential *diagnosis and this would* have won over by assisting the coroner, whose respect we should always manfully court [illegible] have been [illegible] monia, severe and sudden (but here there would s ill be many cardinal symptoms to spot even at the eleventh hour), More history, an examination of the urine, sputum, &c, would have greatly helped, but is it not likely that the boy had an empty stomach, was overwrought by lessons, play, and a latent disease, and then was stricken by a meningeal *effusion paralysing the third nerve of* the dilated pupil side, all of which was due to an unrecognised influenza? The play of the pupils to light was not mentioned Mr Kennard may congratulate himself that he was subpœnaed for clinical evidence as some of us do not get that Lastly, I should like to mention that I always make it a point to have another professional friend to help me in any post-mortem examination I am, Sirs, yours faithfully,

M D, M.R C S

May 15th, 1905

LIVINGSTONE COLLEGE

THE principal of Livingstone College at Leyton, E, has issued an illustrated pamphlet describing the work of the college which has now been established for nearly 12 years May 23rd is commemoration day, when all who are interested in the college are invited to attend As it is the only institution in the world specially devoted to the training of missionaries in the elements of medicine and surgery the pamphlets above alluded to make a very interesting souvenir. There can be no doubt of the good work which the college does for missionaries going to unhealthy climates or to isolated posts and the institution, therefore, ought to receive the financial aid of which it is greatly in need At present there is an accumulated deficiency of over £600 and it would be most inexpedient to raise the fees A friend of the college has offered £200 provided £1000 can be raised by commemoration day (May 23rd) and £550 of this sum is still required We trust that the required sum of money may reach the treasurer, Mr R L Barclay, 54, Lombard street London, E C, before the date mentioned.

PRESENCE OF MIND IN A SMALL CHILD

THE following instance of presence of mind in a small child, aged six years, was recently brought to our attention. The little girl's father while examining a gas leakage broke off the bracket and accidentally ignited the gas, with the result that a long flame shot up towards the ceiling. No damage was done, as the gas was at once turned off at the meter, but shortly afterwards it was discovered that the little girl was missing from the house. Then a fire-engine arrived and it was found that unknown to anyone, and upon her own initiative, she had left the house and given the alarm at the fire station, a distance of several hundreds of yards away. To medical men this kind of readiness in small children to grasp a situation is important, because children, even mites of six years of age, are so often left in charge of infants. As it happened there was someone in the house to turn off the gas at the meter and possibly to punish the child for officiousness, but in other circumstances such promptitude might have saved life and property.

COMPULSORY SCHOOL ATTENDANCE AND PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—I had so many complaints in Shropshire that the Education Act, as it was administered, was unnecessarily harsh and unfair to the working classes, because it was assumed that if a child was too ill to attend school its parents must pay about 2*s.* 6*d.* for a doctor's certificate or be summoned and fined that I did my best to find out what the law really was. I also gave two cases in all the local papers which had come to my knowledge where the poverty of the parents had practically compelled them to send a sick child to school and in each case had resulted in the death of the child, but the cases would take up too much of your valuable space. It appears that it is not correct to suppose that a parent is obliged to get a doctor's certificate when a child is not well enough to go to school. It rests entirely with the school attendance committee to decide on the merits of each case whether it will send a particular case to be prosecuted before a magistrate or not. The school attendance committees cannot, of course, grant a legal exemption but they can do what comes to exactly the same thing. They can refrain, when they think the circumstances justify it, from prosecuting parents for the non-attendance of a child, and it is their business to find out whether any case is genuine or not. The school attendance committees have discretion left to them in these matters and ought to use their discretion, because matters of this kind cannot be dealt with by a hard-and-fast law. Otherwise we might as well be under the iron heel of a Government department attempting to administer minute local matters from Whitehall. It would surely be extremely unjust if working people were obliged to pay for a doctor's certificate every time a child had a bad cold on his chest or some other ailment for which he might be reasonably and rightly kept from school. The fact appears to be that school attendance officers find it easier to make a hard-and-fast rule, as it saves them trouble. County councils have power to make a by-law to the effect that children between the ages of five and seven years of age need not be compelled to attend school if the nearest school is more than a mile from their home.

I am, Sirs, yours faithfully,

Shrewsbury, May 13th, 1905. ROWLAND HUNT.

ANOTHER PROPOSED CANCER REMEDY.

THE following letter was recently received by the house surgeon mentioned below. It will be seen that the plant, according to the writer of the letter, has a wide range of usefulness. We have not seen the plant but we should think that probably it belonged to the spurge family, the plants of which all contain acrid juices and if applied in the manner directed would cause ulceration; but eating the leaves of spurge would most likely be dangerous.

To the House Sergeon Brompton Hospital.

SIR,—Enclosed you will find a wild plant. It is a cure for anything (such as a sore). Would you mind trying it for a cancer, or anything of that kind. I have other plants, which I will send when I can get them to grow. Trusting you do not mind giving this a trail.

Yours truly,

Komgha, April 9th, 1905. ISABELLA REANEY.

Address, Mrs. I. Reaney, Komgha, Cape Colony, South Africa.

"Take the leaf and dip it in cocoanut oil to make it soft, and put it on the sore or cancer all day. At night put a little coarse meal, made soft by adding water. The next day put a leaf on again every day for three weeks. The leaf should draw the sore, and which causes terrible pain, until the cancer falls out, leaving a large hole, which is healed up by ointment. You can eat the leaves, which will do you a great deal of good, or you can put them in water and drink it. I don't think it is poisonous. The stems you boil them and drink. It will clear your blood from any disease."

VASENOL: A NEW FORM OF ADMINISTERING PETROLEUM.

THE difficulty that is met with in emulsifying vaseline and liquid paraffin has led to the addition of fatty acids, soaps, and other bodies but these have possessed therapeutic objections. According to the *Apotheker Zeitung* A. Kopp has overcome these difficulties by adding to the paraffin a small quantity of the higher fatty alcohols obtained from wool fat, spermaceti, or other sources. The term vasenol has been given to the various preparations of paraffin when treated in this way; they have interesting pharmaceutical and therapeutic properties. They mix readily with aqueous liquids, producing emulsions which are quite neutral, and when applied locally in this form medicaments are stated to be absorbed in a higher degree than when mixed with soft paraffin alone. Vasenol, an emulsion of soft paraffin with 25 per cent. of water, has the consistence of an ointment; it can absorb several times its weight of water and can be mixed with a great number of fats, salts, powders, extracts, and liquids. Liquid paraffin mixed by this method with 33 per cent. of water forms a neutral oil possessing similar properties; thus, it may be used for liniments, or it may be mixed with water in any proportions and used as an injection. It is useful also for soaking tampons in gynæcological practice. Vasenol may be produced in the form of a powder containing 10 per cent. of vasenol. This preparation combines the properties of an absorbent powder with those of vaseline and maintains the skin in a state of suppleness. It may be used with advantage in dressing wounds, as various astringent and antiseptic substances may be added.

A LARGE INFANT.

To the Editors of THE LANCET.

SIRS,—A few months ago you published notes, sent to you by Mr. R. E. W. Jennings, of a large infant weighing 13 pounds. I beg to inform you that I delivered a Dutch lady of a son weighing exactly 14¼ pounds. The child to me looked as if he would be more satisfied with a chop than a drink of milk from the breast. I also attended the same lady at a previous confinement when she gave birth to a son weighing 14½ pounds. Both confinements were perfectly natural and quick, forceps not being necessary in either case. I may mention that both mother and father are large persons.

I am, Sirs, yours faithfully,

WM. P. JOHNSTONE, M.B., C.M. Edin., J.P.

Maraisburg, near Johannesburg, April 20th, 1905.

◆

Disgusted.—If our correspondent can prove his statement that his patients have been approached by touts pressing them to join the "family club" the matter is one which should be laid before the General Medical Council. The Council would, of course, require the strictest proof before acting, but if it was satisfied that such an abuse of practice had occurred it would probably take severe measures.

Old-fashioned has not understood our answer, nor is he aware of the details of the case. Medical men can never be too strict or too altruistic in their professional relations towards each other but we are unable to support the view that a medical man has a property in his patient and that the patient cannot change his medical adviser if he wishes.

G. W. (Birmingham).—The police are compelled to make inquiries in what might be a case of murder the moment the circumstances come to their attention, so that the midnight call seems to us justifiable. Our correspondent might consult a solicitor as to the possibility of recovering a fee; we do not see why he should be disturbed for nothing.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private informa- [illegible] *d addresses of* [illegible]

We [illegible]

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		*TO THE COLONIES AND ABROAD.*	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Westminster Gazette, Yorkshire Mercury, Daily Chronicle, Irish Times, Surrey Advertiser, Reading Mercury, Literary Digest (New York), Scientific American, Daily News, Australasian Medical Gazette, Western Mail (Cardiff), Herefordshire Mercury, Windsor and Eton Express, Halifax Courier, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. R. Ackrill, Harrogate; Messrs. Allen and Hanburys, Lond.; Apollinaris Co., Lond.; Mr. R. J. Albery, Lond.; Mr. Algernon E. Aspinall, Lond.; Dr. H. G [illegible] Hubert [illegible] Atlantic [illegible] Havana; A. M. R.; Mr. J. Fenwick Allen, Whalley Range.

B.—Mr. A. E. Barrett, Lond.; Mr. A. A. Bradburne, Southport; Dr. Hugh W. Bayly, Lond.; British Lysoform Co., Lond.; Mr. Harold Barwell, Lond.; Dr. R. Blondel, Paris; Birmingham, Medical Officer of Health of; Birmingham, Public Analyst of; Mr. O. Berthier, Paris; Mr. C. Birchall, Liverpool; Mr. F. Boehm, Lond.; Staff-Surgeon R. F. Bate, R.N., Lond.; Bristol City and County Lunatic Asylum, Visiting Committee of; Dr. A. G. Bateman, Lond.; Mr. W. H. Brown, Leeds.

C.—Dr. C. J. Cullingworth, Lond.; Mr. C. J. Clay, Lond.; Messrs. Coverley and Westray, Lond.; Messrs. T. Christy and Co., Lond.; C. E. W.; Dr. P. M. Cambridge, Freeburg, U.S.A.; Clinic Publishing Co., Chicago; *Chester Courant*, Manager of; Messrs. Cassell and Co., Lond.; Clinical Society of London, Secretary of; Mr. Louis Calvert, Lond.

D.—Mr. E. Demalde, Piacenza; [illegible] Lond.; [illegible] Medical [illegible] Captain T. H. Delanv, I.M.S., Dublin; David Lewis Northern Hospital, Liverpool, Secretary of; Denver Chemical Manufacturing Co., Lond.; Mr. R. C. Dun, Liverpool.

E.—Messrs. Evans, Sons, Lescher, and Webb, Lond.; Dr. Ch. Esmonet, Paris.

F.—Mr. L. Fishon, Paris; Fine Art Society, Lond.; Dr. Herbert French, Lond.

G.—Mr. F. W. Gamble, Lond.; Dr. A. Knyvett Gordon, Newton Heath; Guest Hospital, Dudley, Secretary of; Messrs. W. Green and Sons, Edinburgh; General Life Assurance Co., Lond., Secretary of; Mr. E. Godfray, St. Martin's, Jersey.

H.—Dr. S. H. Habershon, Lond.; Messrs. Hollebone and Co., Lond.; Messrs. Hope and Sons, Lond.; Mr. Rowland Hunt, Lond.; Mr. F. S. D. Hogg, Rickmansworth; Hospital for Sick Children, Lond., Secretary of; Hull Royal Infirmary, Secretary of; Hotel Redcliffe, Paignton, Manageress of; Homes for Inebriates Association, Lond.; Dr. W. R. Huggard, Davos Platz; Mr. J. T. Hereford, Hereford.

I.—Irish Medical Association, Dublin, Editor and Hon. Secretary of; Imperial Accident Assurance Co., Lond.

J.—Mr. W. R. W. James, Lond.; Mr. Richard Jennings, Grays; J. T. P.; Miss Emma V. Jones, Valparaiso, Ind., U.S.A.

K.—Mr. Joseph Keen, Folkestone; Dr. Kesteloot, Ostend; Messrs. R. A. Knight and Co., Lond.

L.—Mr. H. K. Lewis, Lond.; Mr. F. W. Lowndes, Liverpool; Messrs. Lalonde Bros., and Parham, Weston-super-Mare; Mr. J. G. Leigh, Lond.

M.—Mr. W. Martindale, Lond.; Maltine Manufacturing Co., Lond.; Mr. R. Mosse, Berlin; Major D. E. Marshall, I.M.S., Edinburgh; Manchester Hospital for Consumption, Secretary of; Professor Howard Marsh, Lond.; Messrs. J. Mavthorn and Son, Biggleswade; Mr. C. A. Moore, Lond.; Mrs. McConaghy, Lond.; Dr. J. A. MacDougall, Cannes; Dr. C. F. Marshall, Edgbaston; Metropolitan Convalescent Institution, Secretary of; Metropolitan Board of Water Supply and Sewerage, Sydney, Secretary of; M.D., M.R.C.S.; Messrs. Mayer and Meltzer, Lond.; Dr. J. C. McVail, Glasgow.

N.—Dr. A. E. Neale, Lond.; Mr. Sheffield Neave, Khartoum; National Sanatorium for Consumption, Bournemouth; New Engine Co., Acton; Nottingham General Hospital, Secretary of; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

O.—Dr. T. S. A. Orr, Crail.

P.—Mr. Y. J. Pentland, Edinburgh; Mr. J. Palmer, Liverpool; Dr. Percy Pope, Lond.; Mr. H. Potter, Lond.; Mr. A. Perry, Lond.; Dr. W. Pasteur, Lond.; Dr. Bedford Pierce, York; Mrs. Potter, Rathmines; Mr. Thomas Power, Lond.; Mr. F. A. Pond, Liverpool.

Q.—Queensland Public Health Department, Brisbane, Secretary of; Queensland Government Statistician.

R.—Mr. John A. Randolph, Lond.; Dr. S. H. Robinson, Londonderry; Mr. A. R. Roche, Lond.; Royal Mail Steam Packet Co., Lond., Chairman of; Messrs. Rippon, Boswell, and Whitaker, Exeter; Messrs. Rebman, Lond.; Dr. A. E. Russell, Lond.; Rita; Messrs. Reynolds and Branson, Leeds; Messrs. Robertson and Scott, Edinburgh; Royal Waterloo Hospital for Children and Women, Lond., Secretary of; Royal Meteorological Society, Lond., Assistant Secretary of.

S.—Mr. J. H. Stennett, Byfield; Mr. C. M. Spencer, Southerndown; Stone House, Canterbury, Medical Superintendent of; Society for the Study of Disease in Children, Lond., Secretary of; Mr. W. R. H. Stewart, Lond.; Society of Apothecaries of London, Master and Wardens of; Mr. J. E. Stroschein, Berlin; Mr. C. St. Aubyn-Farrer, Lond.; Dr. J. Pollock Simpson, Lond.; Society of Arts, Lond., Secretary of; Mr. Andrew Stewart, Birkenhead; Mr. F. A. An Address

ENTITLED

CLINICAL ILLUSTRATIONS OF ANGINA PECTORIS AND PSEUD-ANGINA.

Delivered before the Brighton and Sussex Medico-Chirurgical Society on April 6th, 1905.

BY SIR W. H. BROADBENT, BART., M.D. LOND., D.SC. LEEDS, F.R.S.,

PHYSICIAN IN ORDINARY TO HIS MAJESTY THE KING AND TO HIS ROYAL HIGHNESS THE PRINCE OF WALES.

GENTLEMEN,—It is not necessary that I should describe angina pectoris in all its varieties. We understand by it pain in the cardiac region, chiefly behind the sternum, with radiation, most frequently down the inner aspect of the left arm to the elbow, or to the hand, especially the two ulnar fingers, or down both arms, or to the shoulder, neck, or face. Or it may begin in some part of the arm, as, for example, by painful tight feeling round the wrist, extending up the limb to the chest. The pain may vary in character and intensity and may be described as crushing by a gigantic weight, or as if the chest were held in a vice, or as tearing, or burning. All sufferers agree that there is no other pain like it and it is usually accompanied by a sense of impending death. The distinctive characteristic of true angina is that it is induced by exertion, by walking upstairs or up an incline, or against the wind, more easily soon after food (after breakfast is a favourite time in early cases), or when the air is cold on first going out. Or an attack may come on when the patient goes to bed, after perhaps walking upstairs, the exertion of undressing, assuming the horizontal position, and the contact of cold sheets. Next to exertion in provoking an attack comes excitement, and in advanced cases the movement of a limb, a breath of air, the slamming of a door, the announcement of a visitor, may be sufficient to precipitate an attack. The effect on the circulation common to all these exciting causes is increase of the blood pressure in the arterial system and this must be regarded as the determining antecedent. The attacks are usually brief, the sufferer, indeed, will often say that if they had lasted another minute he must have died, he stands still, or suspends any exertion in which he is engaged, and may not even dare to breathe. With the cessation of the exertion the paroxysm subsides or speedy relief may be obtained by inhaling amyl nitrite or taking nitro-glycerine. The patient may then be able to resume his walk and to go on for some time without provoking another attack. Sooner or later sudden death usually occurs during, or at the outset of, a paroxysm. While the attacks are, as a rule, soon over, the pain may last for hours. In one case to which I was called the patient had spent an entire night sitting in a chair, not daring to move, the face bathed in cold perspiration and having an agonised expression. He made a temporary recovery. In another, in which I made a post-mortem examination and found the heart in an advanced state of fatty degeneration with calcified coronary arteries, death took place after hours of terrible suffering in the night.

During the paroxysms the one condition of the circulation which seems to be always present is contraction of the peripheral arterioles. It was the recognition of this fact and of its significance which formed the basis of Sir Lauder Brunton's employment of amyl nitrite and nitro-glycerine, which have been of such value in the treatment of angina. I have sometimes been tempted to think that in certain cases the initial event is that the blood-supply from the heart fails and the arteries contract down upon the empty lumen as they do post mortem. The pulse may remain steady or become irregular, it [illegible] may be *slow and hesitant.* [illegible] its natural colour. [illegible] found has been more or less occlusion of the coronary arteries from a calcareous or atheromatous or sclerosed condition of these vessels with perhaps thrombosis, or from disease of the walls of the aorta narrowing their orifices. As a consequence of the obstruction to the blood-supply, general or local degeneration, fatty or more frequently fibroid, of the walls of the heart is usually produced, though death may occur before even microscopic changes in the muscular striæ can be recognised. A noteworthy fact is that the cavities are almost always found to be empty after death.

The theories, as they may be called, or explanations advanced as to the cause of the pain are very many in number. Huchard enumerates no less than 80 of these hypotheses. I shall consider them simply in so far as they concern prognosis and treatment and from this point of view only two demand serious attention. Huchard regards the attacks as consisting essentially of what may be called cramp of the cardiac muscle due to ischæmia or privation of blood produced primarily by disease of the coronary arteries or occlusion of their mouths, possibly intensified by spasmodic contraction of these vessels. For Huchard there is only one true angina pectoris, the coronary, and his discussion of the entire question is one of the most interesting parts of his monumental work. An alternative view is that the pain is due to overstrain of the heart in the endeavour to overcome resistance in the peripheral circulation to which it is no longer equal or to distensive stress of the aorta. The incompetence of the heart may be the result of inherent weakness from degeneration of its muscular walls, or may be only relative to great increase of the resistance in the arterioles and capillaries, or may be attributable to a combination of the two. Some degeneration or deterioration of the heart walls must, however, be an indispensable, and, indeed, the special, factor in the causation or angina would be much more common in chronic Bright's disease in which arterial tension reaches its maximum. The inadequate blood-supply, again, which gives rise to the degeneration may also affect the nutrition of the cardiac ganglia and nerves and in this way predispose to pain. The conclusion that the condition of the heart walls must be the dominant factor in angina seems to me to be confirmed by two cases which have come under my observation, in which, after plague, the heart was left in a state of extreme asthenia and pain of an anginoid character was experienced on very slight exertion.

Before entering upon the consideration of the different forms of true angina we may speak of false angina. To establish this distinction will be a matter of vital importance, as it may enable us to lift the burden of constant apprehension from the minds and lives of patients and to restore a family to tranquillity and happiness. We may dismiss the hysterical person, male or female, who comes with a diagnosis of angina pectoris ready-made and cannot find terms adequately to describe his or her complicated agonies, who is ready to adopt any suggestion we may make as to the seat and character of the pain and as to the direction and extent of its radiation. The attacks may come on at any convenient time and may last indefinitely but are not allowed to interfere with pleasant engagements. These patients do not wish their friends to be undeceived as to the character of the attacks.

Paroxysmal pain in the cardiac region may be due to a great variety of conditions; it would be waste of time even to enumerate them. Speaking generally, in all cases in which the attacks come on chiefly during repose, when perhaps the patient is sitting reading or writing, however severe and however closely they may appear to conform in the description given of them to true angina, the presumption is that they are spurious unless they have been led up to by the frequent occurrence of pain induced by exertion. The presumption is increased if there are tumultuous action of the heart and irregularity or intermission of the [illegible] conscious, particularly if [illegible] same may be said of car[illegible] if there is no history of the patient having also been brought up short when walking by pain in the chest. If the nocturnal attacks recur, and particularly if they observe a sort of punctuality in their recurrence, it may be concluded that they are of gastric origin. We shall, however, be cautious in coming to this conclusion and in acquitting them of all serious significance if there is valvular disease of the heart or considerable dilatation. The cases which most closely simulate true angina are those in which there is dilatation of the stomach and when, with a dilated stomach, there is high arterial tension, which is so very

No. 4265.

frequently associated with angina, we may have attacks which can scarcely be distinguished from those of true angina. I have chosen three of these as illustrations. In all of them a diagnosis of angina had been made.

CASE 1. *Pseud-angina.*—A retired officer, aged 70 years, consulted me in October, 1895. He said he had suffered from heartburn for 30 years and had had four attacks of influenza which had left his heart weak, so that after a walk of a quarter of a mile he was pulled up by pain in the centre of the chest which radiated down to the hands on both sides. During the attack his breathing was embarrassed and there was palpitation of the heart. He often had to lie flat on the floor. He was also liable to attacks which came on at 3 A.M. in which there was a sense of suffocation as well as severe pain and violent palpitation. He took carbonate of sodium and magnesium, brought up gas, and was then able to sleep again. The pulse was large and very tense. The cardiac impulse was weak and the apex beat could not be defined. The sounds were normal. The abdomen was very prominent; the stomach resonance was extensive, coming up to the fifth space. Voluminous splashing could be elicited. The diurnal attacks were extremely like those of true angina and they were induced by slight exertion. I have, however, never known a patient to lie flat in angina and it is very unusual for him to complain of palpitation. The attacks coming on punctually at 3 A.M. were certainly attributable to the dilated stomach and it seemed possible that this played an important part in the production of the anginoid paroxysms which followed slight exertion. He was dieted, was given pilula hydrargyri and ipecac and rhubarb, with the idea mainly of reducing the pulse tension, and bicarbonate and sulphocarbolate of sodium with ammonia, gentian, and peppermint for the relief of the distension of the stomach. Ten days later he had only had one attack during which the pulse was irregular—hurried and stopping in turn. A serious indiscretion in diet was followed by distressing symptoms of a mixed character, but in December he was apparently well in all respects. I have met him since in society, sometimes very late at night. He has always said that he was perfectly well. Since the above was written he has called upon me looking the picture of health and enjoying life in all its aspects notwithstanding his 80 years.

CASE 2. *Vaso-motor pseud-angina.*—A man of spare habit had suffered from some affection of the heart for several years. It was said to be angina and he had twice undergone a Nauheim course. The pain was brought on by exertion, especially after food; its seat was across the upper part of the chest and down the left arm to the elbow; it was not very severe and the liability to paroxysms varied greatly. When I saw him on Nov. 9th, 1903, the pulse was somewhat tense; the dimensions and sounds of the heart were normal, but a curious dry vibratory friction was heard over the apex, especially during expiration. It resembled the sound produced by a wet finger on a pane of glass and was exaggerated when he lay down. He had been taking iodide of potassium and I attributed the friction to deficient moisture of the pericardial surfaces due to the iodide. The stomach resonance was extensive and the upper line was unduly high. Splashing was very distinct and voluminous; there was much dreaming and he awoke early. The tongue had a slight central fur. The treatment was suggested by the condition of the stomach and was practically such as that described. The patient was very soon able to walk uphill between 12 and 1, when the stomach was comparatively empty, but still had pain on exercise after food. On Nov. 30th the pulse was soft and elastic, the apex beat was felt in the normal situation, and the heart sounds and intervals were normal. He thought a tonic pill which I had prescribed did not suit him and took again a mixture containing iodide. When next seen, on Dec. 14th, a creaking pleural friction was heard over the lower part of both lungs. The dilatation of the stomach persisted and much splashing was elicited by succussion. Sodium sulphocarbolate and carbonate were now given with ammonia and gentian three times a day. With the suspension of the iodide the pleural and pericardial friction disappeared. There was distinct general improvement but with great fluctuations which were usually traceable to errors in diet. I found, for instance, that while drinking little with his meals in accordance with my instructions he took a breakfast cup of weak tea immediately after lunch. He was also eating stewed prunes and Normandy pippins after telling me that apples in any form disagreed with him. The condition of the stomach was not much modified and it was difficult, as the patient was only seen at uncertain intervals, to control the eccentricities in the way of food. He was therefore taught to wash out the stomach and for six weeks did this every night. I did not see him for three months, when he could take a good deal of exercise without pain and had resumed his morning ride. When last seen, on Jan. 25th, 1905, he had remained well, though the washing out of the stomach had been given up for about six months. On the previous Sunday he had walked two miles to church and had read the lessons. He has since had occasion to write on other matters and spoke of his restoration to health.

CASE 3. *Pseud-angina.*—A man, aged about 60 years, consulted me in September, 1903, on account of pain across the chest to the left shoulder and down the arm, coming on after exertion but also at other times. He was conscious of beating of the heart and said he heard it. The pain had been pronounced to be angina and work and exercise had been forbidden. He suffered also from giddy feelings as if tipsy. The pulse was rather tense; the heart sounds and intervals were normal, the aortic second sound being slightly accentuated. The stomach resonance was found to be extensive and its upper limit high in the chest. The diet was regulated. A mild mercurial aperient was given twice a week and measures were taken for the reduction of the distension and dilatation of the stomach. The restrictions on exercise and professional duties were gradually relaxed and removed. Recurrences of some or other of his symptoms brought this patient to me from time to time. The pulse after the first visit was of normal tension; the apex beat was normal in character and in situation; the aortic second sound was scarcely accentuated. The dilated condition of the stomach persisted more or less and it was found necessary to have repeated recourse to the treatment for dilatation of the stomach which I have described. I have seen him within the last few days. His duties had involved frequent journeys and much and varied work. He had shot well through the winter and walked 11 miles with enjoyment. He expressed himself as feeling perfectly well and capable of any amount of exercise, always feeling the better for it. He had pain in the cardiac region from time to time but it had no relation to exertion and could usually be traced to irregular meals or unsuitable food.

Coming now to true angina, the diagnostic distinction is that the attacks of pain are brought on by exertion. The first paroxysm may come on during some special effort and may be very severe. More commonly the early attacks are slight. Angina, answering to this criterion, is met with clinically in association with aortic valvular disease, or with aortitis, or with dilatation of the aorta, general or aneurysmal, or with atheromatous disease of the aorta without obvious dilatation, or with fatty degeneration of the heart. These may be represented as different stages or different effects of general disease of the arterial system and all of them, except perhaps acute aortitis, are very common without angina. Angina is established when the coronary arteries are implicated. Disease of the mitral valve does not give rise to angina; the supervention of mitral regurgitation may, indeed, greatly diminish the liability to attacks in a case of angina. This may perhaps be because breathlessness on slight exertion anticipates the paroxysm of pain; the course of the disease may be entirely changed. In connexion with valvular affections it is only in aortic disease that angina is met with and then not when the insufficiency or obstruction is the result of rheumatic valvulitis. Very frequently, indeed, a systolic murmur in a case of angina does not indicate real obstruction and, with a diastolic murmur, there may be extremely little regurgitation. When this is the case the valvular affection, as such, is of no importance in itself; it is simply an effect of roughness or rigidity of the ring and cusps or of dilatation of the orifice and of the root of the aorta, due to atheromatous disease in the immediate neighbourhood of the coronary arteries which has narrowed their mouths or invaded their walls. The valvular affection and the dilated and atheromatous condition of the aorta are themselves effects of old-standing high arterial tension and the aortic second sound will be loud and ringing even when there is a double murmur, or the changes in the aorta and valves and blocking of the coronary arteries may be due to syphilitic disease of the arterial system, which is not necessarily attended with high blood pressure.

The atheromatous changes in the aorta, while ultimately exhibiting extreme forms of degeneration such as calcareous patches begin originally as inflammatory exudations. The inflammation however, is so insidious and chronic that no clinical evidence of its progress is recognisable except that its presence may be inferred when physical signs of dilatation of the ascending aorta or of the arch can be made out. Occasionally subacute aortitis reveals itself by symptoms.

CASE 4.—In November 1899, a man, aged 50 years, who had previously been under my care for various ailments, came to consult me, looking ill and complaining of pain in the chest. He had a spasmodic cough and his voice was cracked, the left pulse was smaller than the right. These symptoms were highly suggestive of aneurysm but no confirmatory physical signs were obtainable. A loud systolic aortic murmur not previously present, was heard over the entire heart. The maximum intensity was at the right second space but it was reinforced along the course of the aorta. The aortic second sound was not accentuated. This patient remained under observation for some months. He refused to believe that there was anything serious the matter with him and could not be persuaded to rest. The course of the case was extremely erratic. The pain in the chest varied in degree but could never be called severely anginoid. From time to time he looked fagged and worn and his eyes were sunken. His nights were often bad and disturbed by the beating of the heart. The pulse was never tense and was usually below the normal frequency (60 54) sometimes small and weak at others large and lax. The difference between the right and left radials did not last. Soon after I first saw him a soft diastolic murmur was developed. It was sometimes audible at others not, but at length it disappeared. All symptoms subsided in about six months but he was left with a loud systolic murmur and a sharp second sound suggestive of thin parchment like aortic walls. The patient is still actively engaged in business. There can be no doubt that there was inflammation along the whole course of the arch of the aorta. The orifice of the left subclavian was at first apparently narrowed by swelling of the tunica intima. Fortunately the coronaries were not implicated.

In acute aortitis, which is very rare, there may be frequent anginoid attacks while the patient is lying in bed without any apparent exciting cause if the mouths of the coronary arteries are blocked by the swelling of the internal tunic of the aorta. A case has occurred very opportunely in the out patient practice of my son which will be related.[1] In a large proportion of the cases of angina the condition known as arterio sclerosis is present in a marked degree. The radials are not only full between the beats of the pulse but the coats are thickened and firm the vessels are tortuous and can be rolled under the finger and followed up the forearm. The radials and the brachials at the bend of the elbow can often be seen to be thrown into curves with each pulsation. The aorta is dilated. It is not always easy to make this out by percussion but it is indicated very distinctly by the loud, low pitched sometimes ringing aortic second sound heard for a considerable distance outside the right border of the sternum and across the manubrium. In some cases the maximum intensity is shifted from the second to the third space by elongation of the ascending aorta carrying the base of the heart downwards. Occasionally a slight tracheal tug can be felt.[2] The angina, however does not stand in any direct relation with the degree of dilatation of the aorta but is dependent on interference with the coronary circulation. Angina may supervene in a comparatively early stage of the general arterial disease before the radials are much thickened or distinctly tortuous and before the aorta has become dilated if the coronaries happen to be involved in a swollen patch of exudation from the first. In syphilitic disease of the arterial system, while there may be valvular lesions dilatation of the aorta, or aneurysm the blood pressure may not be high. It is the part played by high blood pressure or high arterial tension in angina which affords us an opening for treatment which may alleviate and sometimes cure. The cases in which the prognosis is most unfavourable and in which we can do least for the relief of the patient are those in which the physical signs are negative. This is particularly the case in fatty degeneration of the heart. In a less degree the remark is applicable to the cases in which, with angina there are little thickening of the radials and little dilatation of the aorta in consequence of premature implication of the coronary arteries.

The treatment of angina, then, resolves itself into the treatment of high arterial tension. The resistance in the peripheral circulation which gives rise to this I place primarily in the capillaries and it is attributable to the presence in the blood of impurities which provoke this resistance. The object before us then, is to prevent the formation and to promote the elimination of these toxins. We simplify the diet, reducing the amount of animal food, and especially of the richer meats, bearing in mind also the fact, pointed out by Dr G Oliver, that boiled meat raises the arterial tension much less than roast meat. Meat extracts of all kinds will be forbidden. It may be worth while in some cases to order a strict milk diet and to enforce absolute rest. The patient must, of course, be placed under the best obtainable hygienic conditions as regards air and climate and should take daily such exercise as he is capable of without bringing on pain. Exercise may be supplemented by judicious massage and resisted movements. By way of promoting elimination a tumbler of water should be drunk night and morning hot or cold—perhaps also an hour before meals. The alkaline salts also are eliminants, particularly the potassium and lithium salts and may be given to aid the action of the water. Certain mineral waters are useful in this respect. A more definite effect on arterial tension is obtained by mercurial aperients and iodides presumably through their eliminant action possibly also through their influence on metabolism. Most striking reduction of arterial tension follows the administration of a single grain of calomel pilula hydrargyri, or hydrargyrum cum creta nightly or every second or third night, with just sufficient of one or other of the vegetable or saline aperients to secure an efficient action of the bowels. Colchicum or ipecacuanha seems to enhance the vaso dilating effect. The iodides in addition to lowering the tension by promoting elimination may have some resolvent effect on the chronic aortitis which impairs the elasticity of the aorta and blocks the mouths of the coronary arteries.

The mild mercurial aperients and the iodides, then form the basis of the medicinal treatment of the cardio vascular condition which gives rise to angina. With them will be associated tonics or other remedies which may be indicated by functional derangement of any kind. Quite the most important of these is dyspepsia with flatulent distension of the stomach. The direct vascular relaxants, amyl nitrite and nitro glycerine, are invaluable for the relief of the paroxysms but their influence on the blood pressure is far too brief to have any beneficial effect on the arterial tension. The nitrites and erythrol tetranitrate have a more persistent vaso dilator effect and seem in some cases to aid materially in diminishing the frequency and severity of the paroxysms. A medical friend to whom I recommended the erythrol attributed to it immunity from attacks which he enjoyed for many years. A single recent case of aortic stenosis and insufficiency may be related.

CASE 5.—An officer aged 31 years consulted me on Nov 9th 1904 on account of pain on exertion or change of temperature beginning in the left elbow, shooting up to the neck and extending to the cardiac region. He might have this pain on waking from a dream in the early morning. He presented all the physical signs of combined aortic insufficiency and stenosis. The pulse was visible but full between the beats and not collapsing but bisferiens in character there were a distinct carotid throb great hypertrophy and dilatation of the left ventricle reduplication of the first sound in the apex region which could be felt as well as heard, loud double aortic murmur the diastolic murmur being conducted down the sternum rather than towards the apex and entire absence of the aortic second sound. The history was remarkable. He had never had rheumatism or syphilis or fever. He had served six years in India and five in South Africa and was in Ladysmith during the siege. The pain came on some time afterwards 18 months before he consulted me and at first was severe at night after a hard day's work and was gone in the morning. It had only assumed the characteristic features of angina after his return to England in March, 1904. He looked old and battered. His complexion was sallow with red patches. As he sat the head could be seen to move with each heart beat and the crossed leg was kicked forwards.

The first two cases of angina without valvular lesion are brought together as contrasts. In one a sudden fatal termination took place before any considerable change could be recognised in the aorta, illustrating early implication of the coronary arteries; in the other the aorta was enormously dilated and angina had existed for years without proving fatal.

---

[1] is case is published in our present issue p 1412.—Ed L.

[2] I was at one time disposed to speak of this class of angina as vasomotor in contradistinction to angina from fatty degeneration of the heart but the term is employed by various writers in a different sense.

CASE 6.—A woman, aged about 60 years, whom I had seen from time to time from 1892 for gouty pain and who had well-marked Heberden's nodules, complained for the first time in July, 1896, of pain behind the sternum and down the left arm on going upstairs. She was particularly liable to this in the afternoon. She suffered from obstinate constipation and looked older than her years. The pulse was very tense, the apex beat and right ventricle impulse were powerful, and the sounds were loud, the aortic second being accentuated. Hydrargyrum cum cretâ with extractum colchici and pilula colocynthidis cum hyoscyamo were given two or three times a week and arsenic and strychnine after food. Two months later she was much better and rarely had pain. In December, all treatment having been given up, she got up from her chair one afternoon and was walking across the room an hour after rather a large meal of minced chicken and mashed potatoes when she fell forwards dead.

CASE 7. *Angina; dilated aorta.*—A City man, aged 58 years, complained of gradually increasing pain in the cardiac region on exertion, shooting to the back and left shoulder and down the left arm. He has now to stop after walking 20 or 30 yards. The pain is more easily induced after food. He can lie down and has no pain lying or sitting. He had been compelled to give up business 18 months previously on account of the pain and had suffered from it for about five years altogether. Except that he was pale he did not look ill. The pulse was sudden, short, and unsustained, suggestive of aortic regurgitation; the artery was large and thin-walled, not emptying when the hand was raised. There was no visible carotid throb but the brachials were tortuous and visible at the bend of the elbow. No impulse or apex beat could be felt. The dimensions of the heart were not much altered but there was dulness for three quarters of an inch to the right of the upper sternum and here the second sound was loud and ringing with a musical tone. This second sound could be followed across the manubrium to the pulmonic area, showing that the aorta was dilated and thin-walled along the whole of the arch. The first sound was short; the tracheal breath sounds were conducted to the manubrium by the enlarged vessel but no tracheal tug was detected. A month later, after taking iodide of potassium (three grains), liquor arsenicalis (five minims), with tinctura cinchonæ composita and spiritus ætheris nitrosi, and resting more, he had much less pain but on exertion he had perfectly characteristic angina. The physical signs were the same but a slight tracheal tug could be felt and the left jugular vein was full and did not empty on deep inspiration so that the innominate of this side was compressed.

CASE 8. *Sudden death.*—An engineer, aged 57 years, was first seen in September, 1904. He had suffered from pain across the upper chest since August, at first while walking home after the day's work, which was hard and responsible, and more recently two or three times in the day. The pain did not shoot down the arm. The pulse was small and full between the beats; there was no apex beat or cardiac impulse but the dulness extended to the left of the normal limits. The first sound was weak, the aortic second accentuated and reinforced along the course of the arch. A slight tracheal tug could be felt. Rest and change were ordered; a mild mercurial aperient was given every other night or twice a week, as were small doses of potassium iodide. Erythrol tetranitrate was also ordered to be taken. Two months later, after giving up work and spending a month at Bournemouth, he was apparently better. He had intervals of three or four days between the attacks of pain and they often occurred between 3 and 6 A.M., beginning with a sensation in both hands, severe pain then extending across the upper chest and lasting two or three minutes. The right radial and carotid pulse was larger than the left and there was evidence of increased dilatation of the third part of the arch of the aorta, in dulness to the left of the manubrium and reinforcement of the aortic second sound here. It had also a lower pitch and a ringing character. A slight tracheal tug was recognisable. There was no impulse or apex beat. The treatment was continued on the same lines. A month later he died suddenly.

The following case is given to illustrate angina from syphilitic disease of the aorta. It was not dilated and the blood pressure was not high.

CASE 9.—A man, aged 59 years, consulted me in June, 1899, for pain which, according to his own account, was always latent in his left arm about the elbow and was roused by slight exertion and was then felt in the cardiac region and shot up the neck into the shoulder and down the arm. It had been very severe and brought him to a standstill when walking. The pulse was weak and unsustained though the artery was full between the beats. It varied in volume and force. The dimensions of the heart were normal; no impulse or apex beat could be felt; the sounds were weak, the first was short, and the aortic second was scarcely audible; there was an indistinct reduplication of the second sound over the right ventricle. He was a *bon vivant*, but before I saw him had been cut off smoking, coffee, and brandy. There was a history of syphilis. A blister had been applied and he had taken potassium iodide with strychnine and spartein. Benzo-naphthol had also been given for the relief of flatulence. The pain was less severe than it had been but he always ceased to walk when it came on. He looked well and had a good appetite; he slept well. The iodide was continued in five-grain doses with arsenic, ammonia and bark, and pilula hydrargyri (one grain) with pilula rhei composita and hyoscyamus was given twice a week. Nitro-glycerine tabloids were taken when the pain was severe. I saw him at long intervals. No change of note took place in the symptoms or physical signs. After a time slight albuminuria, which appeared fitfully at first, became permanent, the specific gravity of the urine being about 1014. I saw him last in December, 1902, by which time he was confined to his room and he died suddenly shortly afterwards.

The opinion has been entertained that the condition of the heart commonly found after death from angina was fatty degeneration in association with calcareous degeneration of the coronary arteries. It is only in a certain proportion of the cases, however, that there is the advanced degeneration in which the fingers sink into the softened walls and the heart almost falls to pieces by its own weight. The physical signs of fatty heart are chiefly negative. The dimensions are normal unless fatty change has supervened in a heart previously hypertrophied or dilated. No impulse or apex beat can be felt; the first sound is short and weak; the second, both aortic and pulmonic, is also very weak. The interval between the first and second sounds may be shortened, the ventricle not going through with its systole. The rate may be slow. All these conditions, except, perhaps, the approximation of the first and second sounds, may be present in cardiac asthenia, particularly if the heart is overlapped by the lungs. Sometimes a fairly good second sound is so masked when the lungs meet in the middle line that it is scarcely audible, but it will be heard in the carotids. We do not, therefore, make a hasty diagnosis of fatty heart. The pulse may be of great assistance. A sustained pulse at once negatives advanced fatty degeneration. On the other hand, calcareous degeneration of the radials or a thin inelastic condition of the arterial walls will be confirmatory of degeneration of the heart. Paralysis of the diaphragm will be evidence in the same direction. Fatty heart and fatty diaphragm not infrequently go together. It has seemed to me that the paroxysms last longer in fatty degeneration of the heart. The two cases mentioned of agonising pain going on through the night were examples of this condition.

CASE 10. *Angina.*—A medical man, aged 50 years, consulted me in June, 1898. He had gout at the age of 24 years and some years previously to my seeing him had suffered from asthma, for which he had been twice to Mont Dore. He had for some time been subject to a burning sensation in the upper cardiac region on ascending an incline, or going upstairs, or walking against a wind, which brought him to a standstill and caused him to burst into a cold perspiration. A sensation radiated down both arms. Nitro-glycerine gave instant relief. The pulse was small but not otherwise noteworthy; in particular it was not tense. The dimensions of the heart were normal; there was no impulse or apex beat. The aortic second sound was slightly accentuated. He went to Homburg and on his return was so much better that he resumed work and could walk six or seven miles. Going uphill, however, or facing a wind, excitement, nervousness, or night air, brought on pain which he described as an exaggerated heartburn over the sternum with neuralgic radiations down both arms. I saw him again on Nov. 7th as on the 6th, after a railway journey and eating sandwiches at 9 P.M., he had been seized at 4 A.M by extremely severe pain He had to get out of bed and kneel down and water ran out of his mouth. He had not his nitro glycerine at hand and the pain lasted one and a half hours, when he got a tabloid and was at once relieved. The physical signs were as before, the sounds perhaps weaker. After undressing a post systolic murmur of a frictional character was heard for a short time at the right second space which disappeared but was again reproduced on standing up Potassium iodide was now given with arsenic and nux vomica. I saw him for the last time in January, 1899 He had continued to attend more or less to his practice but had recently had a return of pain in the centre of the chest and down the arms on very slight exertion He had to rest after he got upstairs at night and again after taking off his drawers and socks, and he had had to stop two or three times between the Charing Cross Underground station and Northumberland avenue. He had pain after undressing in my room, during which the pulse, previously soft, became small and the artery was full between the beats He died the same night and the following instructive account of the final symptoms was sent to me by his partner —

> It appears that on his way home he was observed to be very ill by a fellow passenger who knew him and was so uncomfortable about him that he left his own compartment and went to the doctor's to see how he was [illegible]
> about his face a [illegible]
> would rather p[illegible]
> an attack of an [illegible]
> fact to his wife [illegible]
>
> [illegible] a further dose I persuaded him first to try the effect of hot stimulant—whisky, two ounces in hot water—hoping thereby to obtain vaso motor relaxation, but this, too, failed to ease him and I accordingly acquiesced in his demand for a further dose and gave him two minims more. This appeared to give some relief The paroxysms beca[illegible]
> fuller, and the [illegible]
> warmer and the [illegible]
> he was about to [illegible]
>
> [illegible] s wife—not
> [illegible] o inject as a
> [illegible] strychnine
> [illegible] y prolonged
> [illegible] hat he had
> [illegible] commenced
> [illegible] ectum His
> [illegible] rallied again
> [illegible] it soon after
> the pulse stopped finally

I have spoken of dilatation of the stomach as capable of giving rise to attacks closely simulating the paroxysms of true angina This condition may in cases of angina or of any serious heart disease precipitate the final event and be the immediate cause of a fatal issue Naturally, also, it may contribute to bring on attacks, as, indeed, may a hearty meal. In almost all cases angina is induced more readily by exercise soon after food This makes it very important that the upper limit of the gastric resonance should be carefully ascertained in all cases of angina

I have actually witnessed a death due to dilatation of the stomach I was asked to see a patient a short distance from town From the description of the case, which was clear and accurate in every detail, it was obviously one of true angina and probably of fatty heart The stomach was seen to be distended and in the course of the examination it had just been pointed out that the upper line of resonance corresponded with the fifth rib and the base of the ensiform when the patient became *slightly convulsed and unconscious and* died before our eyes.

CASE 11 —A man, aged 73½ years, was seized with pain in the chest and shortness of breath on his way to the City on Nov 28th, 1894, and turned aside to consult me. He had shot during the autumn and the first time he had any symptoms of the kind was not more than ten days previously, but from the 25th he had had pain, shortness of breath, and a sense of hollowness on walking each day. The dimensions and sounds of the heart were normal, the stomach resonance came very high and was extensive He went into the city against my advice and later in the day took a railway journey into the country. He died suddenly on going to bed that night after a heavy dinner

Lecture

ON

THE TREATMENT OF PUERPERAL INFECTION.

Delivered at the Medical Graduates' College and Polyclinic on March 8th, 1905,

BY FREDERICK J. McCANN, M D. EDIN., F R C S. ENG, M R C P LOND.,
PHYSICIAN TO IN PATIENTS SAMARITAN FREE HOSPITAL FOR WOMEN, LONDON

GENTLEMEN,—Nothing has so much retarded progress in the elucidation of the causation of the so called puerperal fever as the repeated attempts made to prove that it is a special disease differing from infection of wounds in other situations in the body This has also affected to a great extent the rational treatment of the disease, whether that treatment be prophylactic or curative

Childbed fever is wound fever due to the action of bacteria implanted in the wounds of the genital tract following delivery of the child No conditions could be more favourable for the spread of infection than those which obtain in the genital passages *after labour* There are wounds of the perineum of varying degree, wounds of the vagina, and wounds of the cervix. Added to these the interior of the uterus is a large, hollow wound lined by loose tissue in which the spaces are filled with blood and serum and at the placental site recent thrombi hang into the cavity. Further, the increased development of the lymphatic and vascular system of the uterus and the rapid changes occurring during the puerperium favour the spread of infection, whilst the proximity of that large lymph sac, the peritoneal cavity, constitutes a special danger.

Although there may not be large tears present in the cervix, vagina, or perineum after every labour there are innumerable small tears and fissures and surfaces from which the epithelium has been shed. If in addition the passages have been devitalised by long continued pressure or instrumental manipulation bacteria will grow and flourish in greater profusion The principal sites of infection are (1) the interior of the uterus, especially the placental area, (2) the cervix, and (3) the vagina and perineum The same organisms which produce infection of wounds in the body generally are found to be the cause of puerperal infection and they are (1) streptococci, (2) staphylococci, (3) *bacillus coli communis*; (4) gonococci, and various [illegible] organisms Krönig, examining 179 cases of [illegible] the following [illegible] eptococci and [illegible] al, 50 cases four due [illegible] 3 Sapræmia, 50 cases In 43 the organisms did not grow in the usual culture media, 32 of them being pure anaerobes

As in wound fever, so in childbed fever two principal varieties may be distinguished. (*a*) Wound intoxication, and (*b*) wound infection

(*a*) *Wound intoxication* —This is produced by organisms growing in dead matter (blood, wound secretions, necrosing placenta) During *their growth these organisms manufacture* certain poisonous substances which, when absorbed, cause a putrid intoxication, to which the term "sapræmia"

(Matthews Duncan) has been applied. Examples of wound intoxication are not uncommon in practice and are seen after abortion or full-time labour where portions of placenta or membrane retained in utero have become infected. The body temperature rises to 102° or 103° F., with or without a preceding rigor. The patient looks and feels ill; her pulse is rapid and she is drowsy, although natural sleep may be absent. There may be an icteric tinge in the skin, nausea or vomiting, and diarrhœa with offensive stools. The offending piece of dead tissue is removed and all may be well. If, however, the necrotic change in the interior of the uterus is widespread a condition is produced to which the term "putrid endometritis" is applied. Lining the interior of the uterus there is a well-marked layer of necrotic material, dirty greyish-green in colour, containing in its superficial portions various saprophytic organisms. Beneath the necrotic layer a well-marked layer of leucocytes exists, forming a granulation wall (nature's barrier) which prevents the further invasion of the saprophytes, protects the living tissues, and hastens the separation of the necrosed tissue.

Wound intoxication does not necessarily imply retention of necrosing tissue but may be caused by retention of the lochial discharge in utero—lochia metra; indeed, retention of the lochial discharge in utero is the commonest cause of one-day fever during childbed. The amount of retained discharge in utero may be considerable and in one case which I saw in consultation, after passing a dilator into the uterine cavity, a coffee cupful of pus was evacuated. Such retention is easily caused by a blood clot or piece of membrane obstructing the outflow of the discharge. Changes in the bladder and bowel, and even "getting up too soon," have been held to explain this retention.[1] The possibility of ante-partum infection of the liquor amnii where early rupture of the membranes has occurred must also be borne in mind. Occasionally gas-producing bacilli find their way into the uterus, producing the condition known as "tympania uteri."

(*b*) *Puerperal wound infection.*—Under this head are included the severe and frequently fatal examples of so-called "puerperal fever." The vast majority of such cases are due to streptococcal invasion, the streptococcus being the organism already well known to surgeons as the cause of erysipelas, phlegmon, pyæmia, and septicæmia. The following scheme serves to outline the methods of puerperal wound infection: 1. Local changes: infection of the wounds in the perineum, vagina, cervix, and of the endometrium. 2. Spread of the infection from the wounds: (*a*) by the blood-vessels producing thrombo-phlebitis, pyæmia, and septicæmia; and (*b*) by the lymphatics producing suppurative metritis (metritis dissecans), puerperal parametritis, perimetritis, and peritonitis.

Of the local changes the so-called puerperal ulcers are of importance. These ulcers are greyish-white in colour, vary in thickness, and are situated in the vulva, vagina, and cervix. Such ulcers have been misnamed "diphtheritic," but it must be remembered that the diphtheria bacillus plays no part in their causation, although this bacillus has now been proved to be one of the rarer causes of puerperal infection. These ulcers have the same structure as putrid endometritis, if allowance be made for the alteration in anatomical position—i.e., beneath the grey slough there also exists a granulation wall exerting a beneficent protective action. The rapidity in the growth of the streptococci is so marked that in a short time the whole genital tract becomes infected. If the original infection be situated in the cervix and endometrium the uterine discharge soon infects any wounds of the vagina and vulva, whereas infection of the vulva may be observed to have spread within 24 hours to the uterine cavity. The discharge from the "puerperal ulcers" is a small quantity of thin sero-pus until a well-marked granulation wall forms, when the discharge becomes more profuse and purulent in character. The more profuse the discharge of pus and the sooner it occurs the better the prognosis. When the uterine cavity is invaded a condition is produced to which the term "streptococcal or septic endometritis" is applied. Lining the cavity is a thin necrotic layer teeming with micro-organisms; beneath this an imperfect, small-cell infiltration layer (granulation wall), whilst micro-organisms permeate the muscular wall to the peritoneal coat, spreading along the lymphatics. When healing occurs the granulation layer becomes well developed, playing the part of an efficient filter. The infection may spread to the tubes and from occlusion of the abdominal ostia accumulation of pus follows, leading to the formation of a pyosalpinx. The placental site is, however, the important position from which a rapid spread of the poison takes place. The results produced through the spread of infection by the blood-vessels and lymphatics have already been mentioned but it is necessary to indicate what is meant by the term metritis dissecans. In this condition the uterine wall becomes infiltrated with pus and actual abscess formation—a true uterine abscess—may develop.

Having outlined the pathological anatomy, we now turn to the all-important question of treatment. All are agreed that prophylactic treatment is of prime importance, for if thoroughly and conscientiously carried out, puerperal infection will become an extremely rare disease. A labour should be conducted with the same care as one of the capital operations in surgery and the more clearly this is understood and appreciated by medical men and nurses the less will be heard about puerperal infection. It is difficult to make a naturally careless person, whether medical or lay, into a careful person, hence it is necessary to formulate rules for prophylactic treatment. 1. Careful antiseptic precautions before, during, and after labour. 2. Examine per vaginam as seldom as possible. Employ the abdominal method as an alternative. 3. Avoid prophylactic douches unless there be a gonorrhœal or septic discharge. 4. Repair all perineal lacerations after delivery. 5. Nurses should not be permitted to examine and all douches should be given under direct medical supervision.

The method of infection is, in the overwhelming number of cases, *contact infection*, and therefore anything which is brought in contact with the patient must be surgically clean. Many observers blame sewer gas as a cause of infection. I have never seen a case which I believed to be due to sewer gas and I have grave doubts if it ever causes puerperal infection. In arriving at a decision in this matter contact infection would have to be excluded. Concerning the necessity of restricting the number of vaginal examinations I fancy all are agreed, but it is of even greater importance to appreciate the necessity of surgical cleanliness before an examination is made. I am convinced that many men do not trouble to cleanse their hands properly before making an examination. The care of the hands should be an important duty in the life of every medical man. There is no excuse for a medical practitioner having dirty hands or nails, whatever class of practice he may possess. In the conduct of the third stage of labour it is imperative to refrain from contact with the genital tract except hæmorrhage or adherent placenta call for local manual treatment. The repair of perineal lacerations is an important aid in retarding the risks of infection and for this purpose silkworm gut[2] is the best suture material to employ. If the tear involve the rectum catgut should be used for the rectal sutures. With regard to the administration of douches some may say that a busy practitioner has not time to be able to exercise supervision. It is, however, better to avoid douching than to have a douche carelessly administered. Some years ago I suggested the employment of injections of serum as a prophylactic in cases where septic complications were likely to occur, in order to anticipate some of the dire results which may accrue. This special mode of employing serum will increase in usefulness when more trustworthy preparations are obtainable.

The curative treatment may be divided into (*a*) local treatment; and (*b*) general treatment.

Local treatment. 1. *Putrid endometritis.*—It is difficult to determine where a case of sapræmia ends and one of septicæmia begins, for the two processes may be combined. Hence it is a good rule in practice that when the temperature rises to 102° F. and is not due to other obvious causes sepsis should be suspected, the interior of the uterus explored, and a careful bimanual examination made of the appendages and broad ligaments.

In treating cases of puerperal infection it is necessary to do the work thoroughly and for this reason the patient should have an anæsthetic. It is far better to clean out the interior of the uterus once thoroughly than to make several more or less ineffectual trials without an anæsthetic. A medical man can always obtain a colleague to give the anæsthetic, and this additional trouble is well repaid if it prevents a death during the puerperium, than which there is nothing more harmful to the practitioner's reputation Having anæsthetised the patient and placed her in the lithotomy position you should systematically cleanse the genital tract from the vulva to the fundus of the uterus The external genitals should be washed with soap and water (preferably ether soap) and after removal of the soap swabbed with pledgets of wool, soaked in 1 in 2000 corrosive sublimate lotion The vulvar hairs should be cut short and carefully cleansed, or if the patient is very dirty the vulva should be shaved If the perineal wound has suppurated all stitches should be removed at once in order to establish free drainage "Puerperal ulcers," wherever situated, should be touched with tincture of iodine or pure carbolic acid The vaginal canal should be swabbed out carefully with 1 in 2000 corrosive sublimate, and in doing this, as in all other manipulations adopted in the treatment of these cases, the utmost gentleness should be employed so as to avoid opening up fresh surfaces for infection Any attempt at "violent swabbing" should be unhesitatingly condemned

---

[1] Producing a kink in the uterine canal.

[2] Silkworm gut should be boiled for half an hour and then placed in a solution of 1 in 1000 corrosive sublimate. It can be carried in the obstetric bag, contained in a small stoppered bottle.

I have found the employment of rubber gloves to be of great service in the treatment of puerperal infection These gloves should be boiled in a clean pot for five minutes and are easily slipped on the hands after dipping into a solution of lysol The rubber gloves protect your own hands, protect your patient and protect your other patients from being infected Whereas it is universally recognised that hand sterilisation is probably impossible, rubber gloves can be rendered sterile, and as there is little risk of puncture they are specially suitable for puerperal cases Their cost is small—2*s* 6*d* —and I would recommend every practitioner to buy two or three pairs At the same time it is essential to cleanse the hands as carefully as if gloves were not to be worn I do not put on the gloves until I have cleansed the external genitals The posterior vaginal wall is retracted by means of a metal speculum All the instruments employed should be made of metal throughout They should be boiled for half an hour, then placed in a solution of 1 in 40 carbolic lotion ready for use The cervix is now seized with a vulsellum but the uterus should not be pulled downwards to any great extent If the cervix is not sufficiently dilated one or two metal dilators should be passed in order to facilitate the introduction of the finger

In palpating the interior of the uterus it is an advantage to use the middle finger and at the same time with the external hand to push the fundus of the uterus slightly backwards Aided by the straightening of the uterine canal thus produced and the increased length of the middle finger a more thorough exploration of the cavity can be obtained With the finger in utero you determine if there be anything in the cavity, and here let me say that if there be some retained product in utero and you remove it the patient will probably get well The bad cases are those where nothing is found in the cavity of the uterus In the vast majority of cases the finger is quite able to remove any retained products and no instrument is required After this digital exploration the uterine cavity should be swabbed out with pledgets of wool or small squares of gauze[3] These should be prepared ready in a bowl of 1 in 4000 corrosive sublimate They are partially wrung dry and then wound round a pair of long uterine forceps and used gently to swab the interior of the uterine cavity The meshes in the gauze are advantageous in removing smaller pieces of tissue These swabs are applied until the uterus is thoroughly cleansed and if carefully done this is most effectual This method, which I have employed for several years, obviates the necessity of using an intra uterine douche and is, I believe, more effectual There is the further advantage that the only instrument required is a pair of long forceps I do not advise packing the interior of the uterus with gauze, although if carefully done there is no serious objection to its use The gauze should be removed in 48 hours If an intra uterine douche be employed the same precautions as to gentleness and thoroughness are required The solution should be weak and used in large quantity—four or five pints of a 1 per cent lysol solution or a 50 per cent solution of alcohol Boiled water or normal salt solution (a teaspoonful of common salt to the pint of water) is convenient to use, but unless it has been possible to carry out all the manipulations with great care and cleanliness it is better to employ the former solutions I have said nothing about the use of the curette in the treatment of these cases The finger can easily remove what should come away, whilst the curette only opens up fresh channels of infection Moreover the uterine wall is so soft that it is necessary to be very careful lest considerable damage should be done If curetting be attempted a blunt instrument should be used with great gentleness

Whatever method of intra uterine treatment be adopted it is well to give the patient vaginal douches twice daily of 1 in 4000 corrosive sublimate which wash away any discharge accumulating in the vaginal canal The administration of ergot is helpful in promoting uterine involution As has been said, the majority of cases of putrid endometritis if intelligently treated get well It is otherwise with the second group of cases—viz , those of septic or streptococcal endometritis

2 *Septic endometritis* —The local treatment of these cases is carried out on the principles already detailed in the treatment of putrid endometritis Here, however, the curette should certainly not be used, as the micro organisms have already penetrated deeply into the uterine muscle and are beyond the reach of intra uterine treatment On examining the interior of the uterus it will probably be found to be quite smooth and it is these cases which are the most dangerous Careful swabbing of the interior of the uterus should be employed, as has already been described, and for these cases also it is to be preferred to douching Intra uterine douching[4] is, however, largely practised and some authorities claim to have had good results from constant irrigation with very weak solution—e g , 2 per cent boric acid Whichever method be employed it is better to be done once thoroughly than to make repeated ineffectual attempts Indeed, there is a distinct danger in subjecting these patients to too much local treatment, for where there is a general infection other means must be employed to combat the microbic invasion Intra uterine treatment is further contra indicated where septic phlebitis or parametritis exists

It must be clearly understood that there are considerable shock and constitutional disturbance associated with intrauterine treatment in puerperal infection The temperature usually rises and even a rigor may occur, although there may be ultimately a fall in the temperature For this reason it is important that the patient should not be too frequently examined as so often happens in bad cases The anxious friends are probably desirous of obtaining another opinion if the patient is not rapidly improving and probably the interior of the uterus is again explored I am convinced that many patients would do well if they were really left alone, as rest is one of the best of all therapeutic agents If there be a widespread infection local intra uterine treatment will not avail and if the uterus has been once explored and proved to contain nothing no further intra uterine manipulation should be attempted

General treatment Serum —It must be admitted that up to the present time the results obtained from the employment of serum have been disappointing Moreover, in the majority of published cases other methods of treatment had been emplo [illegible] ult to determine the partic [illegible] treatment Recently more [illegible] and by cultures made from the lochial discharge it is possible to determine the variety of micro organisms present This is a most important step and although a trustworthy serum has not yet been produced no doubt further experiments will succeed in obtaining a trustworthy polyvalent serum The serum may, as already suggested be employed as a prophylactic where septic complications are likely to occur—e g , serious obstetrical operations In other cases it is necessary to begin this treatment early in the disease giving 20 cubic centimetres two or three times in the 24 hours if needful Professor Bumm[5] of Berlin has recently published in the *Munchener Medicinische Wochenschrift* for 1904 No. 25, the results of treatment with Aronsohn's serum, which appear to be more encouraging, but still in the very severe cases no serum as yet manufactured seems to be efficient *It is*, however, to be hoped that an efficient serum may yet be put upon the market

In the treatment of puerperal infection it is necessary to maintain the patient's strength by the frequent administration of a fluid, easily digested diet and, above all, by the free administration of alcohol in large doses which are well borne in this disease. Tepid sponging with vinegar and water is comforting to the patient and tends to reduce the temperature. Immersing the patient in a cold bath for ten minutes, which is cooled gradually three degrees lower, followed by the employment of a cold douche, may be tried in desperate cases. Poultices applied to the hypogastrium are beneficial in peritonitic cases and for the same purpose ice-bags may be used. The subcutaneous injection of normal saline solution is a valuable remedy, assisting in the elimination of toxic material.

---

[3] French obstetricians employ an instrument like a bottle brush made of strong quills called an "écouvillon"

[4] 50 per cent. alcohol, 1 per cent carbolic solution, 1 per cent. lysol

[5] He finds the serum acts best in severe streptococcal endometritis, phlegmasia alba dolens, and pure septicæmia, without localisation

Drugs.—Quinine is still a drug upon which reliance may be placed in the treatment of puerperal infection but I do not recommend you to give it in very large doses, for I have found that smaller doses are quite as efficacious. Sulphate of quinine given in doses of from three to six grains every three or four hours, combined with carbonate of ammonia in an effervescent mixture, is a good prescription. To this may be added tincture of digitalis, tincture of nux vomica, or liquor strychninæ hydrochloratis, according to the condition of the pulse. This effervescent mixture can be taken even in the presence of the nausea and loathing of food which are so common in this disease. Another drug which is very valuable in puerperal infection is calomel which should be given in frequently repeated small doses in order to maintain a slight amount of diarrhœa.

In two severe cases which I recently saw in consultation the administration of calomel had more effect in reducing temperature than large doses of quinine. When quinine and calomel were given together the temperature fell and the patient appeared to be better, but when quinine was given alone no lowering effect on the temperature was noted; indeed, it became slightly elevated. Calomel was given alone and a marked improvement resulted. In one of these cases the temperature rose to 107° F., but under this treatment both patients completely recovered. During the administration of calomel you should watch for signs of mercurialism. This does not happen so frequently if diarrhœa is produced by the medicine. In one patient who exhibited marked tenderness of the gums the calomel did not produce diarrhœa. When signs of mercurialism exist the drug should be discontinued and sulphate of magnesia should be given. As the condition of the patient improves on the quinine and calomel treatment a change may be made and large doses of perchloride of iron may be substituted, together with sulphate of magnesia to keep the bowels acting regularly. If you give the perchloride of iron when there are nausea and slight vomiting it is not well borne by the stomach, whereas the effervescent quinine mixture rarely disagrees. I advise you, then, to begin with quinine and calomel and in the later stages to administer perchloride of iron and sulphate of magnesia. For the relief of pain, if severe, some preparation of opium may be required. You may inject morphine subcutaneously or give it in a suppository; but I believe it is better to be avoided. It is not wise to attempt to control the diarrhœa unless it is excessive and then the administration of Dover's powder will be found useful, given in doses of from ten to 30 grains.

Surgical treatment.—The presence of a purulent collection in the pelvis calls for prompt surgical treatment. Parametric abscesses must be opened and drained. Where the pus is situated in the lumen of the Fallopian tubes (pyosalpinx) or in the substance of the ovary (ovarian abscess) immediate operation is required. If the swellings are adherent and accessible from below the pus should be evacuated by vaginal section; in other cases the abdominal route is indicated. Hysterectomy has been advocated and adopted in the treatment of puerperal infection but it has only a limited application. Where a general infection is present the removal of the uterus is not only attended by very grave risk but could not be expected to benefit the patient. If, however, there is localised infection confined to the uterine walls hysterectomy is indicated and the results obtained are good. Abscess formation in the uterine walls and infected myomata are the conditions which usually call for this operation. In those distressing cases of criminal abortion where the uterine wall has been perforated hysterectomy might be tried if the general condition of the patient were favourable. As an adjunct to other methods of intra-uterine treatment, especially where peritonitis exists, an opening may be made into Douglas's pouch by incising the posterior vaginal wall. This method was strongly advocated by the late Dr. Pryor of New York, who also recommended packing the pelvis with gauze. It is better, however, to drain the pelvis with one strip of gauze which should be removed in 48 hours. A gauze drain acts well if the peritoneal effusion is serous. If it is purulent a tube is to be preferred.

A REPORT ON 100 CONSECUTIVE ABDOMINAL HYSTERECTOMIES (ATTENDED WITH RECOVERY), PERFORMED AT THE MIDDLESEX HOSPITAL AND THE CHELSEA HOSPITAL FOR WOMEN.

By J. BLAND-SUTTON, F.R.C.S. Eng.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; AND SURGEON TO OUT-PATIENTS, MIDDLESEX HOSPITAL.

SOME cynics among surgeons regard statistics as "lies in figures" calculated to impose upon the credulous. It is somewhat interesting in this connexion to mention that a statistician of some note who flourished in 1660, Herman Conring, was a professor of medicine and politics. It is quite certain that in medicine, using the term in its broadest sense, statistics or the "employment of figures" is an important means of investigation. Indeed, whatever view cynical writers take in regard to the use of statistics "it is impossible to get over the fact that in meteorology, medicine, and other physical sciences statistical inquiries are plainly and obviously examples of the employment of a method, like microscopy, spectrum analysis, or the use of the telescope" (Hooper). It is worth recalling that one of the earliest examples of statistical writing, from the medical point of view, in this country dealt with *Bills of Mortality* relating to London, 1666. In considering a statistical statement of any kind the first thing is to understand the point or points requiring elucidation and the source of the facts. The object of the present communication is to demonstrate that with the strict application of Listerian principles in the form known as aseptic surgery it is possible for a surgeon to perform abdominal hysterectomy successfully in a well-found hospital 100 times consecutively for a variety of uterine diseases. The abstracts of cases supporting this statement have been compared with the hospital books by the officials in charge of them at the time the operations were performed. Mr. F. Lionel Provis and Mr. J. Howell Evans allow me to state that they verified the references for the Chelsea Hospital for Women; whilst Dr. W. F. Victor Bonney and Mr. Aslett Baldwin sanction the statement that they have verified the references to the patients treated at the Middlesex Hospital. An account of the first 58 cases in the list appeared in the *Clinical Journal* of April 20th, 1904, p. 1, but in the present communication an additional (or supplemental) account is given of the patients' condition. For these subsequent notes I alone am responsible and the source of the information is given in all cases where the request met with success. Great care and pains have been taken to secure these reports in order to show that in the majority of instances the patients derived benefit from the operation, for it is necessary to remember that *recovery* from an operation is not always equivalent to *success* from an operation. A careful study of these supplemental reports is very instructive and shows that in the majority of cases the patients require six months or even a year to obtain the full benefit of the operation, especially those who were profoundly anæmic from profuse menorrhagia.

It is important to point out that these operations were not only performed in a public institution but were carried out in the hospital theatre accessible to qualified medical men and women; every operation in the list was witnessed by members of the profession other than those of the official staff of the hospital. In no case was an exploratory operation performed or any case abandoned as too difficult. Operative treatment was not refused to any patient save those with very extensive cancer and, except in this dreadful disease, there was no picking and choosing. Throughout this communication the term "sub-total hysterectomy" will replace the cumbersome expression "supravaginal hysterectomy" as signifying the removal of the body of the uterus with a

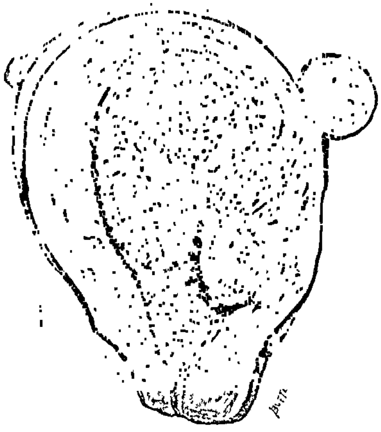
variable portion of its neck. This change of terms is desirable, for the operation which has given me the best results is not quite what would be called a "panhysterectomy" [illegible]
covered [illegible]
careful [illegible]
vaginal hysterectomy led observant operators to notice that those cases did best in whom the supravaginal cervix had been most freely removed; as a matter of fact, in the majority of my operations classed as supravaginal hysterectomy the only part of the uterus left is the vaginal portion of the cervix and after the operation is completed the united surfaces of the peritoneum merely appear as a slightly raised ridge across the pelvic floor, so that a surgeon inspecting the operation area from above would imagine that a total hysterectomy had been performed. On the other hand, if the cervix be examined from the vagina six months after the operation it will appear natural to the eye and touch. This is a matter of importance, as the operation in no way impairs the pelvic floor or hinders the function of the vagina. For this method the term in familar use among Parisian surgeons, "sub-total hysterectomy," is peculiarly suitable. The morbid conditions of the uterus which rendered radical operation necessary in these patients fall into five groups: fibroids and adenomyoma, 81; cancer, four; sarcoma, one; chronic inflammatory disease of the uterus, four; and fibrosis, ten cases; these causes indicate the widening scope of hysterectomy.

Fibroids.—In 81 patients hysterectomy was performed for these tumours, including two cases of the remarkable disease known as diffuse adenomyoma of the uterus. The commonest condition which induced these patients to submit to operation was profuse and long-continued bleeding from the uterus. The ages of the patients varied from 27 to 69 years. It is necessary to draw attention to the fact that out of a total of 81 hysterectomies for fibroids 13 of the patients had reached the age of 50 years and upwards and in each of them it was necessary to perform a serious operation for a disease which is generally believed to become harmless about the forty-eighth year of a woman's life. Two of these are worth some special remarks. Case 72 had been known to have a uterine fibroid many years and she ceased to menstruate in her fiftieth year. In consequence the tumour diminished very materially. When she attained her sixtieth year the fibroid began to cause so much trouble with the bowel and bladder that she had to seek relief. A large tumour blocked up the inlet of the pelvis and pushed the cervix low into the vagina. At the operation I found a large conical fibroid firmly fixed in the pelvis like a cork; it required a fair effort to extract it and, as in all those exceptional cases which require surgical interference after the menopause, the operation was singularly easy and almost bloodless. The tumour had a transverse diameter of 4½ inches, a vertical diameter of 5½ inches, and in horizontal circ[illegible]
was a spinster [illegible]
ments will affo[illegible]
this fibroid blocked the pelvis.

The oldest case in this series is in some respects the most interesting. The patient (No. 91 in the list) had attained her sixty-ninth year and she knew for a quarter of a century that her abdomen contained a tumour which by its size and weight had been a source of great inconvenience and often actual distress. This woman when placed under my care had been suffering from profuse uterine hæmorrhage and it was on this account that she deliberately sought the aid of surgery. The tumour equalled in size and hardness the head of a man. She was very fat, had an umbilical hernia, and unfortunately her urine contained sugar to the extent of 12 grains to the ounce. By rest and diet the amount of sugar diminished and I performed hysterectomy. The uterus contained a fibroid with an average diameter of 12 inches (30 centimetres) which yielded the odour of stale fish and the uterine cavity contained a degenerating tumour with the microscopic characters of cancer. On account of the glycosuria the operation was quickly completed, occupying from the time the anæsthesia was begun to the application of the dressing 22 minutes. The patient recovered easily and quickly. She left the hospital on the eighteenth day for her home. In a letter reporting her subsequent condition Mr. J. C. R. Braine-Hartnell, in expressing his satisfaction that the operation had been undertaken, states that the previous 20 years of her life had been "20 years of misery." Such a case tells its own tale.

If I had been bent on selecting cases for the purpose o making good statistics it would have been easy in regard t this old lady to urge the presence of sugar in the urine a a bar to operation, and doubtless some practitioners woul have deemed it a manifestation of surgical prudence. It is however, useful to remember that operating on bad cases i very apt to ruin statistics but it frequently saves lives, an this is the main consideration.

Diffuse adenomyoma.—Among the fibroids there were tw examples of this condition; they are included with them because, in these two cases, the uterus also containe typical fibroids, and the clinical signs of the disease ar indistinguishable from those which indicate the existence o submucous fibroids and the treatment eventually required i the same—namely, hysterectomy—on account of the long continuing exhausting menorrhagia, which rest, drugs, an repeated curetting fail to cure.



A uterus in sagittal section showing diffuse adenomyoma, from a spinster 32 years of age. The gland spaces were cystic and filled with gelatinous material.

Fibrosis of the uterus.—The prominent symptom which renders hysterectomy necessary in this disease may be described as rebellious menorrhagia, for it defies rest, drugs, and repeated curettings. Dr. A. H. Freeland Barbour recently brought a case of this disease before the Obstetrical Society of Edinburgh[1] and the communication clearly shows that he appreciates the leading features of the morbid anatomy of this affection, which, as he states, is essentially one affecting the arteries of the endometrium before the menopause. Dr. Barbour also recognises the most important clinical aspect of the condition—namely, the manner in which the bleeding and the enlargement of the uterus simulate cancer of the corporeal endometrium and that in the way of treatment hysterectomy alone gives good results.

In the cases in the following list the operation performed was sub-total hysterectomy unless otherwise specified.

CASE 1.—A single woman, aged 49 years; fibroid; profound anæmia; Jan. 19th, 1903. This patient had been an invalid for several years. She writes, Jan 10th, 1905 "I have been earning my living as a governess housekeeper and never had one day in bed since the first month after the operation."

CASE 2.—A married woman, aged 33 years; fibroid, hæmorrhage and pain; Jan. 19th, 1903. *Bilateral oophorectomy had been performed five years previously for menorrhagia but without good consequences.* Reported in good health from Africa Jan. 25th, 1905. Letter from medical attendant.

CASE 3.—A single woman, aged 44 years; fibroid; hæmorrhage; Jan. 19th, 1903 "I am better now than I have been for the last ten years and people cannot understand how it is that I look so well after all the misery that I have been through before the operation." Patient's letter, Jan. 7th, 1905

CASE 4.—A married woman, aged 49 years; adenomyoma; Jan. 26th, 1903. "I saw the patient to-day; she expressed herself as feeling perfectly well; in fact, better than she had felt for years." Letter from medical attendant, Jan 5th, 1905.

CASE 5.—A married woman, aged 45 years; fibroid; hæmorrhage; Feb. 2nd, 1903. "I consider that I am very fortunate to be so well as I am as I have had no pain in my stomach since the operation, the only thing I perspire very much and flushing, but that is nothing to the pain I was in before the operation." Patient's letter, Jan. 11th, 1905.

---

[1] THE LANCET, Jan. 21st, 1905, p. 163.

Case 6.—A married woman, aged 35 years. A very large fibroid; March 2nd, 1903. Reported herself on her birthday, Jan. 9th, 1905. In excellent health.

Case 7.—A married woman, aged 35 years. Fibrosis; menorrhagia; March 2nd, 1903. In excellent health September, 1904, and placed her sister under my care for hysterectomy (see Case 82).

Case 8.—An unmarried woman, aged 48 years. Fibroids; hæmorrhage; March 9th, 1903. Re-entered the hospital for vesical calculus, July, 1904. Uterine stump quite free from the bladder.

Case 9.—An unmarried woman, aged 48 years. Fibroids; hæmorrhage; March 16th, 1903. Reported herself one month after operation with œdema of one leg.

Case 10.—A married woman, aged 52 years. Fibroids; hæmorrhage; April 6th, 1903. "I really enjoy life, which I never did before." Patient's letter, Jan. 25th, 1905.

Case 11.—A married woman, aged 35 years. Fibroids (? sarcoma), April 13th, 1903. In good health Jan. 10th, 1905. Letter from patient.

Case 12.—An unmarried woman, aged 45 years. Large and rapidly growing fibroid; April 13th, 1903. This patient has been under treatment at home for recrudescence of disease in her knee which afflicted her when she was a child. Letter from patient, January, 1905.

Case 13.—An unmarried woman, aged 35 years. Fibroids; hæmorrhage; April 20th, 1903. "My health is really good and strong, I am able to follow my work as a nurse (in a hospital for infectious diseases). Previous to operation my life was unbearable." Patient's letter, Jan. 16th, 1905.

Case 14.—A married woman, aged 38 years. Fibroids; profound anæmia; May 4th, 1903. "My health is very satisfactory." Letter from patient, Jan. 6th, 1905.

Case 15.—A married woman, aged 53 years. Fibroids; bilateral ovarian cysts; May 11th, 1903. "I have greatly improved." Patient's letter, Jan. 7th, 1905.

Case 16.—A married woman, aged 37 years. Fibroids; bilateral pyosalpinx; May 11th, 1903. "I am in good health except that I have at times sharp pain in the right side of the abdomen." Letter from patient, Jan. 6th, 1905.

Case 17.—A married woman, aged 43 years. Fibrosis; profuse menorrhagia; May 25th, 1903. "I am fairly well with the exception of frequent headaches and nerve troubles." Letter from patient, Jan. 15th. 1905.

Case 18.—An unmarried woman, aged 49 years. Fibroids; profuse menorrhagia; June 1st, 1903. "She is perfectly well." Letter from medical attendant, Jan 5th, 1905.

Case 19.—A married woman, aged 54 years. Fibrosis; menorrhagia; June 15th, 1903. Left for Ceylon some weeks later.

Case 20.—An unmarried woman, aged 45 years. Fibroids, very large; July 6th, 1903. "Feeling better than I have for years." Jan. 8th. 1905.

Case 21.—An unmarried woman, aged 47 years. Fibroids, very large, July 7th, 1903. In the October following (the operation) was able to commence work again. Patient's letter, Jan. 7th, 1905.

Case 22.—An unmarried woman, aged 52 years. Fibroids, very large; July 11th, 1903. "I am very well." Jan. 7th, 1905.

Case 23.—A married woman, aged 37 years. Fibroids; hæmorrhage; cyst of the right ovary; July 27th, 1903. (Middlesex Hospital.) "Enjoying the best of health." Patient's letter, Jan. 10th, 1905.

Case 24.—An unmarried woman, aged 46 years. Cancer of the body of the uterus; August 3rd, 1903. (Middlesex Hospital.) Letter returned, "Gone away," Jan. 10th, 1905.

Case 25.—An unmarried woman, aged 53 years. Fibroids and cancer of the body of the uterus; August 13th, 1903. (Middlesex Hospital.) This case was drained and she left hospital with a sinus. This closed some months later. She now complains of pain in the left side. Jan. 9th, 1905.

Case 26.—A married woman, aged 46 years. Fibroid and ovarian dermoid; August 17th, 1903. (Middlesex Hospital.) "She enjoys better health than she has done for years." Letter from medical attendant. Jan. 10th, 1905.

Case 27.—A married woman, aged 51 years. Fibroids; hæmorrhage; August 20th, 1903. (Middlesex Hospital.) "Is perfectly well as regards the operation for fibroids." Letter from medical attendant, Jan. 9th, 1905.

Case 28.—An unmarried woman, aged 47 years. Fibroid, degenerating; hæmorrhage; Sept. 7th, 1903. "I am beginning to feel much stronger." Letter, Jan. 16th, 1905. As a matter of fact, I can state that this patient is very well.

Case 29.—A married woman, aged 45 years. Fibroid, degenerating; hæmorrhage; Sept. 7th, 1903. "Her condition is much better than it has been for years." Letter from medical attendant, Jan. 6th, 1905.

Case 30.—An unmarried woman, aged 42 years. Fibroid; profound anæmia; Sept. 7th, 1903. In good health, September, 1904. Personal visit.

Case 31.—A married woman, aged 24 years. Septic endometritis; Sept. 7th, 1903. In good health when she left for Africa. Autumn, 1904.

Case 32.—A widow, aged 49 years. Fibroid; cancer of tube; Sept. 14th, 1903. Known to be in good health six months later and contemplating re-marriage.

Case 33.—A married woman, aged 32 years. Fibroid; hæmorrhage; Sept. 14th, 1903. "You will be pleased to hear that I was able to conduct and manage more business last summer than in any previous year." Jan. 7th, 1905.

Case 34.—A married woman, aged 31 years. Fibroid; hæmorrhage and degeneration; Sept. 21st, 1903. "For the relief of the operation I am most thankful. I hardly know myself, I feel so well." Patient's letter, Jan. 26th, 1905.

Case 35.—A married woman, aged 44 years. Fibrosis; hæmorrhage; Sept. 28th, 1903. Good report from medical attendant, Jan. 6th, 1905.

Case 36.—An unmarried woman, aged 40 years. Fibroid; profound anæmia; Oct. 19th, 1903. Had some trouble from a stitch but is now all right. Jan. 13th, 1905.

Case 37.—An unmarried woman, aged 23 years. Cancer of the cervix. Total hysterectomy, Nov. 2nd, 1903. Seen at frequent intervals since operation; in good health, October, 1904.

Case 38.—A married woman, aged 33 years. Fibrosis. Suspected to be cancer of the cervix; Nov. 9th, 1903. She is first-rate, is fat, and looks well. Letter from medical attendant, Jan. 10th, 1905.

Case 39.—A married woman, aged 38 years. Fibroid, very large. Dermoid; Nov. 16th. 1903. "I have now better health than I have ever had." Jan. 7th, 1905.

Case 40.—An unmarried woman, aged 44 years. Fibroid, large and growing; Nov. 23rd, 1903. "Fräulein —— is so well since her operation." Letter from her friend (Case 1), Jan. 10th, 1905.

Case 41.—An unmarried woman, aged 38 years. Fibroid: profound anæmia, Nov. 30th, 1903. "My condition is, on the whole, very satisfactory." Patient's letter, Jan. 11th, 1905.

Case 42.—An unmarried woman, aged 55 years. Fibroids; pain; Jan. 11th, 1904. Convalescence slow, and Jan. 5th, 1905, her medical attendant writes: "Is now able to take up her school duties so that when we bear in mind the wreck she was at the time of the operation I think it is remarkable."

Case 43.—An unmarried woman, aged 50 years. Cervix fibroid; retention of urine; Jan. 11th, 1904. "I still feel a weakness in the left side but beyond that I feel better and can walk better than I have done for some years." Letter from patient, Jan. 7th. 1905.

Case 44.—An unmarried woman, aged 59 years. Cancer of the body of the uterus; total hysterectomy; Jan. 18th, 1904. Suspicions of a recurrence, March 18th, 1905. Letter from medical attendant.

Case 45.—A married woman, aged 37 years. Fibroids, septic; Jan. 18th, 1904. In excellent health. Seen personally on Jan. 23rd, 1905.

Case 46.—An unmarried woman, aged 42 years. Cervix fibroid; Jan. 25th, 1904. "My health is now excellent." Letter, Jan. 7th, 1905.

Case 47.—A married woman, aged 52 years. Fibroids; hæmorrhage; Feb. 8th, 1904. Recovered slowly. "She looks the picture of health and feels quite well." Letter from medical attendant, April 2nd, 1905.

Case 48.—A married woman, aged 42 years. Fibrosis; profuse menorrhagia; Feb. 15th, 1904. Sent a post-card from the Matterhorn to show that she could climb a mountain in the summer, 1904.

Case 49.—An unmarried woman, aged 37 years. Subserous fibroid and diffuse adenomyoma; very profuse menorrhagia; March 7th, 1904. This patient, a surgical nurse, suffered from asthma and it was thought that if the metrorrhagia was stopped the severity of the asthmatic attacks might be lessened. This hope has not been realised, though the patient's general condition is greatly improved.

Case 50.—A married woman, aged 44 years. Fibroid; very large and painful; March 7th, 1904. This patient (a monthly nurse) writes, Jan. 16th, 1905: "I am pleased to say I am much better: the only thing I have to complain of, I have to hold my abdomen just by the navel when I cough or sneeze."

Case 51.—An unmarried woman, aged 43 years. Fibroid; profuse metrorrhagia; March 14th, 1904. This patient, a surgical nurse, writes Jan. 16th, 1905: "Quite well, having no pain or discomfort of any kind."

Case 52.—An unmarried woman, aged 42 years. Fibroid; excessive menstruation; anæmia; March 21st, 1904. "Patient never remembers feeling better." Letter from medical attendant Feb. 27th, 1905.

Case 53.—A married woman, aged 33 years. Fibroid; menorrhagia; March 21st, 1904. Total hysterectomy. Good report from the patient March 1st, 1905.

Case 54.—A married woman, aged 48 years. Fibroid; metrorrhagia; bilateral hydrosalpinx; March 21st, 1904. Patient is very well. Letter from medical attendant, Feb. 27th, 1905.

Case 55.—A married woman, aged 45 years. Cervix fibroid; menorrhagia; March 28th, 1904. Patient reports herself in good health. Letter, Feb. 28th, 1905.

Case 56.—A married woman, aged 43 years. Sarcomatous fibroid; intense pain; March 28th. 1904. Patient died in June, 1904. Dr. —— writes that she had much less pain after the operation.

Case 57.—An unmarried woman, aged 29 years. Fibroid; soft myxomatous; menorrhagia; profound (toxic) anæmia; March 29th, 1904. Patient keeping in good health. Letter, Feb. 28th, 1905.

Case 58.—An unmarried woman, aged 56 years. Fibroids; pain and dysuria; April 12th, 1904. Convalescence slow but satisfactory. Letter from patient, Feb. 27th, 1905.

Case 59.—An unmarried woman, aged 32 years. Fibroids; menorrhagia and pain; April 12th, 1904. In good health December, 1904. Personal visit.

Case 60.—A married woman, aged 52 years. Fibroids; excessive metrorrhagia; April 15th, 1904. Good report from the patient, Feb. 23rd, 1905.

Case 61.—An unmarried woman, aged 39 years. Fibroids; pain; April 15th, 1904. This patient had two large parovarian cysts removed on March 16th, 1903; the left ovary was not removed, nor were there any evidences of fibroids. Soon after this operation she began to suffer from profuse menstruation and pain and the former became so profuse as to interfere with active life. She writes, Feb. 28th, 1905: "I am much better since my last operation."

Case 62.—A married woman, aged 42 years. Fibroids; cystic ovaries and distended Fallopian tubes; April 16th, 1904. (Unable to trace this patient; she was in good condition when she left the hospital.)

Case 63.—An unmarried woman, aged 41 years. Cervix fibroid; menorrhagia; cancer of the colon discovered in the course of the operation, April 18th, 1904. Resection of the sigmoid flexure for cancer in the Middlesex Hospital, September, 1904. The patient subsequently reported herself in good health.

Case 64.—A married woman, aged 33 years. Chronic inflammatory disease of the uterus, tube, and ovaries; total hysterectomy, April 25th, 1904. Good report from the patient, Feb. 28th, 1905.

Case 65.—A married woman, aged 31 years. Fibroids; red degeneration; pain and menorrhagia; May 2nd, 1904. April 2nd, 1905, the medical attendant writes: "She is now quite well, but a month or so after her return home she had an attack of hemiplegia which cleared up completely."

Case 66.—A married woman, aged 40 years. Fibroids; profuse menorrhagia; May 9th, 1904. "Health much improved since the operation." Letter from patient, March 16th, 1905.

CA [illegible] ears. Fibroids obstructing labo [illegible] May 9th, 1904. The patient was [illegible] ood health January, 1905.

Case 68.—A married woman, aged 37 years. Cervix-fibroid; retention of urine; total hysterectomy and both ovaries removed May 16th, 1904. The patient made a slow convalescence. April 2nd, 1905, the medical attendant writes: "Looks very well; she has flushings and the symptoms of the menopause."

Case 69.—An unmarried woman, aged 48 years. Fibroids; May 16th,

1904. In good health March 13th, 1905. Letter from medical attendant.

[illegible] much more [illegible] good. Letter, March, 3rd, 1905.

CASE 73.—A married woman, aged 48 years. Fibroids; profuse menorrhagia; July 4th, 1904. Reported herself at the hospital, Feb. 27th, 1905, in good health.

CASE 74.—A married woman, aged 48 years. Fibroids; menorrhagia; July 4th, 1904. The patient was reported well, Feb. 23th, 1905, by her medical attendant.

CASE 75.—A married woman, aged 38 years. Fibrosis; metrorrhagia; July 11th, 1904. "The patient is much better." Letter March 3rd, [illegible]

[illegible] d to be in good health two months [illegible] menorrhagia; [illegible] Convalescence [illegible]

CASE 83.—An [illegible] roids; metrorrhagia; Sept. 28th, [illegible] (Middlesex Hospital) [illegible] patient (a nurse in a county asylum) says she feels better than she has done for years. Letter, March 28th, 1905.

CASE 84.—A married woman, aged 40 years. Fibroids; metrorrhagia; total hysterectomy, Oct. 3rd, 1904. No report since leaving the hospital.

CASE 85.—A married woman, aged 48 years. Fibroids; septic; continuous metrorrhagia; total hysterectomy, Oct. 3rd, 1904 "Her health has improved wonderfully since the operation." The patient left for India in November. Letter from medical attendant March 3rd, [illegible]

[illegible] roids; Oct. 3rd, 1904. [illegible] 1905 [illegible] vix fibroid; tightly [illegible] ient had done extra- [illegible] from medical attendant, March 31st, 1905.

CASE 83.—A married woman, aged 46 years. Fibroids; three of very large size and one impacted in the pelvis; Nov. 14th, 1904. "My wife is better now than she has been for years." Letter, March 6th, 1905.

CASE 89.—A married woman, aged 33 years. Fibrosis; persistent *bleeding; Nov. 14th, 1904. Good report from the patient*, March 31st, 1905.

CASE 90.—A [illegible] rrhagia; marked anæm [illegible] I have ever had it." [illegible]

CASE 91.—A [illegible] ngerous bleeding; dial [illegible] he body of the uteru [illegible] writes, April 4th, 1905, [illegible]

CASE 92.—A *married woman, aged 30 years. Fibroids, profuse* menorrhagia; marked anæmia; Nov. 28th, 1904. The patient made an excellent convalescence.

[illegible] oids; pain and [illegible] her work as a [illegible] h 28th, 1905 [illegible] uterus, active [illegible] 4. No report [illegible] *broids, small but* [illegible] pian tubes; total [illegible] e extraordinarily [illegible] 1905. [illegible] ibroids, pain and [illegible] from the patient Feb. 15th, 1905.

CASE 97.—A married woman, aged 35 years. Fibroids; menorrhagia; profound anæmia; Dec. 19th, 1904. Good report from the patient, March 10th, 1905.

CASE 93.—A married woman, aged 41 years. Fibroids; menorrhagia, anæmia; Dec. 19th, 1904. Letter from patient, Feb. 3rd, 1905. "Getting quite strong again."

[illegible] patient Feb. 3rd, 1905, and March 20th, 1905.

In addition to the 81 patients from whom the uterus was removed for fibroids and diffuse adenomyoma there were eight women in whom myomectomy or enucleation was performed, and one woman, aged 28 years, from whom a large soft fibroid weighing 14 pounds was removed from the round ligament of the uterus. This tumour grew into the abdomen like a subserous stalked fibroid. Each of these patients made an uninterrupted recovery. Myomectomy and enucleation are justifiable procedures in women [illegible] in married women so anxious [illegible] willing to run serious risks on the [illegible] children. Experience, however, teaches this stern lesson: after the enucleation of a fibroid in the procreative period of life a woman is 20 times more likely to grow more fibroids in her womb than to conceive successfully.

Brook-street, W.

ON PNEUMOCOCCAL SORE-THROAT WITH NOTES OF A FATAL CASE.

BY W. PASTEUR, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO THE MIDDLESEX HOSPITAL; CONSULTING PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

AMONG the acute inflammations of the faucial region there is one, pneumococcal angina, which has not apparently as yet received in this country the attention it deserves. At a recent public examination not a single candidate even mentioned this condition in discussing the differential diagnosis of diphtheria. Pneumococcal inflammations of the fauces and larynx are, however, well worthy of attention on account of the close clinical resemblance they may present to other acute inflammations of those regions, especially diphtheria.

The occurrence of inflammatory lesions of various mucous membranes, with or without membranous exudation, in association with pneumonia and broncho-pneumonia has been recognised for many years. A very remarkable case of this kind is recorded by Cary and Lyon.[1] But examples of primary inflammation of the faucial region are much more uncommon. Jaccoud,[2] T. K. Monro,[3] and others have placed on record cases of membranous sore-throat of pneumococcal origin which clinically were very like diphtheria. The [illegible] I am about to relate differ widely [illegible] example of another variety of [illegible] the "angine érythémateuse [illegible] authors.

Referring to the probable frequency of acute membranous tonsillitis and pharyngitis of pneumococcal origin, Foulerton[4] remarks that "the exact bacteriological identification in these cases is rendered difficult by the fact that the organism is a frequent parasite of the healthy mouth. But the number of cases in which there are the formation of a false membrane and destruction of the superficial layer of the epithelial membrane associated with the presence of the coccus in predominant numbers and without any of the other bacteria —B. diphtheriæ, streptococcus pyogenes, *and* saccharomyces albicans—which are known to cause similar lesions, leaves little doubt as to the fairly frequent occurrence of an acute membranous pharyngitis due to this cause."

A healthy, well-nourished boy, aged three and a half years, was seized with sudden illness on Oct. 24th, 1903. The prominent symptoms were sore-throat with great pain on deglutition and high fever, which had persisted. There was no initial vomiting nor had there been any signs of laryngeal implication or of pulmonary trouble. He had only taken small quantities of milk with much difficulty. He was admitted to the Middlesex Hospital on the fourth day of illness in *the following condition.* The face was pale with a dusky malar flush. The respirations (40 per minute) were not laboured. The pulse *(120) was soft, full, and regular.* The glands at the angle of the jaw were moderately swollen on both sides and very tender. The skin was dry and hot (temperature, 103° F). There were no signs of desquamation and no puffiness. There was no discharge from the nose or ears. A careful examination of the heart and lungs revealed no abnormal signs. A specimen of urine passed soon after admission gave a positive result to Ehrlich's diazo reaction; it was free from albumin. The uvula, soft palate, and faucial pillars on both sides were slightly œdematous and intensely red and glazed. Both tonsils were somewhat swollen and intensely injected. There were no exudation of any kind and no plugging of the follicles of the tonsils. The posterior wall of the pharynx could not be seen. The tongue was rather thickly furred and the breath was very offensive.

[2] [illegible]

[4] Transactions [illegible] 293.

Progress of case.—8000 normal units of diphtheria antitoxin were injected on admission and a swab was taken from the throat for bacteriological examination. The temperature ranged high throughout the illness, exceeding 103° every day and only once falling as low as 101°. On Nov. 7th the appearance of the throat was much the same. There were no signs of exudation. The patient had great difficulty in swallowing and frequent regurgitation of fluid through the nose. The enlarged spleen could be felt below the ribs [illegible] The swab cultures yielded an abundant [illegible] but no bacilli were present. Widal's [illegible] a negative result. No signs of broncho-pneumonia [illegible] There were considerable enlargement [illegible] of the glands at the angles of the [illegible] to feed through a nasal tube [illegible] enemata of milk and beef tea had been [illegible] since the 8th. On the 11th there were signs of cerebral [illegible] The child was curled up to one side with the [illegible] and the knees bent up. He strongly resented all interference, cried out at sudden noises, and had definite photophobia. No paralytic symptoms were observed. During the last two days the fœtor of the breath had increased and become distinctly gangrenous. On the 9th the throat was still intensely red and glistening, but to-day (11th) the whole of the uvula and the adjacent portions of the soft palate were brown and sloughing. There were no signs of peeling and the urine remained free from albumin. The nutrient enemata were omitted on account of rectal intolerance. On the 14th the temperature had been more remittent since the 11th and the patient was growing rapidly weaker. The throat was sprayed frequently with chlorine water but without appreciable effect on the fœtor and unsuccessful attempts had been made to irrigate the naso-pharynx with antiseptics. There was now a grey gangrenous slough involving the uvula and the palatal arches. The respirations had risen from 30 to over 70 per minute and signs of broncho-pneumonia had made their appearance in the left lung, both in the upper and lower lobes. Death took place on Nov. 15th, the twenty-second day of illness. There was slight diarrhœa during the last three days. There was no nasal discharge at any time.

Necropsy.—A post-mortem examination was made 31 hours after death, the weather being cold. The body was emaciated and somewhat rachitic. No beading of ribs could be seen. There was some excoriation at the right angle of the mouth. The whole of the soft palate, both pillars of the fauces, and the tonsils formed a large greenish gangrenous mass. The glotto-epiglottic fold and pyriform sinuses were also discoloured and bathed by a thin greenish purulent discharge. The sloughing area reached as far forwards as the hard palate. The glands at the angle of the jaw and those of the posterior triangles were much enlarged. The right pleura contained two and a half ounces of thin reddish pus. On the posterior aspect of the left pleura, just on a level with the bifurcation of the trachea, was a circular patch of softening. The œsophageal, bronchial, and mediastinal glands were enlarged. The bronchi were congested and contained some thick purulent exudation. The upper lobe of the left lung was congested. There was one small gangrenous patch on the posterior aspect. The lower lobe was riddled with patches of broncho-pneumonia which were becoming gangrenous. The largest gangrenous cavity was of the size of a hazel nut. There were similar changes in the right lung. A gangrenous patch of the size of a walnut was in the upper lobe and there were areas of collapse in the lower lobe. The heart was natural. The stomach was contracted and healthy. The œsophagus was healthy. The kidneys were somewhat enlarged and cloudy. There were cloudy swelling and much post-mortem discolouration in the liver. The spleen was enlarged and congested. As regards the head, the scalp, calvaria, and sinuses were natural. There were slight congestion of the pia-arachnoid and some excess of cerebro-spinal fluid. No meningitis was present. The brain substance was natural.

Bacteriology.—Cultures obtained post mortem from the pharynx and lungs were examined by Mr. A. G. R. Foulerton, who informed me that the diplococcus pneumoniæ was present in predominating numbers, together with a bacillus (probably the result of post-mortem infection) in smaller quantity. The diplococcus was tested on a mouse and found to be of normal pathogenicity for that animal.

The difficulties surrounding the clinical diagnosis in this case were very great. The child was too young and too desperately ill to permit of any really satisfactory examination of the naso-pharynx being made. Diphtheria antitoxin was injected as a precautionary measure only, for the sudden onset, severe initial symptoms, and persistent high temperature did not lend support to this view of the case. The absence of all exudation on the tonsils and fauces and the total absence of any signs of desquamation excluded the diagnosis of scarlet fever. On the whole, the appearance of the fauces and soft palate on admission more nearly resembled erysipelas than anything else but the very moderate degree of œdema militated strongly against this view. The possibility of a pneumococcal inflammation of the pharynx was carefully considered but could hardly be maintained in the face of the negative result of the first bacteriological examination. I am satisfied that the pharynx was the site of primary infection. The lungs were repeatedly examined and no signs of broncho-pneumonia or other lesion detected until the later stages of the illness when gangrene of the palate was already well marked.

The occurrence of gangrene in pneumococcal inflammations of mucous membranes is well established. Munro's patient recovered with a perforation of the faucial pillars and I may fitly refer here to a remarkable case which came under my notice some time ago and was placed on record by Foulerton.[5] The patient, aged 26 years, had suffered from a "quinsy" a fortnight before admission to the Middlesex Hospital and had been ill ever since. He died from pyæmia three days after admission. The necropsy revealed an almost universal pneumococcic gastritis, with extensive necrosis of the glandular layer of the mucous membrane of the stomach. There was a deepish ragged ulcer in the right tonsil. It seems probable that in this case the primary lesion was a pneumococcic infection of the right tonsil, though this was not proved bacteriologically.

I am indebted to my colleague, Dr. J. Kingston Fowler, for permission to mention a case of membranous laryngitis arising in connexion with an acute pneumococcal inflammation of the lungs. The patient, a man, aged 38 years, was admitted in the fourth week of an acute illness with signs of consolidation in the left lung. He lived for 34 days after admission, during which period the greater part of both lungs became consolidated. The necropsy revealed a very extensive pneumonia of both lungs with a small smooth-walled gangrenous cavity at the posterior apex of the left lower lobe. There was a patch of toughish adherent membrane on one of the vocal cords from which Mr. Foulerton obtained a pure culture of diplococcus pneumoniæ. This organism was also present in preponderating numbers in the cultures obtained from scrapings of the lung tissue just outside the cavity in the left lung. The patient had not presented any laryngeal symptoms.

A striking example of pneumococcal laryngitis has been recorded by Seuvre.[6] The case is that of a boy, aged eight years, in whom symptoms of laryngeal obstruction supervened in the course of an attack of "grippe." Tracheotomy had to be performed and pneumococcus in pure culture was obtained from pieces of membrane coughed up through the tracheotomy tube. It is clear from a consideration of recorded cases that pneumococcal pharyngitis may present different clinical forms. French observers who have paid some attention to the subject describe the following varieties:[7] (1) the suppurative; (2) the pseudo-membranous; (3) the follicular; (4) the inflammatory or erythematous; and (5) the herpetic.

The erythematous form was first described by Rendu and Boulloche.[8] The appearance of the fauces described by these observers agrees very closely indeed with that presented by my patient in the earlier stages of his illness. The etiology of their case was interesting. The patient, a nurse in a children's hospital, slept in a dormitory from which during the week preceding her illness three other nurses had been warded with acute pneumonia. Her illness developed very acutely with chills, intense headache, and high fever and subsided by crisis with profuse sweating and diuresis after a duration of only 36 hours. There were no pulmonary symptoms.

An altogether similar case is recorded by Gaultier[9] in a young man. Crisis occurred on the fourth day after an acute onset with rigor. There was a short relapse with recurrence of pharyngeal inflammation after an afebrile interval of six days. A fatal termination in pneumococcal pharyngitis is quite exceptional if one may judge by the recorded cases, and the occurrence of gangrene, which determined the bronchopneumonia in my patient, is also rare. Monro's patient furnishes the only other instance of this that I have come across.

[9] Loc. cit.

The local signs of pneumococcal pharyngitis are in no sense distinctive. The membranous form may closely simulate diphtheria and a bacteriological examination alone reveal the true nature of the case. Somewhat similar appearances are also met with in some cases of streptococcal inflammation of the throat[10] but here the exudate is usually thinner and looser in texture and less adherent than in pneumococcal or diphtheritic inflammations. More reliance may be placed, in my opinion, on the early symptoms and mode of onset. In pneumococcal sore-throat the onset is usually quite sudden, often with rigor or chills, the initial symptoms are severe, and the temperature rises rapidly to 103° or higher—a grouping of symptoms strikingly like those of pneumonia and very rarely met with in anything like the same degree in diphtheria or even in streptococcal pharyngitis. The disease tends to run a short course—from two to five days—but to this there are exceptions. The erythematous form of the affection is most likely to be mistaken for scarlatinal angina and here the diagnosis—apart from bacteriological findings—must rest mainly on the absence of other signs of scarlet fever. It is worthy of note that a considerable number of the recorded cases of pneumococcal sore-throat have been in adults.

Chandos-street, W.

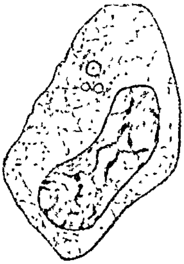
ON THE

RESEMBLANCES EXISTING BETWEEN THE "PLIMMER'S BODIES" OF MALIGNANT GROWTHS AND CERTAIN NORMAL CONSTITUENTS OF REPRODUCTIVE CELLS OF ANIMALS.[1]

BY J. BRETLAND FARMER, F.R.S.;
J. E. S. MOORE;
AND
C. E. WALKER.

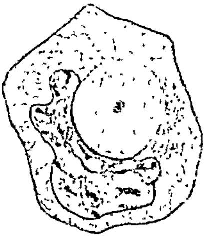
IT is proposed in the present communication to present the results of investigations bearing on the nature of those remarkable structures known as "Plimmer's bodies."[2] As is well known, these are found in many cancerous growths and are most commonly encountered in the younger or growing regions of the tumour. They appear in the form of vesicles and they consist essentially of a fairly well-defined wall containing a clear space in which is suspended a small darkly staining granule (Figs. 1 and 2). They are most commonly to be met with in tumours of a glandular or glandular-epithelial origin.[3] They lie in the cytoplasm of the cancer cell and usually in close proximity to the nucleus. In size they vary from excessive minuteness to that of the nucleus itself.

FIG. 1.



Example of "Plimmer's bodies" from scirrhus of the breast: three small "bodies" in an an archoplasm.

FIG. 2.



Later stage in the development of the "bodies."

The special interest attaching to them depends on the fact that they have commonly been regarded as peculiar to cancerous cells, although Honda[4] believes that he has occasionally also encountered them in inflammatory tissues. They have been variously interpreted. Some investigators have regarded them as parasitic organisms, more or less intimately connected with the etiology of the disease, whilst others have seen in them a differentiation of the cytoplasm of the cancerous cell itself. It has been suggested also that they might be derived from the centrosomes within the archoplasm,[5] but the observations of Benda[6] that centrosomes coexisted independently of them in the cell has rightly been held to disprove this hypothesis.

Our own investigations indicate, however, that there are good grounds for reconsidering the whole position and a comparison of the processes that normally obtain during the final stages of development of the reproductive elements in man and the other mammalia appears to us strongly to suggest that a parallel between the Plimmer bodies of cancer and certain vesicular structures occurring regularly in the gametogenic, but not in the ordinary somatic, cells may be found to hold good.

It was shown by one of us[7] in 1895 that during the prophase of the heterotype (first maiotic) mitosis of the spermatogenetic cells the archoplasm undergoes a highly characteristic and peculiar metamorphosis. In normal somatic, or premaiotic, cells the archoplasm is seen to lie beside the nucleus as a dusky mass of protoplasm in which are contained the centrosomes. That is, the attraction sphere consists of the archoplasm *plus* the centrosomes. But during the prophase of the heterotype mitosis these constituents become separated. The centrosomes are found to lie *outside of*, and detached from, the archoplasm. At the same time the archoplasm itself undergoes a change. It becomes vesiculated and finally, at the close of this cell generation, it is lost in the general cytoplasm of the daughter cells.

In the prophase of the second maiotic division (homotype) the same phenomena recur. When the homotype mitosis is over the constituents of the sphere, or at least some of them, enter into direct relation with parts of the spermatozoon which arises by further differentiation of the cell. As regards the archoplasm, with which we are more directly concerned, it is again seen to contain a number of minute vesicles which continue as before to grow in size, whilst each contains a single refractive and stainable granule (Fig. 3). Subsequently several of these vesicles fuse together so that at a later stage in the metamorphosis of the cell into a spermatozoon there only remains a single large clear body, bounded by a distinct membrane, containing in the centre one or more darkly staining granules (Fig. 4).

[7] Moore: Internationale Monatschrift fur Anatomie und Physiologie, vol. xi.

This body, originally described by one of us in 1895 as the archoplasmic vesicle, is a very conspicuous and apparently constant feature peculiar to the spermatogenetic cells of, at any rate, the vertebrata and it has since been encountered beyond that group by other observers. When fully developed it often assumes a size approximating to that of the nucleus. Indeed, the latter is often deformed and made to assume a crescentic or cuplike shape owing to the enlargement of the adjacent archoplasmic vesicle. The vesicle and its contents ultimately form the so-called "cephalic cap" of the spermatozoon.

The remarkable similarity between the structure just described and those known as Plimmer's bodies will have become obvious. It is not, perhaps, accidental that just as in the case of nuclear divisions, so also in the cellular inclusions, a parallelism between the cells of reproductive tissues and of cancer cells should be found to exist. But we do not on this account regard the cells of cancer as *identical* with those of the sexual cells, as we were careful to point out in our first communication in 1903. But the resemblances between what we have termed gametoid and the true gametogenic cells now seem to be even more significant than they appeared to be at that time. Both classes of cells are autonomous to a very high degree and both possess the faculty of continuous or intermittent multiplication independently of the tissue requirements of the organism. And finally both exhibit cellular and nuclear metamorphoses which not only, *mutatis mutandis*, resemble one another, but differ materially from those pertaining to the normal somatic cells.

It is possible that the malignant elements are the outcome of a phylogenetic reversion, as was suggested by Sir William Collins, but the matter is obscured by the disturbing influences that have been operative during the actual ontogeny of the cells and tissues from which these elements have sprung. If this be so the connexion apparent between gametoid and the true reproductive cells will acquire a still deeper significance. But we propose to reserve the discussion of this question for another occasion.

In thanking those who have helped us with material we would mention especially Mr. Plimmer himself who has most kindly placed preparations at our disposal. We would further record our indebtedness to the Imperial Cancer Research Fund for a grant in aid of our investigation.

ACUTE AORTITIS.

By WALTER BROADBENT, M.A., M.D. Cantab., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.

Acute aortitis is so rarely seen that the following case seems worthy of record.

A man, aged 45 years, came to my out-patient department at the Sussex County Hospital on March 1st complaining of pain across the left chest after partaking of food. He said that for three months he had had some discomfort in the upper abdomen an hour or more after meals and for about ten days there had been definite pain in the lower part of the left chest, mainly late in the afternoon, which he attributed to indigestion. He did not look ill. His tongue was slightly furred and his bowels were regular. His pulse was 80, the artery was a little above the normal size, the walls were not much thickened, and the wave was very easily compressible, not collapsing. The apex beat was in the vertical nipple line two inches below the nipple; the impulse was poor. On auscultation a moderate first sound, a second sound, and a short diastolic murmur were heard. At the pulmonic and aortic cartilages there were soft second sounds and a short diastolic murmur. In the neck the second sound was distinct. There had been no rheumatic fever. No history of syphilis was obtained. There was no tenderness in the epigastrium and the stomach was not dilated at all. The pain never spread to the arm and the man thought that food had more to do with it than exertion, but as the physical condition of the stomach seemed good and that of the heart doubtful a mixture containing spirit of nitrous ether and strychnine was ordered.

A week later the patient came again saying that the pain had become steadily worse and for four days it had been shooting all over his chest and down his left arm. It was now exceedingly severe and the attacks were almost continuous. He looked pale, anxious, and worn, though a week before his appearance had been healthy. His pulse was 96 and was very easily compressible. The apex beat was barely perceptible and the first sound was weaker than before. He was sent to the hospital for admission and an hour later, just after getting into bed, he died suddenly.

At the post-mortem examination the most striking feature was the bright red colour of the first three inches of the aorta inside and outside. The aortic valves were found to be practically competent by the water test. They were thickened and showed signs of atheroma. The mouths of the coronary arteries were almost completely occluded and only a bristle could be passed through either. A calcified plaque formed part of the obstruction to the right but the other was blocked by swollen intima. Areas of old atheroma were scattered on the aortic walls, and, in between, the intima was bright pink and swollen in patches, the appearance corresponding closely to the water-colour drawing in Sir William Broadbent's work on "Heart Disease" (third edition). Outside the adventitia was red and injected. This extended up to about the origin of the innominate artery. There was no spread of inflammation into the left ventricle. The heart muscle seemed firm.

Dr. F. G. Bushnell kindly cut sections of the aorta and heart muscle. In those of the aorta there was a perivascular infiltration with leucocytes round the vasa vasorum of the aortic wall, more marked in the outer coat. The sections of the heart muscle stained in Sudan III. and osmic showed a singular absence of change. The striation of the muscle and the nuclei appeared normal and no fatty or fibroid degeneration was found; all that could be seen was a slight pigmentary deposit near the nuclei. No bacteriological investigation was made.

As in previously recorded cases this was an acute inflammation attacking an aorta already damaged by atheroma. The primary cause of death in this case must have been the blocking of the orifices of the coronary arteries by the swelling of the intima, since one cannot imagine the heart continuing to beat for long when only a bristle could be inserted into either coronary artery, and the condition of the heart, free from fatty degeneration or fibrosis and with the muscle in apparently good condition, shows that the obstruction to the blood-supply was not of long duration. The clinical history of the case also bears this out, there being no true attack of angina pectoris until four days before death and then there was a rapid increase in the number of the attacks.

The duration of the disease from the first symptom which could be called cardiac pain was only 17 days, the usual length being from two to six months, but Dr. F. J. Poynton relates a case of sudden death[1] due to acute aortitis with no history of previous illness. He gives details of two cases but in neither was there any inflammatory obstruction of the coronary arteries; in one there was fatty and in the other fibroid degeneration of the heart wall, and in both he describes the nuclei of the muscle fibres as staining indistinctly and the striation as feeble, and he attributes the fatal termination to these changes. In the case described above there were none of these degenerations of the cardiac muscle.

Brighton.

Medical Golfers' Association *v.* Bar Golfing Society.—The annual match between teams representing the Medical Golfers' Association and the Bar Golfing Society took place at Woking on Saturday, May 20th. A year ago the match was played at Burnham Beeches and after an exciting finish the barristers gained a victory by one point. For Saturday's match strong teams were chosen and fair golf was witnessed, the Bar being easily victorious. The following took part in the match. Medical Golfers' Association: Dr. A. W. Daniel, Dr. W. J. Howarth, Mr. H. Dane, Dr. Percy Kidd, Dr. C. Webb, Dr. F. F. Caiger, Dr. H. P. Hawkins, and Dr. H. Low. Bar Golfing Society: Mr. H. W. Beveridge, Mr. J. Crabb Watt, Mr. L. Mossop, Mr. C. F. Parton, Mr. H. T. Wright, Mr. F. S. Jackson, Mr. R. H. Balloch, and Mr. M. Shearman, K.C. In the singles the Bar scored seven points to one scored by the Medical Profession, while in the foursomes the Bar won by three points.

A REGULATING CHLOROFORM INHALER.

BY A. G. LEVY, M.D. LOND.,
ANÆSTHETIST TO GUY'S HOSPITAL; ASSISTANT ANÆSTHETIST, NORTH-WEST LONDON HOSPITAL.
(From the Laboratory of Pathological Chemistry, University College, London.)

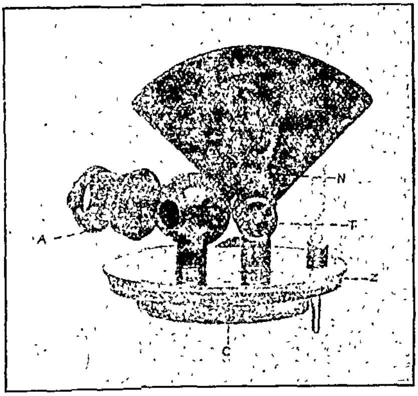
THIS apparatus is a simplified and improved form of that which I described recently to the Royal Medical and Chirurgical Society.[1] It is unnecessary to enter very fully here into the details of the methods employed and the principles involved in the construction and use of the appliance, as these matters were fully discussed in the paper referred to.

The complete apparatus is shown in Fig. 1, and in Fig. 2 some parts of it are seen from behind. In order to indicate more clearly its intimate construction I have provided a diagram (Fig. 3) of its main portion as if seen from above in a plane projection.

The apparatus may be described as consisting of a face-piece and a body which communicate through the medium of a length of wide-bore aluminium pressure tubing. This tubing is connected to the face-piece (F, Fig. 1) by a double junction in the form of two hollow metal globes, which rotate upon one another and upon the mount of the face-piece. Upon the summit of the one globe (that further from the face-piece) is fixed a light hinged aluminium valve, opening outwards and providing for the escape of the expired air. The double joint enables one to dispose the tubing conveniently.

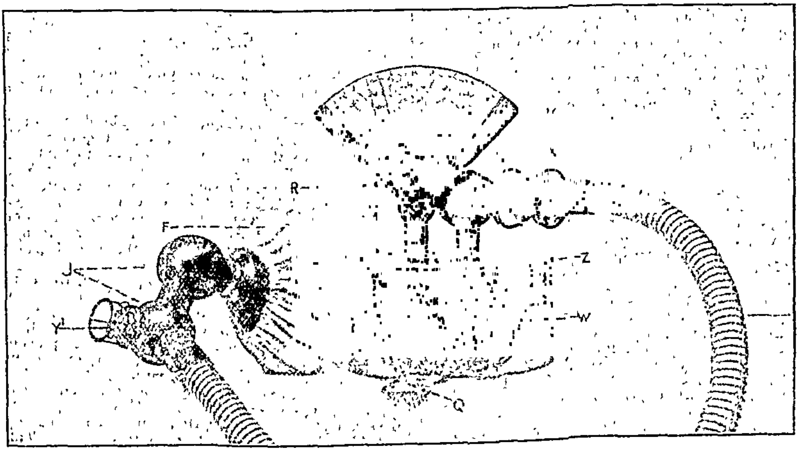
The body consists of the following parts. A shallow circular vessel, 11 centimetres in diameter and 2·7 centimetres in height, contains the chloroform (C, Figs. 2 and 3). This vessel forms part of the cover of a bigger vessel (W, Fig. 1) which is filled with hot water and constitutes a water bath, the thin copper bottom of the chloroform vessel alone separating the chloroform from the water. A spout (*s*, Fig. 3) is fixed in the cover and from it the chloroform chamber is filled through an opening in the bottom of the latter. Two ounces of chloroform are required to fill the chamber up to a level indicator (a small loop of wire) which is fixed in the spout. There are two tubular apertures (15 millimetres in diameter) in the roof of the chloroform chamber (*i* and *o*, Fig. 3) which provide for the ingress and egress of the air current, which is directed from one to the other in a circular direction around the chamber and over the surface of the chloroform by means of the vertical partition and circular walls, the position of which is indicated by the dotted lines (*p*, Fig. 3). The inlet (*i*) may be closed and opened by the tap (*t*), this being itself manipulated by the index lever (*h*), which travels over the scale plate (*y*). The outlet tube communicates directly with the metal globe (*g*), and through it with the aluminium tubing, an aluminium valve, inclosed in a glass observation chamber (X, Fig. 1), being interposed at the junction. The globe (*g*) has also a circular air inlet (A, Fig. 2) 18 millimetres in diameter, which is permanently open.

FIG. 2.



Back view.—The cover removed from the water bath, showing the exterior of the chloroform chamber (C), the aperture for the pure air (A), and the aperture (N) leading to the tap.

FIG. 1.



G, Globe in which air and chloroform currents mix. H, Index-hand. Q, Foot, which is clamped to the edge of a table. R, Thermometer. X, Glass valve chamber (containing inspiratory valve). Y, Scale

---

[1] Transactions of the Royal Medical and Chirurgical Society, 1904-05; THE LANCET, Nov. 26th, 1904, p. 1496.

When inspiration is performed through the face-piece air is drawn in from two sources—viz., pure air through the hole (*a*) and vapour-laden air through the circuitous route of the chloroform chamber *viâ* the tap, as shown by the dotted arrows in Fig. 3, and these two currents intermingle in the globe (*g*) and form a complete mixture in their course through the aluminium tubing. During expiration reflux is prevented by the inspiration valve (v^2) and the expired air escapes through the valve on the face-piece. The proportions and dispositions are such that when the tap is fully open between twice and three times as much pure air passes in through the hole (*a*) as passes in at the tap. The chloroform-laden current is thus diluted to between one-third and a quarter of its original strength and at any definite temperature of the water bath a mixture of definite percentage is drawn to the face-piece. By partially closing the tap less air passes over the chloroform and proportionately more through the aperture (*a*), so that a mixture of greater dilution is inspired. For each position of the tap handle a definite percentage dilution is marked upon the scale.

FIG. 3

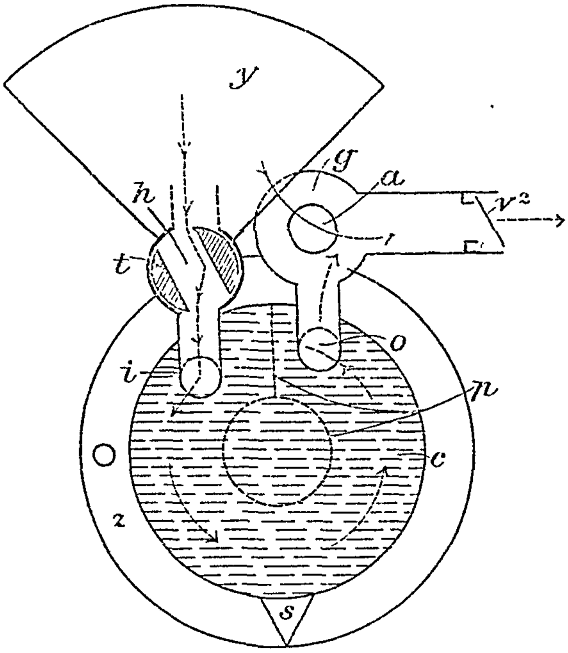


Diagram of the apparatus as if seen from above in plane projection. The air aperture (*a*) is shown as if in the front of the mixing globe (*g*). The horizontal shading represents the chloroform surface, as if seen through the cover. The dotted lines represent structures as if seen through transparent superstructures. The arrows indicate the course of the air currents. *i*, Inlet to chloroform chamber. *o*, Outlet from chloroform chamber. *p*, Partitions. *s*, Spout. v^2, Inspiration valve.

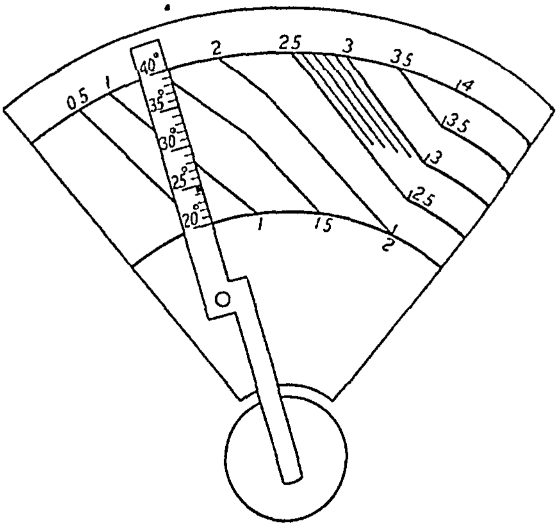
The water surrounding the chloroform has a higher specific heat than has the latter and it is thus able to maintain the temperature of the chloroform which would otherwise tend to fall to a low level during abstraction of heat in the course of its evaporation. The water bath is filled with hot water (at 40° C.) in order to increase the vapour-yielding capacity of the chloroform and this is necessary because a strong vapour current is required in view of the subsequent dilution which occurs. Whilst the temperature of the water, and hence also of the chloroform, remains constant (other physical conditions being the same) the percentage of vapour inhaled depends solely upon the position of the index hand, and the percentages at a temperature of 40° C. are marked off at 0·5 per cent. intervals along an arc at the top of the scale plate (see Fig. 4).

As the water gradually cools down to the temperature of the room provision is made for reading off percentages at lower temperatures. A thermometer (R, Fig. 1) is therefore provided to indicate the temperature of the water bath. It is graduated between 20° and 40° C., and this graduation is reproduced upon the face of the index hand. By prolonging the percentage divisions of the top arc diagonally downwards and across the scale plate, as shown in the figure, the percentages may be read of any temperature to within 0·5 per cent. Thus in Fig. 4 the index hand indicates at 40° a little over 1·5 per cent. and at 34° between 1 and 1·5 per cent. The scale may preferably be divided by lines indicating differences of 0·1 per cent., as is shown in one section of the figure. The position and course of the major divisions (at intervals of 0·5 per cent.) were determined by a series of densimetric estimations of vapour aspirated by a suction bellows working under constant conditions.

The maximum percentage of vapour for which the instrument is graduated is 4 per cent. at a temperature of 40° C., but if an available 4 per cent. vapour be deemed inadvisable—as, for instance, when anæsthetising children or as a precautionary measure in inexperienced hands—the water bath may be filled at a lower temperature, say at 30° C., yielding a maximum of 3 per cent. only. The maximum obtainable becomes progressively more limited as the water bath cools, and as the higher percentages are only required in the earlier stages of an operation this offers no disadvantage.

FIG. 4.



Index hand and scale.

In order to avoid agitation of the chloroform which would raise the percentage of vapour,[2] it is necessary to fix the water bath to the table by a clamp provided with the instrument.

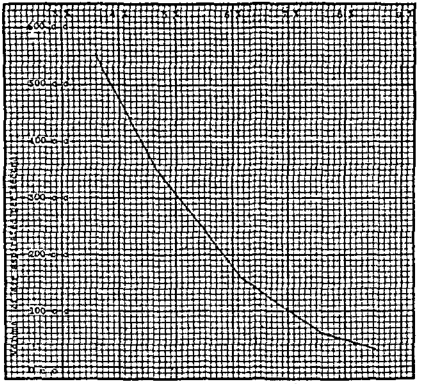
As the chloroform is used up its level falls and this results in a deficiency of about 0·1 per cent. for every half ounce evaporated. This error may in the ordinary course of an operation be neglected, but if for any special reason great accuracy be required the chloroform must be replenished every half hour.

An essential principle of the apparatus is the apparently anomalous one of heating up the chloroform to yield a strong vapour, which is subsequently weakened by dilution with pure air, and it is now necessary to explain the reason of this procedure. The condition imposed of propelling an air current over an evaporating surface by the suction power of human inspiration is far from an ideal one, for the air current takes up a greater or less proportion of vapour according as its passage is slow or rapid, or, in other words, according as a weak or strong draught is induced in accordance with the variable action of the human respiratory pump. The following experiment serves to illustrate this fact. Conditions similar to those of human respiration were reproduced by employing a suction bellows of variable capacity worked by a wheel and crank. The air aperture (*a*) being blocked suction was made by the bellows over the chloroform surface, thus obtaining an undiluted chloroform current. The water bath was filled at 20° C. and the capacity of the bellows was set at 550 cubic centimetres. By turning the bellows wheel a strong intermittent draught was produced and the percentage of vapour taken up was 3·6. When, however, the capacity of the bellows was reduced to 160 cubic centimetres the percentage of [illegible] Fig. 5.) It is seen, therefore, [illegible] roform surface is contra-indicated. However, by drawing a large proportion of the draught through the air aperture (*a*) the current through the chloroform chamber is only a fraction of the whole and is therefore [illegible] current. Now the percentage [illegible] currents does not increase, as [illegible] in the *same proportion* as th[illegible] case of quicker-moving current[illegible] Fig. 5.) The indication, therefore, is to allow only slow currents, which take up a large percentage of vapour, to pass over the chloroform and to dilute them with pure air down to respirable mixtures. If we presume that one-third the total air inspired passes through the chloroform chamber and that two-thirds enter the air inlet it may be deduced from the percentage chart (Fig. 5) that the following mixtures would be obtained with both the apertures open, when the temperature is 20° C.

---

[2] Sharply jarring the apparatus causes a rise in percentage of one quarter of that indicated at the moment on the scale.

FIG. 5.—CHART SHOWING THE PERCENTAGES OF VAPOUR IN THE CHLOROFORM CURRENTS.



[illegible] up [illegible] orm [illegible] ater [illegible] ion [illegible] vapour, a current of half this rate—viz., 275 cubic centi- [illegible] slower currents the increase in value of the percentage of vapour is seen to be much smaller, rather less than one-seventh.

TABLE I.

Draught during aspiration.	Percentage of chloroform in the mixture.
*550 cubic centimetres per second	2·0 per cent.
360 „ „	2·2 „
160 „ „	2·6 „

* Aspiration of 550 cubic centimetres per second results in a current of $\frac{550}{3} = 183$ cubic centimetres per second over the chloroform. Reference to the chart shows that a draught of 183 cubic centimetres per second takes up 6 per cent. of vapour, therefore the resulting mixture is at 2 per cent.

It is seen that the percentages at different rates of draught are approximated but not sufficiently so for clinical purposes; at percentages over 2 the differences would be magnified. Therefore advantage is taken of another natural law to bring the readings into closer approximation. This is the law of the viscous flow of fluids.[3] It will be observed that whilst the pure air enters through a simple thin-walled aperture, the chloroform current flows through a series of tubes and passages, which introduce a measure of resistance to its flow. Now this resistance is of such a nature that it acts relatively more powerfully on slower-moving currents, and thus in the case of weak suction the disproportion between the air current and the chloroform current becomes greater than in the case of strong suction.[3] In this way is induced a greater dilution at low suction pressures than at the higher suction pressures. For example, suppo[illegible] in Table I. (viz., [illegible] becomes, by reason of the viscosity effect, [illegible]nd of two to one (as it is in the case of stronger suction of 550 cubic centimetres per second) then the 160 cubic centimetres will contain 120 cubic centimetres of pure air and 40 cubic centimetres at 8·2 per cent. (see chart) and the resulting mixture will be at 2·05 per cent. instead of 2·6 per cent.[4]

The *following table of tests performed upon the apparatus* serve to demonstrate that the apertures and parts of the apparatus have been so adjusted experimentally that the required effect is in fact obtained.

TABLE II.

Draught per second during aspiration.	Index 2 per cent. Temperature 40°.	Index 4 per cent. Temperature 40°.	Index 2 per cent. Temperature 20°.	Index 3 per cent. Temperature 30°.
550 cubic centimetres	1·9	3·9	2·05	3·0
450 „ „	2·0	4·0	2·05	—
360 „ „	2·1	3·8	2·15	3·0
160 „ „	2·1	3·55	1·9	2·9
60 „ „	—	—	—	1·54

The capacity to which the pump was regulated is the volume of air sucked in a second and is a measure of the strength of draught of air through the apparatus.

When considering the above table in its relation to human respiration it should be noted that a total intake of 550 cubic centimetres of air in a single second is a respiratory effort of more than ordinary force under chloroform anæsthesia and that 160 *cubic centimetres in a second* represents a feeble type of breathing. The suction of 60 cubic centimetres per second *is below the range of human respiration* but is introduced to show the exaggerated viscosity effect during very weak suction. This, of course, is a safeguard in the case of failing respiration.

Variations in the length of pause between the suctions is negligible as a modifying factor and so the above tests definitely show that there occur no substantial deviations from the indicated percentages as a result of variation in respiration and that it is impossible for breathing of a low dynamic type to result in a raised percentage, but that, in fact, under these conditions the percentage tends to fall in value.

At *the expense* only of a slight increase in bulk certain advantages over my earlier pattern of inhaler have been attained. These are chiefly as follows:—

1. A considerable simplification, the only manipulation involved being the adjustment of the index hand.
2. The more perfect blending of the chloroform vapour with the air. The mixture is in consequence more readily respired, there are less tendency to cough and to hold the breath and a diminished liability to excitement.
3. A free entrance and unobstructed passage for the air, causing an absence of any sense of resistance except in the case of very exaggerated breathing.
4. The maintenance of the percentage indicated on the scale for any given position of the index hand, through a greater range of force of suction.
5. The construction of the whole of the apparatus of metal parts to facilitate cleansing and to insure greater durability.

In conclusion, I have to acknowledge with many thanks the facilities provided me by Dr. Vaughan Harley for working at this subject in his laboratory.

Devonshire-street, W.

[illegible] law that *flow through an aperture is* [illegible] square root of the driving pressure, [illegible] tubes, is directly proportional to [illegible]

[4] *As a matter of fact* the obstruction offered to the flow of the chloroform current is insufficient to induce a retardation to the full theoretical extent, otherwise the vapour percentage of a mixture at 160 cubic centimetres per second would be considerably less than 2.

PURULENT OPHTHALMIA AND THE TREATMENT BY ARGYROL.[1]

BY GEORGE E. WHERRY, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

THE remarks now offered to you are founded on 50 cases of purulent ophthalmia which were brought to Addenbrooke's Hospital during a period of five years before 1900. Of these 50 cases 37 were cured, either entirely or without any serious damage. In five cases both eyes were hopelessly lost, and in three of them the sloughing of the cornea was so extensive as to allow of the loss of both crystalline lenses. In the remaining eight there was serious impairment of vision of one or both eyes resulting in corneal opacities, partial staphyloma, pyramidal cataracts, and other lesions. Two of the patients affected were twins, and there was one instance of the disease happening twice in the same family. Six died during or shortly after treatment for syphilis, meningitis, and other maladies. One case of arthritis occurred which possibly was of the nature of so-called gonorrhœal rheumatism, but the gonococcus was not looked for in the fluid effusions of the joint. In one case a purulent discharge from the nose made one wonder that this event did not happen more frequently, but the nasal passages are very rarely infected. Several cases of syphilitic "snuffles" were noted. With one exception both eyes were affected, but in several one eye was infected later than the other, and in these probably the contagious matter was introduced, not at birth but later by fingers or towels. It usually happens that the infant is brought to the hospital by a neighbour, the mother being still in bed or not yet strong enough for the journey. In 31 cases no medical man was in attendance during the confinement; several children were illegitimate With regard to the nurses employed, one, Nurse E , had been in attendance on the mothers of eight infants, Nurse C. on five, Nurse M. on four, but sometimes a neighbour gave help at the labour and neither nurse nor medical man was present.

The amount of damage done in the cases with partial recovery is not easy to estimate, and the ultimate result is very difficult to forecast because an apparently slight lesion may cause great impairment of vision and an apparently large mischief may clear away wonderfully. An important consideration to bear in mind is that the cornea has its own rate of growth and is peculiar in that regard, attaining its full surface area at five years old. So that we look through the same sized windows at five as we do at 40 years. The cheerful point is that clear cornea, except in perforated cases, *grows* while the surface area of the opacity or scar diminishes.

It is well to understand that very serious consequences may follow a purulent conjunctivitis which is not gonorrhœal. Not long ago I saw an example in an infant with one eye only affected in an otherwise healthy female child. There was a resulting opacity, now nearly clear, but both nystagmus and slight squint have appeared, so that though the cornea clears the case has still a serious aspect. About the mode of contagion: of course, usually the poison was obtained from the mother's passages during the birth of the child. Several of the cases had been bathed with milk, most often the mother's milk. In this connexion I may mention the disgusting practice, among alien populations about Smithfield, of bathing the child's eyes with the mother's urine. The mode of onset also suggested that some cases had been inoculated later than birth.

It is curious to note that in gonorrhœal ophthalmia of adults the right eye is more often affected than the left, no doubt from the more free use of the right hand in self-inoculation; also that a large number of cases give a history of a pre-existing blepharitis as pointed out by Mr. E Nettleship, which would make the tendency to a fidgety rubbing of the eyelids and thus render inoculation more probable Some are of opinion that the blepharitis renders the conjunctiva more vulnerable to the gonococcus poison. Certainly the conjunctiva defends itself in an admirable way against all microbes except a very few and suppuration cannot be established easily in the conjunctival sac so as to be kept up without these special cocci. This is well seen in the old cases of pannus which were sometimes treated with jequirity seeds to excite suppuration, for it was found very difficult without gonorrhœal pus to excite purulent inflammation sufficient to cure the pannus, and the gonorrhœal pus was used occasionally with good success and permanent cure as to the pannus and trachoma.

But the bacteriology of this subject is apart from the purpose of this paper. A word as to the prevention of the disease and of its terrible results. 1. In order to get the cases earlier papers of warning have been printed for me and during the past 15 years have been given to suitable distributors, relieving officers, and others. 2. It was useless to appeal to those in charge of the charity which employs the nurses in the poor districts. So soon as it was discovered that this disorder often depended upon "something improper" the ladies would not stir in the affair. To a few nurses I have given bottles of drops to use in suitable cases of newborn children, especially when the mothers have vaginal discharge, but I have no control over these nurses and no supervision whatever over cases in which there is neither medical man nor nurse to attend at the labour. Of this I am assured, that if nurses were armed with argyrol drops the disease would be greatly checked.

Knowledge comes but wisdom lingers. We have known of this contagious malady for many years. The discovery of the gonococcus has not done much to diminish its ravages. Our knowledge is greater but we are not yet wise enough to stamp out the disease and it appears to me a matter for sad reflection that this diabolical microbic malady is as prevalent in this district as it was 20 years ago In 1885 Sir William Bowman stated before the Local Government Board that 30 per cent. of the inmates of the blind asylums had lost their sight in this way and there were at least 7000 persons in the United Kingdom blind from this cause and to these an equal number might be added to represent those suffering from the effects of the malady in less severe forms.

These cases on which the foregoing remarks are founded were observed before the use of argyrol. A few words now as to the use of this remedy which I have tried in a large number of cases. It is a silver salt; as such it is used in cases when nitrate of silver would otherwise be suitably applied The solution as standardised at the factory in Philadelphia is diluted to make a 50 per cent. or 25 per cent. for drops of usual strengths. It does not cause pain, it is not followed by irritation of the lids, and the staining of chocolate-brown washes off the lids or cheek without permanent mark and weak corrosive sublimate takes the stain off quickly. It has its greatest value in checking suppuration from the conjunctiva and in some most unpromising cases it has proved to be the best remedy.

At the extremes of life in infancy and old age, with the eye during growth or the eye during degeneration, the treatment of disorders needs watchfulness and special care. It is most useful in purulent ophthalmia and while not wishing to discredit old and tried remedies I must speak well of argyrol. Frequent ablutions of the conjunctival sacs and the careful use of the irrigation-can and swabs by a nurse of experience are as much needed with argyrol as with the old drops of protargol or silver nitrate.

In the hospital during the past 12 months almost the only case of conjunctival suppuration which has not been successfully treated with argyrol is the following. The patient was a female child, aged six years, with profuse suppuration filling the conjunctival sacs, causing dusky red swelling of the lids and threatening destruction of the cornea of both eyes. Argyrol drops, nitrate of silver, and other remedies all failed. Thick polypus like granulations lined the lids. The child had a sore-throat and both in the exudations from the throat and in the pus from the conjunctiva were found the Klebs Löffler bacilli. The pus formation had continued during ten days, no remedy making any impression. As soon as 12,000 units of antidiphtheritic serum were injected this treatment cleared the eyes of discharges and no further injection of serum was needed. Except that an abscess formed in the neck there was a wonderfully complete recovery in a few days both of the eyes and health generally. Slight nebulous cornea alone remained. It was interesting to note in this case that there was no response to the remedies used until the antitoxin had been injected. Another point of interest is that there was during ten days thick pus discharged from the conjunctival linings and not the usual membranous exudation of diphtheria.

Next, to relate briefly the case of a woman, over 70 years of age, who had lupus of the face for 30 years. The end of the nose and portions of the face were destroyed and active tuberculous disease affecting both eyes had caused a hypopyon ulcer in one eye. Argyrol drops used every eight hours proved successful in causing complete absorption of the pus in the anterior chamber, relief from pain, and as much improvement in the general condition of the eye as could be expected. It is well to note in this place that the argyrol drops are carried by the tears into the nose and in this patient the nostrils affected by the lupus would have shown any results of irritation if such had chanced, but though the raw surfaces of the ulcerated nostrils were stained by the fluid it was rather useful than otherwise as an application to the lupus sores.

---

[1] A paper read before the Cambridge Medical Society on April 7th, 1905.

Like an embarrassed sportsman who puts up too many hares I fear to give you too many details and in giving you these remarks, leaving out much to make my paper suggestive rather than exhaustive, there are plenty of gaps left for others to observe and to report upon. You will see that argyrol puts in a great claim for your favourable regard both in the treatment and prevention of purulent ophthalmia.

Cambridge.

IS MAN POLTOPHAGIC OR PSOMOPHAGIC?

BY HUBERT HIGGINS, M.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,
LATE DEMONSTRATOR OF ANATOMY AT THE UNIVERSITY OF CAMBRIDGE AND ASSISTANT SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

PART II.[1]—THE PRACTICE OF POLTOPHAGY.

IN Part I. I stated a case for poltophagy *versus* psomophagy in man, relying for my main argument on the fact that structure is crystallised function. When using such a point as this it is almost irresistible not to carry it further into the psychical equipment for the choice of foods and the indications necessary to determine its quality and quantity. To wild animals it would seem to be as necessary to be able to adjust their food to their needs as that of obtaining water or oxygen, for the penalty of inefficiency is generally death. What conditions have arisen, it may be asked, that the existence of such a faculty should even be questioned in man? What compensation has civilisation provided in its place? Mr. Horace Fletcher put this point to me with admirable clearness and brevity in 1901 by telling me "that if one insalivated and masticated one's food and ate what one liked the rest took care of itself." Three years' experience has lead me to have a growing conviction of the substantial truth of Mr Fletcher's contention. This apparently simple but really difficult proposition is the one that this paper mainly deals with, because it is an absolutely essential part of any intelligent appreciation of the phenomena observed during the practice of poltophagy. To express this psychical equipment in the case of animals one makes use of that much-abused term "instinct"; in the case of man one speaks of appetite and taste. Appetite has become a much less vague term in consequence of the labours of Pawlow. It is to be hoped that taste will yield up its secrets to the determined assaults of Dr. Kiesow of Turin.

I have first dealt with appetite, then taste with points dealing with foods, afterwards I have briefly considered the acquirement of the habit of poltophagy, also changes in the fæces and the large intestine.

[illegible]

this passionate desire for eating that unerring and untiring nature has linked the seeking and finding of food with the commencement of the work of digestion. That this factor, which we have now so carefully analysed, stands in closest relation with a phenomenon of daily life—namely, appetite—may easily be predicted. That agency which is so important to life and so full of mystery to science becomes at length incorporated into flesh and blood, transformed from a subjective sensation into a concrete factor of the physiological laboratory. We are justified in saying that appetite is the first and mightiest exciter of the secretory nerves of the stomach."

It would be impossible to have any conception of the nature of poltophagy without looking on appetite as the most essential part of the phenomena presented by its practice. It is important to tell those commencing the practice that they should on no account eat without appetite and that they should cease as soon as appetite ceases. It will be useful to consider appetite from the following points of view:—

(*a*) *Variations in appetite.*—Appetite varies from a well-defined and decided preference for certain foods to an ill-defined general hunger, or the condition known as a poor appetite. Speaking generally, an individual is at his best with a decided appetite for one or more of the groups of foods described below.

(*b*) *The cessation of appetite.*—The end-point of a meal is very decided and well marked in poltophagy. It is quite exceptional to find that undecided end-point so well shown at the end of dinner, during the dessert stage with its sweets, fruit, biscuits, &c.

(*c*) *The frequency of meals.*—At variable periods of time after commencing poltophagy it may be said that in many people leading an ordinary sedentary life there is only one good appetite in the day and [illegible] meal, somewhere about mid da[illegible] any, is from five to eight in the [illegible] not to suggest to patients that their appetite is going to be immediately changed; that, for instance, they will not require breakfast. It is usually very much better for them to indulge their appetite. One patient did not omit breakfast for about two years after starting poltophagy, another was nearly a year. Abnormal frequency of meals soon ceases if patience is exercised. I recall one patient who commenced with five or six meals a day; after six weeks' treatment he had only one.

(*d*) *The absence of appetite.*—In the absence of appetite a patient must be encouraged not to eat even for two or three days. Good appetite and good digestion are generally the reward. In one case where there was an absence of appetite for periods of two, three, and four days with abstention from food there was decided hyperchlorydia at the same time.

(*e*) *Appetite and mastication.*—The question has often occurred to me whether in those commencing the practice the unaccustomed use of the muscles might not be a potent factor in producing the immediate diminution of appetite almost invariably noted.

(*f*) *Hunger.*—An interesting feature of the practice is that there is none of that uncomfortable faintness when a meal is passed over. On occasions when food is not obtainable for two or more hours over the accustomed time the appetite remains but without any discomfort; it might be described as postponed.

2. *Of taste and preferences for foods.*—An attractive feature [illegible] *eferred (the food* [illegible] st suitable. This [illegible] nd appetite even in those who are in process of regeneration. This idea is at first somewhat difficult to grasp, but it must be understood that a certain amount of interpretation of preference is necessary. For instance, a great fondness for the juice of oranges or grapes was replaced in its turn by a wish for salads. This was interpretated to show a want for vegetable salts. A solution of these salts was prepared by boiling finely divided vegetables in milk and was found to replace preferences for fruit and salad in many other cases besides the one in point. It will be convenient to deal with the question of preferences under the following heads.

(*a*) *Vegetable salts.*—Fruit, vegetables, &c., are called for in most cases. It is important to take the greatest care in obtaining the purest food and that it should be cooked in the best possible way

(*b*) *Fats.*—It is very remarkable that without exception all cases take a large amount of fat (about 100 to 150 grammes a day). This amount was taken by a patient who was losing two kilogrammes a week in weight When this appetite shows itself in a case it is better to provide, as well as the best butter, freshly separated cream, the purest form in which fat can be obtained. The quantity eaten is by no means constant, varying from day to day, while some days hardly any at all is required.

(*c*) *Starches, dextrins, sugars.*—It is noticed in some cases that the appetite for starch is replaced by a preference for dextrins, prepared either by frying bread or potatoes in butter or oil, or else thoroughly toasting bread. Dextrins, it must be remembered, are pepsinogens (Schiff). This may account for the popularity of the many patent foods now manufactured by the treatment of cereals by superheated steam. Starch itself is called for in the form of rice, bread, or potatoes. Preferences between these forms of starch curiously enough seem to be distinct.

---

[1] Part I. was published in THE LANCET of May 20th, 1905, p. 1334.

(*d*) *Proteids.*—The appetite for this form of food is the least distinct (except in the case of meat). The want of proteid generally shows itself in the form of faintness or a condition of nervousness and irritability. It is certainly the least defined of the preferences (the reason possibly being that it is the tasteless ingredient of so many foods). In the case of meat, on the contrary, there is a very distinct and unmistakable want which occurs after physical strain, when the individual is not fit, or after such mental strain as travelling. A plausible explanation of this phenomenon is afforded by the work of Dr. Sloss of Brussels who showed that tetanised muscle gives off NH_3 instead of CO_2. Might not that fierce and unmistakable appetite for meat show that in consequence of merely temporary or more permanent degenerative changes there is need of proteid on the part of the muscle tissue?

(*e*) *Fluids.*—*Water:* Thirst often presents very interesting phenomena. There is a condition in which the body tends to store water; for instance, on days when an unusual amount of meat is taken there may be a well-marked thirst with an *increased intake of water. This excess water may be lost in* a few days, curiously enough accompanied by the loss (at least in one patient in whom analyses were being made) of as much as 16·5 grammes of NaCl in the day. In the early stages, thirst as well as the amount of urine, tends to be variable. In later stages no water is as a rule called for till midday, the urine gets low in amount, as in the case of Professor Chittenden.[2] The case of Professor Mendel, on the contrary,[3] resembles an early case in which the body makes use of more water. In the first instance, I take it, that economy is shown in the case of water as well as in the other ingredients of the ingesta. Another point is that the body supports a loss of water during exercise with much less urgent thirst. Another interesting observation has been made that, during the conditions of water storage, there is a decidedly increased blood pressure which diminishes when the water is lost. Might not the cause of high blood pressure be that when there is an increased quantity of water stored in the tissues, it exercises a pressure on the capillaries and so increases the blood pressure. *Alcohol:* A craving for alcohol has been known gradually to disappear during the practice of poltophagy. A preference for alcohol is shown when there is exhaustion due to over-exercise or in cold weather, but only in small quantities. The association found in the study of preferences of meat, tea, coffee, and alcohol, as concomitants of exhaustion, throws a suggestive light on the craving for stimulants. Might it not indicate a need of a degenerate body, and if this is found to be the explanation would not the treatment of such conditions be to look at them, not as a morbid manifestation of the brain, but as an indication of a physical state of degeneration? The most distinctly recognised preferences are fats, meats, vegetable salts, and starches (except in cases that prefer dextrins). Sugars in the form of sweets, pastry, bon-bons, and cakes belong to a group of preferences that, generally speaking, appear to give less subsequent satisfaction than do the stronger preferences; the end-point is not so distinct in sugars.

3. *The acquirement of poltophagy.*—In teaching suitable cases to practise this habit it is essential to bear in mind the nature of the complexity of the unconscious series of efferent and afferent impulses, movements, and secretions. In the process, psychical, ordinary, and special sensations, complex coördinated impulses to the muscles of the cheeks, the lips, the tongue, the jaw, the soft palate, and the pharynx all take a part that has been allotted to them in the long process of evolution. It must be remembered as well that the methods of the ingestion of food take the first rank in the order of the vital processes of the body. I will briefly state the means that experience has shown are most likely to be used in practice.

(*a*) *By counting the number of mastications.*—Interest has been taken in the number of movements of the jaw made in the disposal of food. This shows remarkable variations, even in the same individual; they seem to depend on many different causes. Recently I observed that a kangaroo gave over 80 mastications to a piece of bread. In a case that digested starch with difficulty it was often over 150 (see above, Starches). Mr. Gladstone, it is said, was in the habit of attributing his strength to masticating his food from 30 to 35 times. An inquiring friend of mine had the curiosity to count the number at a dinner at Cambridge from the spectators' gallery and found that it was more often from 60 to 70, so that in reality Mr. Gladstone was more poltophagic than he knew. He did not count his mastications, therein showing his habitual wisdom. I feel that it cannot be too much emphasised that there are numbers of cases in which attention to automatic acts is very decidedly harmful. So that this method, unless especially adaptable to certain cases, should be used with caution.

(*b*) *By hyper-mastication* (conscious retention of the food a long time in the mouth).—The objection to this practice is that it must interfere with the natural series of events by the continual inhibitory action of the will. It may be effected by pressing the tongue against the hard palate at its hinder part. N.B.—In the case of the digestion of starches this will cause the inhibition of the action of the ptyalin when part of the starch has been converted into dextrose.

(*c*) *Masticating until taste is absent.*—This, I take it, is *making a sensation (of which one takes other cognisance* than the agreeable one of pleasing the palate) mark the end-point of an unconscious and automatic series of events. Personally, I feel that the process of mastication and deglutition is complete in itself and so complicated that it cannot be interfered with by any arbitrary divisions of its periods by the will, except to its detriment. A useful plan that has stood the test of experience is to direct patients to commence by masticating one or two teaspoonsful of flaked wheat or else one of the many preparations of oatmeal once or twice in the day before meals. Afterwards the patients should be instructed in as much as is thought advisable of the nature of mastication, &c., and in understanding that there is only one thing which it is important for him to remember and that is not to push the food backwards against the soft palate with the tongue. Any symptom of revolt against the practice is, I believe, an indication of rest for a day or two.

4. *Considerations involving body habit.*—No one in the practice of the medical profession is without a great respect for habit and few cannot recall startling events following on too abrupt changes. It seems to make little difference whether it is a change from a bad to a good habit or *vice versâ*. The result of the exceptional opportunities that I have had of observing cases commencing and actually practising poltophagy is to have a far greater respect for what is called body habit. I recall one patient in particular who commenced the practice during hard work and who went on very well for two or three weeks, showing all the usual symptoms of improvement in health, increased power of work, &c. At the end of three weeks he lost weight and had his power of work seriously interfered with for some 18 months. In cases in which there is habitual strain or chronic disease, especially in nervous cases, as much care as possible should be taken in the early stages of the treatment. The ideal conditions would be an open-air life in the best climate available, with a possibility of perfect rest. Weight and the general condition require, of course, careful watching. The precautions to be taken with the more healthy must vary with individuals, but even in these cases care must be taken. These remarks must not be taken in any alarmist spirit but in such an early stage of a practice, which, though of the highest value for the treatment of chronic disease, is in its infancy from the point of view of practical experience, it is important to emphasise the difficulties of the treatment. As long as it is borne in mind that the practice involves a complete change of body habit it will, I feel sure, be found to present few difficulties in practice with the employment of the ordinary precautions that medical experience would suggest.

5. *Changes in the fæces.*—There is a very marked decrease in the weight of the fæces. The most conspicuous feature, however, is the absence of the ordinary fæcal odour. The form and character of the fæces may be classified as follows. (*a*) Mouldings of the sacculi of the large intestine which are of about the size of a hazel nut, smooth, and occasionally faceted. Their colour is occasionally dark green, more frequently dark brown, less frequently a lighter brown. There is a clean fracture, showing a marked dryness. They are usually covered with a thin coating of mucus. (*b*) Adherent forms of (*a*). The adherent masses are obviously formed by the adhesions of the sacculated mouldings; they

---

[2] Physiological Economy in Nutrition, pp. 24-29.

[3] Op. cit., pp. 53-59.

are usually mixed with the isolated form of moulding described above. Their colour is generally lighter than (*a*) and they are usually a little less hard. (*c*) Rectal mouldings with indications of the sacculi mouldings. This form varies from that of an ordinary rectal moulding marked with wavy lines, to distinct and unmistakeable prominences showing the mouldings of the sacculi of the large intestine. The colour has a tendency to be lighter and the material to be of a softer consistency. (*d*) An ordinary unmarked rectal moulding which has a tendency to be of a lighter colour and less firm in consistency. (*e*) An unformed soft motion. The most common form is that of the isolated mouldings of the sacculi, the other forms being exceptional.

A very interesting form of evacuation is seen when there is intestinal irritation from any cause, when there is occasionally seen a series, as it were, of the forms described above, commencing with the isolated mouldings of the sacculi and ending with the soft unformed material. This might be thought to indicate that the difference in form merely shows the length of stay in the intestinal canal. In several cases the habitual length of time between ingestion and egestion (shown by taking charcoal) has been found to be about three or five days. There is not a daily evacuation in the early stages of poltophagy; there may be intervals of from one to two or as many as three or four days.

6. *Changes in the large intestine.*—All those who have had experience in the observation of subjects in the dissecting-room, &c., cannot fail to have noticed the large size of the sigmoid flexure commonly found; sometimes it is enormous. In one case in which the bowel had been large it is now very much smaller and muscular (more distinctly felt); the mouldings described above can be felt *in situ*. In this case there had been a period of trouble that was due to the accumulation of fæces in the neighbourhood of the cæcum. The question naturally occurs to one that in the event of a case having a large sigmoid flexure there might be some difficulty from atony, the bowel failing to deal with the diminished quantity of fæces. This may also explain the long intervals of time between the evacuations as noted above. The habitual state of the fæces can, I think, be an indication of the condition of the bowel, if not an indication of the state of the muscular coats, at any rate of the size of its lumen.

7. *Changes produced by poltophagy.*—The chief changes are: as regards appetite it tends to become well defined at the commencement of a meal, as well as to cease as definitely at the end. There is a marked increase of pleasure in eating. The taste for simple food becomes more pronounced, preferences are more defined (if care be taken to study and to indulge them). The fæces are lessened in amount and are odourless; on those occasions in which odour is present there is marked malaise and discomfort. The large intestine gets smaller and the fæces tend to remain a longer time in the bowel. In all cases it can be said that there is an extraordinary change in the general health, much more of the joy of living, increased power of work, and freedom from the infinitely troublesome concomitants of chronic disease. It can be safely said that practically without exception there has been a remarkable improvement.

8. *Conclusion.*—In this paper I have brought together a few observations the result of some three years' experience in what one must feel is almost a new branch of knowledge. The opinions expressed here are of the order of those ideas of so provisional a character that they are subject to frequent alterations as experience is gained, some points being strengthened, others abandoned, a state of affairs characteristic of such an inquiry. There are many points, and especially those of the nature of speculations, it would have been wiser perhaps to have omitted. They are brought forward as suggestions and hints, the most speculative of which even may prove to be useful to those who may be tempted to pursue the same line of inquiry. The conviction grows that the careful study of the psychical preferences of the body, whether degenerating, regenerating, or healthy (?), will reveal unsuspectedly important principles in the science
shows the great need of s
state of health and fitness
for instance, to compare a [illegible]
not. One of the greatest services that Professor Chittenden has rendered in his work on the economy of nutrition is to have used as many means as he could to measure the condition of the subject he was observing. He was singularly fortunate in that Dr. Anderson, holding the unique position of physiologist to a gymnasium, was able to give him his assistance. It will be obvious to those who read Dr. Anderson's able reports that he has made full use of his opportunities for observation. It is not too much to say that there is no problem among those vexed questions of sociology which does not need the quieting influence of scientific measurement. Not only the unhealthy and inefficient but the criminal, the pauper, &c., requires some sort of measurement before they are condemned to the curious means of regeneration used in our prisons and workhouses. Such work as that of Professor Chittenden points the way along which one can hope to find that the long martyrdom of man to vagueness and ignorance will give way to a scientific knowledge of regeneration and humaniculture.

I cannot terminate this paper without far too short a reference to the history of Mr. Fletcher's labours in this field of knowledge. For years he persisted in advancing his plea for investigation to almost anyone who would listen to him and it was not until he met Mr. van Someren that he had a sympathetic and intelligent hearing. The latter wrote a striking and interesting paper, which was read at the meeting of the British Medical Association, entitled "Was Luigi Cornaro Right?" The paper was afterwards read at the International Congress of Physiology at Turin. The result of their long visit to Cambridge was to excite an interest in the question at Yale, where Professor Chittenden carried out the work previously referred to. To both these gentlemen I owe a very special debt of gratitude; to Mr. Fletcher for the suggestion that has been the means of restoring my health, and to both of them for giving me the opportunity of having the experience which has enabled me to write this paper. If there is any difference of opinion on questions of practice between these gentlemen and myself I am sure that both of them have the same hope which I have—that the further investigation of these phenomena should be undertaken in their entirety by those organisations of science where alone it is possible to carry on so wide and comprehensive an inquiry to its logical conclusion.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TWO CASES OF IDIOPATHIC GENERAL CATARACT IN CHILDREN CLOSELY RELATED.

BY T. HUNTER, M.A., B.SC., M.B., CH.B. GLASG.,
CAPTAIN, I.M.S.; CIVIL SURGEON.

THESE two cases were brought together to the out patient dispensary at Fatehgarh, United Provinces, India. They were first cousins, the father of one child and the mother of the other being brother and sister. The home of one child was in Benares and that of the other in Amritsar, Punjab. They were accompanied to the dispensary by the father of the boy and the grandfather of both. These two men were strong healthy individuals. The grandfather had an incipient cataract in his left eye but no other defect or disease could be elicited on inquiry into the family histories. The people were respectable, well-to-do Hindus of the literary caste.

One of the patients was a boy, aged 22 months. He was a strong, healthy, and intelligent child, and showed no sign of rickets. He had a complete cataract in his right eye, pearly-white in appearance, and a slight haziness of the lens in the left eye. The defect in the right eye had been noticed by his friends for about one and a half months. Examination with the ophthalmoscope showed that it was mature. Both pupils reacted normally to light

The other patient wa
was a healthy, intelligen
To the naked eye the pupil [illegible]
but on examination with the ophthalmoscope glittering sectors were noted. The child was able to count fingers with this eye. The defect had been first noticed by the child's parents about 12 months prior to examination. Both

pupils reacted normally to light. The right eye was normal in appearance, emmetropic, and had a healthy fundus.

Fatehgarh, United Provinces, India.

A CASE OF SUPPURATION OF THE EYELID AND SUPRA-ORBITAL REGION FOLLOWING CAUTERISATION OF THE NASAL REGIONS.

By W. R. H. STEWART, F.R.C.S. EDIN., M.R.C.S. ENG.,
SURGEON TO THE EAR AND THROAT DEPARTMENT, GREAT NORTHERN CENTRAL HOSPITAL; CONSULTING SURGEON TO THE LONDON THROAT HOSPITAL, ETC.

THE patient, a boy, aged 16 years, consulted me on Friday, Jan. 6th, for nasal obstruction. Both inferior turbinates had their mucous membranes hypertrophied. I cauterised the right side and sent him home with instructions to keep quiet indoors. These instructions he carried out as follows. The rest of that day (Friday) he spent walking about London. On Saturday he went shopping in the morning and to a theatre in the afternoon. On Sunday he went to church in the morning and visiting in the afternoon. On Monday morning he felt pain in the eyebrow; he, however, drove to Putney for a dance that evening. On Tuesday, notwithstanding pain, he again went to the theatre. On Wednesday he returned home and went to bed. On Friday he came to me—a bitter east wind was blowing—and I found the supra-orbital region and eyelid swollen and œdematous. The following week I freely incised both places and found a large amount of pus. After this the boy did well. Never having come across a similar sequel I think it worth recording as emphasising the necessity of care, even after a simple cauterisation, more especially in bad weather.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL.

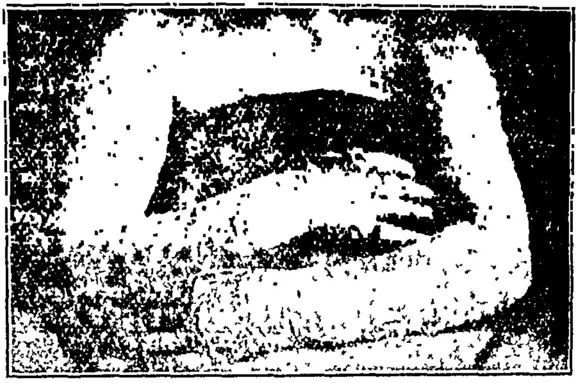
A CASE OF PSORIASIS DIFFUSA.

(Under the care of Dr. WHEELTON HIND.)

FOR the notes of the case we are indebted to Mr. Eric E. Young, house surgeon.

The patient, a female aged 18 years, was admitted to the North Staffordshire Infirmary on March 10th, 1905, under the care of Dr. Wheelton Hind, suffering from psoriasis diffusa. A year previously she had first noticed an eruption commencing on the forearms and the legs and this had rapidly spread. She attended the out-patient department for many months with little or no benefit, various drugs and applications being employed. At one time it was thought to be a case of specific disease but a long course of mercury and iodide of potassium produced no change in the condition. As she steadily got worse and the eruption continued to spread without showing any signs of disappearing she was admitted to the hospital and the first photograph shows the condition of her arms and hands. The photographs of the legs and trunk were not a success and therefore are not published. The face was not affected though the patient stated that she had had a scaly eruption on the cheeks. The nails also were normal. The whole of the arms, the forearms, the hands and fingers, the thighs, the legs, and the dorsum of the feet were covered with dense silvery scales, both the flexor and extensor surfaces being equally affected. Great pain was complained of in the hands owing to the cracking and excoriation of the skin and she could not even hold a pen within the fingers. Numerous patches of variable size were also present on the anterior and posterior aspects of the abdomen and thorax. The temperature was normal and the patient's general health did not seem to be in the least affected.

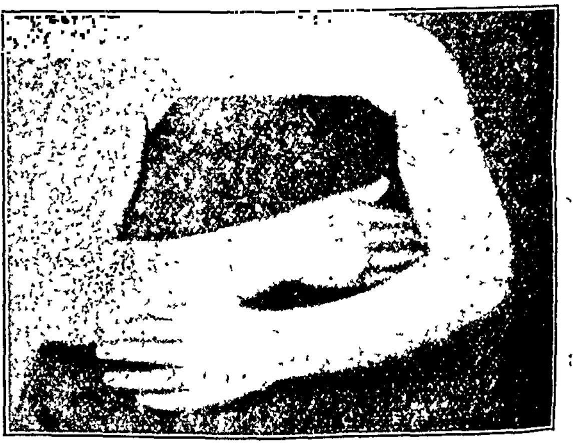
FIG. 1.



Condition of patient before treatment.

Treatment was carried out in the following manner. A daily morning bath was given for half an hour in water boiled with bran and at a temperature of 95° F. After the bath the body was rubbed with salicylic acid ointment (10 per cent.). Two grains of thyroid extract in the form of tabloids were given night and morning, and the patient was ordered a mixture containing four minims of arsenical solution and 20 grains of citrate of potassium three times a day. The dose of arsenical solution was quickly increased to ten minims and in a week the amount of the thyroid extract was increased to five grains night and morning. The second photograph, taken ten days later, shows very markedly the effects of the treatment. The patient has now left the hospital but has been ordered a course of treatment by thyroid extract and arsenic.

FIG. 2.



Condition of patient after treatment.

Remarks by Mr. YOUNG.—The foregoing case is, to my mind, of sufficient interest to place on record if only because it shows how a patient who has been attending the out-patient department of a large hospital for some time may occasionally derive much benefit from a short period of proper and efficient treatment when admitted as an in-patient. I must express my gratitude to Dr. Hind for so kindly according me his permission to publish the notes and to reproduce the photographs of the case.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

A CASE OF ANTHRAX SUCCESSFULLY TREATED WITH SCLAVO'S SERUM.

(Under the care of Mr. J. LIONEL STRETTON.)

THE patient, a female, aged 17 years, was sent to the Kidderminster Infirmary and Children's Hospital by Mr. H. L.

Miles on April 24th, suffering from a well-marked malignant pustule situated in front of the right ear. She was employed as a spinner and she stated that she remembered scratching her ear with a hairpin a week previously. Two days later she felt an irritable papule which gradually increased in size. The pustule involved the lobule of the ear, the anterior wall of the auditory canal, and the adjacent portion of the cheek. There was a considerable amount of œdema and swelling extending forwards to the malar region and downwards into the neck. Her general condition was satisfactory. Examination of the serum from some of the surrounding vesicles showed large quantities of anthrax-like bacilli. She was immediately admitted and 40 cubic centimetres of Sclavo's serum were injected above her abdomen. There were no local reaction and very little general effect, her highest temperature (100° F.) being reached in 50 hours. The swelling gradually subsided and she was discharged cured in six days.

It was intended to save some tubes of serum for cultivation experiments but this was unfortunately forgotten. On the second day some tubes were taken and were then sent to the Clinical Research Association. The report upon them was as follows: "On direct examination no anthrax bacilli could be found. Media were inoculated and cultures containing the streptococcus pyogenes, staphylococcus pyogenes albus and aureus, and some rod-shaped organisms were obtained, but no colonies of the bacillus anthracis were present."

Remarks by Mr. STRETTON.—This is the fifth case treated in this country by Sclavo's serum without operation and the fourth successful one. I have already reported a case treated by the combined method of excision and inoculation and I am still of opinion that this method ought to be adopted in all cases where it is possible freely to excise the pustule. In this case it was quite impossible and I therefore felt fully justified in using the serum alone. The case was certainly a bad one and from my experience I should have expected a fatal result. How far this was averted by the use of the serum it is impossible to say but the results so far are certainly encouraging. It is interesting to note that no bacilli were found in the serum which was taken 36 hours after the injection, although it was previously teeming with them.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Morbid Anatomy of Myasthenia Gravis.—Morbid Growth from Angora Ewe.—True Hermaphroditism in a Leghorn Fowl.—Congenital Malformation of Lower Extremities.

A MEETING of this society was held on May 16th, Mr. RICKMAN J. GODLEE, the Vice-President, being in the chair.

Dr. E. FARQUHAR BUZZARD read a paper on, and showed specimens illustrative of, the Morbid Anatomy of Myasthenia Gravis. The central and peripheral nervous system in cases of this disease had been often examined by a number of competent observers but had not shown constant changes. During the last few years attention had been drawn to the occurrence of hypertrophy or tumours of the thymus gland associated, in certain cases, with deposits of lymphoid cells in the skeletal muscles, by Weigert, Goldflam, Hun, Link, and others. Dr. Buzzard had examined post mortem five cases of myasthenia, in three of which there were no marked naked eye changes. In one case, that of a woman, aged 29 years, there was a [illegible] grammes and having the [illegible] of the normal gland in [illegible] ...sented the features of a simple hypertrophy and was noticeably free from eosinophile cells, large numbers of which are generally found in the enlarged glands of children. In another case there was found a large mass in the anterior mediastinum in the position of the [illegible] appearance. [illegible] growth and [illegible] lower part [illegible] fluid. Secti [illegible] connective tissue between which were large masses of small round cells and very few definite concentric corpuscles. The walls of the cystic portion showed similar features but contained occasional Hassall bodies. In the three other cases the thymic remains did not present any features which could be considered abnormal. The central and peripheral nervous system was carefully examined in all cases but no constant or important changes were detected. The investigation of the muscles and of the visceral organs yielded positive results of a constant kind in all five patients. The most important and characteristic of these was the presence of small foci of cells resembling lymphocytes scattered irregularly between the cells of a glandular organ. The term "lymphorrhage" might be applied to these collections both on account of the characters of the cells of which they were composed and because their general appearance was suggestive of a capillary hæmorrhage with the distinction that the cells were not red blood corpuscles. A small empty capillary vessel lined by a single layer of endothelium was sometimes observed in the neighbourhood of these lymphorrhages. The latter had been found in a smaller or larger number of the muscles of each case but, in some instances, only after a prolonged search. The ocular muscles had been most fruitful in the three cases in which they had been examined. The only other changes in the muscles were presented by a few fibres which had become swollen and rounded, more hyaline or granular in appearance, and often showing a tendency to stain a paler hue with eosin or fuchsin. Lymphorrhages were found also in the liver, the adrenal bodies, the thyroid gland, and in the cardiac muscle, and in one instance a similar condition was detected in a posterior spinal root ganglion. In the glandular organs the cellular deposits were frequently unaccompanied by any other changes, but in a few instances, where the lymphorrhage was of larger size, the neighbouring gland cells had undergone degeneration or destruction. As a result of the investigation it was evident that the thymus tumours or thymus hypertrophy were not constant characteristics and that they must not be regarded as the origin of the other changes but rather as associated phenomena of frequent occurrence and great interest. The fact that in five consecutive cases similar microscopical changes had been found in the muscles and other organs went a long way towards establishing a definite morbid anatomy for the disease. The objection to that view, which might be advanced on the ground that previous observers had failed to describe these changes, was met by the very extensive search required to establish their presence and by the well-known truth that what was not particularly looked for was frequently overlooked. The absence of blood changes and of any alteration in the general lymphatic system rendered the origin of the lymphocytic deposits very obscure and little light could be thrown on the relation of the morbid changes to the clinical features of the disease.

Dr. W. E. DE KORTÉ showed a Morbid Growth obtained from the Anus of an Angora Ewe. The Angora goat was an importation into South Africa where this disease occurred and it was remarkable that the aboriginal goat of the country, the so-called Cape goat, was practically immune to this disease. The ewe was nearly always affected, though rarely the ram was also attacked, and then the penis was said to be the site of the disease. The apparent immunity of the male might, however, be due to their relatively small number in a flock compared to the females. The disease rarely, if ever, affected animals under two years of age, the age incidence being from two to four years. Particular strains of ewes appeared to be more susceptible than others, those having a peculiar whitish appearance about the anus, roots of the horns, eyes, and nostrils being particularly liable to the disease. The disease started as a small wart which gradually spread and the whole of the anus might become involved. It soon, however, underwent ulceration and presented a raw fungating mass which bled readily and emitted a horrible fœtor and became the abode of maggots and of bush lice. A further point of interest was the incurability of the disease; all sorts of caustics, including arsenious acid, had been tried without avail and after lingering on for some months the affected animal died in a cachectic condition. So well was the mortal character of the disease recognised that careful farmers invariably cut the throats of the diseased ewes as soon as it was detected and this was done not only on humanitarian grounds but because it was generally believed to prevent the spread of the malady in the flock, the ram being supposed to convey the disease from one animal to another. He had, unfortunately, not been able to make post-mortem examinations so he could not say whether metastasis occurred. As regarded the nature of the tumour there was some difference of opinion. Dr. E. F. Bashford, to whom the specimens were submitted, had no hesitation in saying that the growth was of a granulomatous character, though he did not give any particular reason for this conclusion. On the other hand, Mr. S. G. Shattock, Dr. R. T. Hewlett, and Mr. J. H. Targett thought the growth was an alveolar sarcoma. Dr. de Korté was of opinion that there were two forms of infection, the deeper one consisting of a fibrous network containing comparatively large nucleated cells. There were no blood-vessels in this deeper portion or any ulceration. The superficial portion of the growth was evidently of an ulcerative character and was no doubt the seat of a bacterial infection, which it could hardly escape, exposed as it must be from its situation to all sorts of contamination.

Mr. SHATTOCK and Dr. C. G. SELIGMANN exhibited and described in detail True Hermaphroditism in the Fowl. The ultimate criterion of sex was the structure of the reproductive glands; an abnormal disposition of the sexual passages or misdevelopment of the external generative organs might lead to ambiguity of sex during life, but such observations did not constitute the condition of true hermaphroditism. So far from viewing hermaphroditism as a phenomenon altogether abnormal Mr. Shattock and Dr. Seligmann held it rather to represent a reversion to the primitive ancestral form, for as one descended in the scale it became fairly common as a variation (e.g., in fish) and still lower it became the normal disposition in certain forms. The presence in the human embryo of a double set of sexual passages, male and female, and the undifferentiated state of the sexual glands on their first appearance, pointed to human descent having taken place through a hermaphrodite ancestry. The bird in question was a two year-old Leghorn fowl which externally exhibited the comb and wattles with the spurs of a cock but the tail of a hen. Its sexual physiology was quite negative. The dissection showed a well-developed *left* oviduct and a short diminutive *right;* a vas deferens was present on each side. The sexual glands were convoluted on the surface and of altogether an abnormal form. The left gland consisted of inactive tubuli; serial sections of its lower end revealed two ova unconnected with any tubular structures and provided with a proper follicular wall; the vitellus of each presented an eccentric oval space answering to a germinal vesicle. The serial sections proved the structures in question to be spherical and not cross sections of distended tubes, none of which were anywhere present. The sexual gland of the right side was the smaller and consisted of inactive tubuli like the left, but at one spot a group of tubuli was met with in which active cell proliferation and spermatogenesis were in progress, spermatozoa being present in the more central part of one of the tubuli. The glands were thus, taken together, bisexual; one contained ova, the other spermatozoa, and on the left side (on which ova were present) the oviduct was normal; each gland was furnished with a vas deferens Potentially, therefore, the bird was capable of performing to the full extent both male and female functions. Mr. Shattock and Dr. Seligmann had been led from these and other data to hold that the not uncommon and well-known change of plumage from female to male and more rarely from male to female, possibly indicated a bisexual character not necessarily of the generative glands and ducts but of the glands. They had clear evidence, from having such birds under observation, that where the duck after ceasing to lay assumed the male plumage its sexual proclivities underwent a corresponding change and it would "tread" the female bird. For the production of external male characters the experiments of Mr. Shattock and Dr. Seligmann had shown that the testicular tissue need not be in any way connected with a duct, and, moreover, that a very small piece would suffice to bring about the resul[illegible] I [illegible] lumage Mr Shattock and Dr. [illegible] material to ascertain whether [illegible] ıcing a male internal secretion [illegible] bird, either in the proper sc[illegible]

Mr. T. W. P. LAWRENCE said that tru[illegible] did exist in the human race and about [illegible] had been recorded. The organs from one of these cases were in University College Museum, a testicle on the one side and an ovary on the other. He mentioned another case which had a testicle in the right half of the scrotum and an ovary on the left side. She menstruated from 17 years old till the age of 43 years. She performed the functions of a female till the age of 36 years when she acquired male characteristics, after which she performed the functions of a male.

Mr. HENRY RUNDLE communicated a case (and the preparation and photographs were exhibited) of an Asymmetrical Congenital Malformation of the Lower Extremities. The patient was a male, aged ten years, first seen in 1884, an illegitimate child, well developed in all respects but for the remarkable deformity of the lower limbs. His legs were so short that when he stood erect with the arms dependent the tips of his fingers nearly touched the ground. The weight of the body was supported mainly by the right leg, the length of which was nine and a quarter inches, that of the left leg being 14½ inches. This difference in the length of the limb was partially compensated by the obliquity of the pelvis which was tilted to the right side. The patient died from pulmonary tuberculosis in the Royal Portsmouth Hospital in June, 1904, when the following condition of the limbs was found. In the left extremity the tibia and the fibula were of the full length and presented no marked abnormality except that both were slightly curved forwards and that the head of the tibia was unnaturally flat from before backwards. Articulating with the head of the tibia was an osseous element of triangular shape, three and a half inches long, which represented an ill-developed femur. On the right side the skeleton of the limb was considerably more misshapen and much the shorter of the two. measuring 13 inches as compared with 18 inches on the left. The fibula was five and a half inches long and except for its lower end was uniformly diminutive. The lower end had its normal relations and was of full size; the upper end did not articulate with the other bone of the leg. The shaft of the tibia a short distance from its lower end expanded into a broad triangular process, each of the upper angles of which was enlarged in a manner suggestive of an articular extremity. The outer of these, which was about three inches above the unattached upper end of the fibula, probably represented a greatly flattened head, whilst the inner was possibly an outgrowth of bone into the adductor muscles. The upper border of the triangular expansion was concave and bridged across by a ligamentous structure, with which an undersized patella was connected.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A meeting of this association was held on May 18th at the rooms of the Medical Society of London, Dr. R. Percy Smith, the President, being in the chair.—Prior to the discussion of papers Dr. C. A. Mercier drew the attention of the association to the remarkable state of things existing in the Youghal Asylum, Cork, and proposed the following motion:—

> This association is informed that the auxiliary asylum at Youghal is being carried on under the following conditions The staff consists, in addition to eight nuns, of eight male and five female attendants to 229 male and 149 female patients. For this population of 378 patients there is no resident physician. (In England no more than 50 can be detained in an institution without a resident medical officer.) The superintendent of the Cork District Asylum is held by the Lunacy [illegible] utenant responsible for the administration [illegible] d for the proper treatment of the patients [illegible] regulation of the committee of management he is [illegible] nor to see the patients there [illegible] of management of the Cork [illegible] Inspectors of Lunatics and [illegible] Lieutenant to be illegal. This association expresses its astonishment and profound regret that treatment of the insane so retrograde and so objectionable in character should be possible and trusts that steps will be taken at once by the proper authorities to enforce the law and to terminate so deplorable a mode of treatment of insane persons

The motion was seconded by Dr. G. Bower.—Dr. W. R. Dawson (Dublin) confirmed the particulars stated in the motion and read extracts from reports of Parliament when the subject was discussed there.—The motion was unanimously carried. —Dr. W. M. A. Smith opened a discussion on the Use of Hypnotic Drugs in the Treatment of Insomnia.—Dr. Robert Jones was of opinion that arterio-sclerosis was a very important condition in those cases in which great mental distress prevented sleep and he inclined to the belief that the effect of alcohol, which was used in asylums with a good deal of circumspection, was immediately to dilate the arteries in the cerebral cortex and to help sleep in that way. He had repeatedly used alcohol merely as a hypnotic and one extremely restless patient, who had not been taking his food was fed with a tube and given half a pint of stout twice a day with great benefit He regarded sulphonal as a deadly poison to the neurons and believed that he had seen incurability follow the use of it There was much to be said in favour of chemical restraint and he had found great benefit follow ten grains of calomel He referred to the question of fatigue and to Sir William Gowers's article on the subject He felt certain that he had seen cases in asylum in which the thoughtful administration of a hypnotic in puerperal cases had avoided insanity and in that he had the support of Dr G F Blandford's article in Quain's "Dictionary of Medicine"—Dr Blandford reminded the meeting that the subject was debated before the association not long ago and he had not altered his views since then There was much truth in what Dr H Rayner said on that occasion but *the view was carried too far All recognised the importance* of regulating the digestive organs and giving medicines accordingly but he was certain that he had seen cases in which the giving of narcotic drugs had prevented the patient drifting into insanity and he was in the habit of seeing cases at an earlier stage than those in asylums A restless patient who was suddenly put into a comfortable padded room in an asylum was very likely to go to sleep and he would not dream of giving drugs to such a one He confirmed Dr Jones's remarks about a large dose of calomel and he, too, looked upon sulphonal as exploded Hyoscine was not now mentioned much and appeared to have gone out of fashion It seemed to be a dangerous medicine but he would be glad to hear the *experience* of others on the point —Dr Fletcher Beach thought that much depended on the amount of sulphonal given Doubtless larger doses of it were given in asylums than for the treatment of nerve cases He had never administered more than 15 grains at the bedside and its use in cases verging upon insanity had been very beneficial —Dr Mercier was not sure that there had not been a wave of therapeutic Nihilism in the specialty Patients were sent to asylums in order to be detained under care and treatment, yet as soon as they arrived there the cry was that they must not be restrained If they were to be treated by the open door why should not that be done outside? He saw no objection to chemical *restraint* and *related cases* in which sudden breakdown had been treated with narcotics and been followed by immediate cure He also laid great stress upon a full stomach as a powerful aid to sleep —Dr Bedford Pierce defended sulphonal as he had found it a good friend, though he agreed that hypnotics should be very sparingly used —Dr W C S Clapham deprecated giving calomel to patients who had suffered from typhoid fever, and Dr E Kingdon said a good word for hyoscine $\frac{1}{75}$th of a grain *hypodermically —Dr F D* Savill advocated the taking of the arterial tension before administering hypnotics as most of them affected the arteries in some way —Dr Harry Corner believed that 90 per cent of the cases could be treated without hypnotics by mechanical and food aids, though much depended on the nurse He rarely gave hypnotics without regretting it —The President said that he had not seen any disagreeable after effects from hypnotics but he had known people complain of extreme weariness and exhaustion after veronal Dr Jones had referred to sulphonal as a deadly poison to the neurons but all the drugs which had been mentioned were deadly poisons to something He thought sulphonal should not be relegated entirely to the scrap *heap To some practitioners chloral and* morphine seemed about the only drugs of that class known —Dr Smith replied —Mr G T Hine, F R I B A (an honorary member of the association), exhibited and described the plans of the new London County Council asylum projected at Long Grove, near Epsom —In the evening the members dined together at the Café Monico ——A meeting of the Northern and Midland division of this society was held at the Retreat, York, on May 4th, Dr T W Macdowall *of Morpeth being* in the chair —*Dr H J* Mackenzie of York described a case of Neurasthenia followed by Melancholia The patient was a man aged 53 years who had suffered from indigestion for years and from neurasthenia for about five months Treatment and dieting had not benefited his indigestion and he had been steadily losing flesh One sister had been insane On admission to the Retreat he was very thin, weighing just under eight stones though a tall man He was much depressed and had a settled belief *that he could never be better* and that his stomach was dead and that it was useless to eat The sight or even the mention of food would bring on an attack of hysterical screaming He had soon to be fed forcibly for a few days and then he took food again himself, but he did not gain weight and his mental state grew worse He developed a hæmatoma auris which suppurated and had to be opened freely, but in the end it healed well and with little deformity At last he refused food entirely and had to be fed forcibly four times a day for about four months Under this treatment he improved physically, but it was not till he had gained about 20 pounds in weight that any marked mental improvement set in He improved steadily from this time and went home well after seven and a half months' residence He has remained well since

Dr [illegible]
in a [illegible]
and [illegible]
with [illegible]
exhibited all the symptoms of acute mania, were coincident with a menstrual period and each was succeeded by a lucid interval of six weeks The number of white blood corpuscles per cubic millimetre of blood was 16,000 at the beginning of the attack, rose to 24 000 at the height of the attack, and on recovery fell to 9000 The case was complicated with malignant disease, for which both breasts were removed in 1902 There has been a recurrence of this, which is being treated with x rays —Dr Thomas Johnstone of Leeds read a paper on Dementia Præcox He thought that the best translation of dementia præcox was *premature dementia, though it was usually* translated as adolescent insanity The mental symptoms varied according to the age at onset and the previous education and mental abilities In the present state of knowledge it was not always possible to tell whether a patient with adolescent insanity or dementia præcox would become rapidly worse or would make an apparent recovery Many cases of dementia præcox which apparently recovered relapsed late in life and showed symptoms of katatonic excitement or stupor or these conditions alternating and were called by some resistive melancholia The prognosis was very grave —Dr William Francis Menzies of Cheddleton Asylum, Leek, read a paper on Some Points connected with Tuberculosis in *Asylums* He explained that the *asylum death rate from* tuberculosis was not falling in ratio to that of the general population and claimed that a considerable percentage of cases of higher grade amentia and primary adult insanity were precipitated by the tuberculous infection These early cases were the source of most asylum tubercle and acted as foci from which others became infected In conclusion, he discussed the diagnosis and treatment of the disease —Dr Bedford Pierce gave details of two cases of Atonic Dilatation of the Stomach *successfully treated by* Stendall's method which principally consists in the continuous application of heat to the abdomen Abundant ordinary food is given at regular intervals Drugs are not administered A rapid gain in weight with contraction of the stomach was followed by recovery

EPIDEMIOLOGICAL SOCIETY.—At a meeting held on May 19th Dr B A Whitelegge, the President, being in the chair, Dr Arthur Ransome read a paper on the Significance of Phthisis Death rates, illustrated by charts showing those for England and Wales since 1838, for Scotland since 1871 for Ireland since 1861, and for shorter *periods in Liverpool* and Manchester the deaths *of males* and females being shown separately Until 1874 certification of the cause of death was not compulsory, but notwithstanding much admitted irregularity he believed that the returns as regards phthisis were approximately correct Phthisis was communicable but these curves showed that it was also endemic carrying off like percentages in successive years in each locality It also had a tendency to periodic waves something like the epidemics of the exanthemata at *intervals of about a dozen years*, and while *on the* whole falling in England and Scotland but rising in Ireland, the undulations in the curves for the two sexes corresponded in the great majority of instances He had been quite unable, even in the case of a single community as that of Liverpool, to trace any connexion between the mortality and the "weather" temperature or rainfall In England the mortality had fallen since 1838 from 3800 to 1100 per 1,000,000, or over 0 70 per cent In 1894, judging from the previous rate *of decline, he had predicted the practical* extinction in another 30 years, but these hopes were not likely to be fulfilled, the rate of decline having suffered to get all the water removed from the ends of the fingers and so they did not fit closely. The gloves should be cleansed, some powdered talc should be dusted into them, and then they should be sterilised in a steam steriliser. When taken out they were quite dry and slipped on easily. The talc also prevented accumulation of secretion in the fingers, so that if the glove should be accidentally pricked no fluid escaped. Of course, the hands were as carefully sterilised before putting on the gloves as if no gloves were used. In putting on the gloves the fingers should not be stroked with the naked hand, but a piece of sterilised gauze used for the purpose. As regards expense, a pair of gloves would last for several months. Mr. Campbell mentioned as other sources of contamination hairs and scales from the surgeon's and his assistants' heads and particles ejected from the mouth in speaking. Contamination in this way could be almost entirely avoided by taking care that the heads did not come in contact and that silence was preserved.—Dr. A. G. Robb then read a paper on Small-pox in Belfast, in which he gave a very full account of the recent epidemic in that city. Altogether there were 178 cases and nine deaths, giving a total death-rate of 5·05 per cent.

Harveian Society of London.—A meeting of this society was held on May 11th, Mr. C. B. Lockwood, the President, being in the chair.—Dr. Hugh Walsham read a paper on the Use of Roentgen Rays in the Diagnosis of Diseases of the Chest, illustrating his remarks by 63 lantern pictures. He first pointed out that the airless and unexpanded lung was as opaque to the x rays as were the other soft tissues of the body. He then proceeded to discuss the methods of examining the chest with the rays and gave a short description of the retro-sternal and retro-cardiac triangles seen by this method. He next passed on to the shadows of the normal chest and showed how the heart differed in its position with relation to age. Aortic aneurysm, fluid in the pleura, pneumothorax, and pyopneumothorax were then successively considered. The diagnosis of pulmonary tuberculosis, both early and advanced, by the x rays was illustrated by slides of this condition. Cavitation was then alluded to, Dr. Walsham maintaining that a small cavity could be detected by the x rays that would be missed by the ordinary methods of examination. Pulmonary emphysema and fibroid phthisis were also shortly discussed.—Dr. C. Theodore Williams referred to the difficulty of determining between aneurysm and new growth. and to the question of detecting early pulmonary tuberculosis.—Dr. E. Clifford Beale said that the movements of the diaphragm as seen with the screen were very important to note. The diaphragm as a rule appeared to move equally without any change of shape but in certain morbid conditions of one side the excursions of the diaphragm on that side were often found to be less than on the healthy side. He had never succeeded in seeing the action of the diaphragm in cases of hiccough. The aortic bulging seen by the screen was always noted to be freely pulsating and might not of necessity be a morbid condition at all. In a suspected case of early tuberculous disease of the lung he had seen by the screen that the bony framework of the chest was exceedingly narrow, although the patient had broad and well-developed shoulders, and in several of the slides shown that evening he had been struck by the manner in which the contraction of the upper part of the chest in tuberculous patients was demonstrated in cases where external appearances indicated no such contraction.—Dr. D. B. Lees asked whether radiographers claimed to be able to demonstrate the presence of disease at the apex of one lung in a very early stage. So far as he had seen radiography was unable to prove incipient apical tuberculosis until its presence was clearly demonstrable by careful light percussion. He concluded by referring to the case of an infant ten months old in which the diagnosis of the existence of a diaphragmatic hernia was confirmed by an x-ray examination.—Mr. R. Higham Cooper agreed that limitation of diaphragmatic movement was the earliest radioscopic sign in tuberculosis and had found this in several cases in which the physician had failed to make a diagnosis by ordinary methods; at the same time it sometimes happened that there was no x ray evidence to be found even when diagnosis was fairly clear by percussion and auscultation. It had once happened that a girl about 15 years of age whom he was examining with the fluorescent screen had an attack of hiccough. His attention was called to the hiccoughs by observing a curious sudden flattening of the dome of the diaphragm on the left side which he found occurred with each hiccough. It was curious that there was no alteration on the right side. There was no visceral disease, the girl being under examination for supposed foreign body. He had never observed radioscopically another case of hiccough.—Dr. H. W. G. Mackenzie said that he had at present a patient in St. Thomas's Hospital suffering from a large aneurysm of the arch of the aorta in whom in 1898—i.e., seven years ago—the diagnosis of aneurysm had been made by means of the x rays. He formerly thought that the diagnosis of aneurysm was too frequently and too readily made on screen examination but subsequent history had so often confirmed the correctness of the diagnosis that he now believed the x rays to be of great value in doubtful cases. Where the ordinary physical organs did not give evidence of tubercle his experience had been that the x rays failed to do so also.

Society for the Study of Disease in Children.—A meeting of this society was held on May 5th, Dr. George Carpenter being in the chair.—Mr. Sydney Stephenson showed a girl, aged four years, with Silver Deposit on the Cornea due to the application of solid nitrate of silver to an ulcer.—Dr. F. J. Poynton showed five children illustrating Combined Aortic and Mitral Disease. In one with a double mitral murmur a previously well-marked aortic diastolic murmur had completely disappeared. In another the aortic murmur had almost disappeared.—Dr. Theodore Fisher (Bristol) said that in his opinion harsh murmurs ascribed to aortic disease were sometimes due to other causes.—Mr. George Pernet showed a boy, aged eight years, with Generalised Alopecia.—Mr. Ernest Clarke said that he knew of a case in which high-frequency currents had proved beneficial.—Mr. Clarke showed a child with Bilateral Coloboma of the Iris, in the down and out instead of the usual directly downward position. There was no notch in the lens or the lids. Nystagmus was present, probably due to a very thin choroid and great refractive defect. He attributed the condition to intra-uterine inflammation rather than to arrested development in the closure of the fissure.—Dr. Edmund Cautley showed a child, aged 12 months, with Bilateral Periostitis of the Femur. The child had been brought up on a diet conducive to scurvy. She came under notice at ten months of age for swelling of the right knee and thigh of one month's duration and a similar condition of the left side for two weeks. She was anæmic, rachitic, wasted, feverish, and had two teeth but no discolouration of the gums. There were much swelling, pain, and tenderness. The right side diminished but at first the left leg became worse. An exploratory incision above the knee yielded no pus. The temperature subsided in a few days and recovery was steady and uneventful; the child gained 26 ounces in weight in four weeks. There was still considerable thickening of the lower half of each femur. He regarded the case as syphilitic on account of the symmetry, the course, the result of the exploratory incision, and the absence of signs of scurvy. There was almost certainly some epiphysitis as well. The mother had had one miscarriage.—Dr. F. Parkes Weber showed a girl, aged 11 years, with Wasting of the Left Leg and Right Hand and Forearm, beginning insidiously a year ago. Sensation and electrical response were deficient in the affected parts and there was reaction of degeneration in the muscles of the thenar eminence. He regarded the condition as a dystrophy of the peroneal type. There was no family history of the disease.—Dr. Cautley agreed that it was a form of peroneal atrophy and drew attention to the "claw-like" condition of the hand, the wasting of the vastus internus, and the presence of pes cavus. He had shown a case before the society three years ago which had begun at the exceptionally early age of 18 months. As in the case of Dr. Weber's patient there was no family history but the child had had measles. He thought that the sporadic cases were perhaps different in their pathology from the hereditary ones and often secondary to specific fevers.—Dr. Carpenter showed cases of Congenital Deformity of the Hands in several members of the same family, chiefly absence of the nails and the terminal phalanges of the little fingers. Two children, their mother, an aunt, an uncle, and some of his children were affected. The mother's father had two thumbs on each hand and his brother had webbed fingers.—Dr. Carpenter and Mr. J. P. Lockhart Mummery showed a specimen of Congenital

Hypertrophic Stenosis of the Pylorus treated by pyloroplasty The patient, who was an infant, aged three months, died on the morning following the operation —Dr L W Marshall (Nottingham) showed a specimen of Multiple Papillomata of the Larynx *from a boy, aged four years* —Dr J Porter Parkinson showed a girl aged seven years with Multiple Gummata and a baby four months old with Bilateral Birth Palsy of the Arms —Mr Hunter F [illegible]od showed a case of Primary Tuberculous Disease of the Middle Ear with secondary involvement of the cervical glands

EDINBURGH OBSTETRICAL SOCIETY —A meeting of this society was held on May 17th Dr N T Brewis the President occupying the chair —Sir J Halliday Croom read a paper on Some Curiosities of Curetting After discussing in detail some of the many theories of the primary etiology of cancer Sir Halliday Croom laid special emphasis on the extreme value of early diagnosis in malignant cases The only comparatively certain aid to this early diagnosis of cancer was got from the microscopic examination of the débris removed by the curette A soft friable enlargement *or growth of the cervix bleeding readily on examination* was not sufficient to diagnose cancer He knew of such cases which were now quite well years after the examination In sending specimens to a microscopist a sufficient amount should always be forwarded and always be accompanied with a short account of the clinical facts Even in cases where this rule had been observed errors might arise, as Sir Halliday *Croom* illustrated by some cases in [illegible] y seemed to refute the [illegible]opist Though such cases [illegible]ent to confirm still more [illegible]asing all diagnosis on the [illegible] *microscopically As to the* accidents which might follow curetting, Sir Halliday Croom cited a case in which stenosis of the os and retention of the menses for two periods simulating *pregnancy, had occurred in* a young married woman whom he had curetted after an incomplete abortion An illustration of perforation of the fundus by the curette was given in the history of a case where in *curetting after an abortion the practitioner had perforated* the fundus When seen in consultation there was a loop of intestine prolapsed in the vagina Though such cases are rare in this country many cases have been recorded, as Harvey s case quoted by Kelly in which six feet of intestine was cut off In Hessert s case the bowel was injured during curettage to such an extent that *resection of four feet was performed with a fatal result* The safest instrument was the finger for removing tissue after an abortion or labour Two cases were related showing the disappointments of curettage in which Sir Halliday Croom had operated for endometritis in the hope of rendering pregnancy more probable but *in each case* the results were opposite to those desired as the patients never *menstruated again and atrophic changes supervened* —Dr James Ritchie, Dr F W N Haultain Dr J W Ballantyne, Dr H M Church, Dr J Haig Ferguson Dr M Dewar, Dr W Fordyce, Dr J Lamond Lackie and the President made remarks on the paper, and Sir Halliday Croom replied

PATHOLOGICAL SOCIETY OF MANCHESTER —A [illegible] held on May 10th Dr A Donald [illegible]e chair —Sir William J Sinclair [illegible] the Association of Flexion of the *Uterus with Erosion and Cancer* —The President showed a Macerated Fœtus which had been retained in the abdomen for nearly four years The case was diagnosed as one of extra[illegible]œtus in Septe[illegible]hat time [illegible] The first of the [illegible]on went on to term and the child was born alive The first four months of the next pregnancy were uneventful, then she began to have severe abdominal pain and the temperature and pulse ran up Abdominal section was performed and the macerated fœtus was removed The patient made a good recovery but miscarried on the tenth day The macerated fœtus lay in a sac which on dissection was found to be one horn of a bicornate uterus The sac was inflamed and adherent to bowel and omentum at one point —Mr W P Montgomery showed an Embryoma removed *from the rectum* —Mr C Roberts showed and described a Retroperitoneal Multilocular Cyst Adenoma —Other preparations were exhibited as Card Specimens

Reviews and Notices of Books.

A Modern Utopia By H G WELLS In one volume London Chapman and Hall, Limited 1905 Price *7s 6d*

Mr Wells has written a fascinating book It is clever almost uncannily clever so beautifully written that the learning of the many and valuable lessons which the author has to teach becomes a veritable pleasure, and so suggestive that the reviewer has difficulty in keeping what he has to say strictly to the book, the temptation to digress upon a dozen contentious themes being of the strongest Mr Wells s A Modern Utopia differs from previous attempts to formulate an ideal world scheme by being kinetic and not static, to borrow his own phrase Previous Utopias have all imagined a finite and perfect condition of things which being reached no one would or could desire to improve upon All abuses *in these imaginary realms* are done away with legislation becomes unnecessary because there is neither crime nor incentive to crime kings are unnecessary because complete *order* prevails *among the people*, and wars are unnecessary because there are no national grievances Previous Utopias have, in short, amounted to the description of a sort of splendid and stagnant anarchy *in which laws* physical and moral are suspended, there being no further use for them Mr Wells s Utopia is alive his world state has developed out of existent conditions that we can all observe (the majority of us do not observe them at all because the majority of us are shamefully dull) and it should continue to develop on the lines laid down into something better No limit can be set to the possible improvements of a Utopia of the kinetic sort because as man puts behind him more and more solid knowledge his possible grip of what lies before him becomes more and more comprehensive *The acquisition of learning* by the world implies a fitness to acquire more learning and Mr Wells s *fantasy founded* on this truism, gains its marked realism thereby

In previous Utopias no notice has ever been taken of the possibilities *for development of the* human race that are offered by the increased use of mechanical contrivances and it is because Mr Wells does not admit of any limit *to the advantages that we may derive from* future discovery in natural science—using the words natural science in their most comprehensive sense—*that he has been able to write so extremely hopeful* a book For Mr Wells s belief in the possibilities of our world—or another world physically similar to ours, inhabited by persons of like *frailties and capacities to ourselves*—is gloriously hopeful Previous Utopias have always considered man as a rather degenerate animal, more or less anchored to the place where he was *born* and *condemned* to protect himself by his own puny muscular effort against the troubles of his environment For such people the simplest *method of framing a scheme for* ideal happiness would be to remove the chances of physical ill both from within and from without—Utopians should be a *chosen people protected elaborately from* all stress and misery The Utopia was consequently a carefully selected spot, a fertile and unknown valley or a settlement surrounded by an impregnable *rampart* Here wild beasts noxious insects, storms and tempests were unknown and into this place non Utopian persons could not penetrate Within such a city *of refuge by the operation of a* conjoint determination not to be criminal or dirty, ideal happiness should reign This was all very well when for example ten *miles an hour* was *considered* quick *travelling* and artillery had not made walls appear ridiculous *for defensive purposes*, but nowadays such a secluded retreat cannot be made to appear real or reasonable. All the world is nowadays open to all the world—with considerable difficulties, it is true, to be overcome. These difficulties in real life are being gradually removed, while Mr. Wells in his romance has simply and completely removed them. His Utopia is a planet similar to the earth in every respect upon which a population, which started similar in every respect to our own, has undergone development along sane and orderly lines, has placed a premium upon scientific and imaginative work, and has consequently succeeded to an empire over physical and natural potentialities which we on earth are without.

Throughout the book Mr. Wells makes the sanguine and, as we like to think it, sound assumption that man is a good fellow of generous instincts, capable of better things, and sorely hampered and overladen by the foolishness of bygone times. He imagines a condition of things when a train, itself a sort of moving city, would run round a world of our size in about ten days at an average speed of something over 200 miles an hour, tunnels, of course, being constructed in many places under the sea. Naturally, the necessity for little states and, comparatively speaking, little empires disappears. The whole population of the world is fluid instead of being so many sticky lumps adherent to certain localities. The inhabitants of Mr. Wells's world-state all talk the same language, there are no tariffs, no rivalries, no obstructions whatever to intercommunication; labour flows from the region where it is not wanted to the region where it is wanted, the State stands behind the worker to provide him with secure employment, and the splendid economy which results from a fusion of interests working according to design is achieved. All this the author pictures in such convincing language that we are almost compelled to ask why we cannot at once drop the existing condition of things and run our world on Mr. Wells's plan. It is of course his art that makes this proceeding appear really possible, for he points out carefully that the position in "A Modern Utopia" has only been achieved after generations of intelligent evolution. But his optimism has been able to believe that man, if he gave proper play to his instincts and impulses, would abolish by common consent many of the disorderly and vexatious conditions of life that find their ultimate expression in wars by land and sea, in deaths from starvation or hideous preventable disease, in divorce court revelations,—and so on. How this reformation of our sinful and ataxic old planet might be brought about and what the results would be to different classes of the population make up the bulk of the book.

How would such a world be ruled? Mr. Wells would have it ruled by a class which, out of compliment to the Japanese, he names the Samurai, who shall be the "voluntary nobility" of the world-state, their election being due simply to their own self-mastery and ability. The Samurai are a class who deny themselves certain luxuries and who show themselves to possess certain intellectual equipment. They are neither ascetics nor fanatics; they exhibit their powers of self-control by abstinence from sensual and frivolous pleasure, but there is none of the foolish abjurations which in the world's history have often made "holy man" and "silly ass" interchangeable terms. In return for their reasonable self-denial and their fixed resolve to attain to higher things and to look on the nobler side of life the temporal power of Utopia is vested in them. The children of such persons, being educated in the same atmosphere, would naturally tend to belong to the Samurai class, but there is nothing hereditary about the caste, Mr. Wells holding, in refreshing contradistinction both to reckless evolutionists and convinced reactionaries, that the operations of heredity are of too uncertain and complicated a kind to be depended upon for the breeding of a ruling class. Medical men are placed by Mr. Wells among the Samurai as a tribute to the nature of their work. Their functions are, of course, in his imaginary world-state, largely preventive. The abolition of poverty and haunting anxiety has removed enormous classes of diseases or complications of disease. General and sensible education has aided in simplifying pathology. A common language and free intercourse between all parts of the world have enabled epidemiology to stamp out the scourges that now decimate many peoples; and the medical man remains as the guardian of the health of the world-state, as adviser of the sanitary measures to be taken in the future developments of an immense community that is resolved never to be standing still, and as the wise and reasonable friend of a wise and reasonable folk.

We cordially recommend "A Modern Utopia" to all our readers. It is not quite an easy book to follow for several reasons, among which must be counted the absence of didacticism. This makes it necessary for the reader to do some of the thinking instead of contenting himself with assenting to or dissenting from cock-sure statements. Well, the book is thoroughly worth thinking about.

The Treatment of Diseases of the Eye. By Dr. VICTOR HANKE, First Assistant in the University Eye Clinic of Hofrath Professor E. Fuchs in Vienna. Translated by J. HERBERT PARSONS, B.S. Lond., F.R.C.S. Eng., and GEORGE COATS, M.D. Glasg., F.R.C.S. Eng. London: Hodder and Stoughton. 1905. Pp. 222. Price 3*s.* 6*d.* net.

WE are somewhat at a loss to understand why Mr. Parsons and Dr. Coats have translated this work. Not that we mean to disparage it, as the author might reasonably consider that it would be useful to those attending his demonstrations and would be a guide and a help to those who were students in Professor Fuchs's wards. It is a very fair *résumé* of the means of diagnosis and treatment ordinarily pursued in an ophthalmic hospital, putting aside operative proceedings and taking for granted that the student is familiar with optics, subjects that usually occupy considerable space in works of this kind. But when this has been said we fail to see that it offers any marked features of superiority to such treatises as those of Swanzy, Nettleship, and Jessop in England and several that have been published in America. The reader will find the names of a considerable number of new remedies, such as airol, dionin, largin, sodium sozoiodol, argentamin, ichthargan, xeroform, iodopin, europhen, gallicin, itrol, hetol, and others, but they are not very warmly recommended. Experience is required to recognise in what particular form of disease each may be useful and in the meantime delay may be occasioned by their procurement and application, thus neutralising any advantage they may possess over such well-approved remedies as alum, silver nitrate, and cocaine. In like manner the suggestions for establishing the diagnosis of certain forms of disease are not always given in such a way as to create much confidence; let us take, for example, diphtheria of the conjunctiva. The author states that the diagnosis of this condition is necessary but extremely difficult "since only a complete bacteriological examination with smears, cultures, and animal inoculations gives a conclusive result." The discovery of diphtheria antitoxic serum facilitated the differential diagnosis, though it is added "only true diphtheritic inflammations, though not all such, are cured speedily and with certainty." The parenthetic remark "though not all such" seems to introduce an element of uncertainty which is not very satisfactory either to the surgeon or to the patient. We are told that as soon as a membranous or a diphtheritic inflammation is perceived a bacteriological examination should be undertaken, an exact clinical history should be ascertained, and examination should be made of the genitals, the nose, the mouth, and the throat; but here again doubts, after taking all this trouble, obtrude themselves, for it is said in the very next sentence that "the presence of rods like the diphtheria bacillus is not diagnostic, since the xerosis or pseudo-diphtheria bacillus behaves similarly both to stains and in cultures and can only be distinguished by its virulence in animals." It seems that this proceeding might be resorted to in the first instance with advantage in the matter of time. In a final sentence the author states not very clearly that "the absence of bacilli, however, and the presence of cocci—pneumo-, gono-, staphylo-cocci—decide the diagnosis and the treatment to be chosen." For injections may be employed the three strengths of Behring's serum, the Vienna serum, or Merck's serum, containing from 600 to 1000 units in two cubic centimetres, either of which may be injected into the skin of the eyelid even of a child without danger. The injections are to be repeated daily in the same quantity and strength as long as membranes and infiltrates are still visible. It is noticeable that corneal complications are not influenced to any great extent by the serum therapy but must be treated according to the ordinary rules—namely, warm compresses of atropin. No reference is made to chlorine water which was at one time strongly recommended in diphtheritic affections of the eye. The cleansing of the conjunctival sac is ordered to be effected by a solution of 1 in 5000 of potassium permanganate, Kalt's irrigation with 1 in 4000 hydrargyri perchloride or chinosol, 2 to 10 per cent. protargol, and 10 per cent. itrol. Protective dressing should be applied to the sound eye if only one be affected. The work, as a whole, is sensibly written and is well up to date.

Atlas of Human Anatomy. By WERNER SPALTEHOLZ, Extraordinary Professor of Anatomy in the University and Custodian of the Anatomical Museum at Leipsic. Edited and translated from the Third German Edition by LEWELLYS F. BARKER, M.B. Toronto, Professor of Anatomy, University of Chicago. With a Preface by FRANKLIN P. MALL, Professor of Anatomy in the Johns Hopkins University, Baltimore. In three vols. With 935 illustrations, mostly in colours. London and Philadelphia: J. B. Lippincott Company. Small quarto, pp. 872. Cloth, £2 2*s*. net per set.

THERE is no doubt that an atlas such as this is a considerable assistance to the student of anatomy if it is used with proper discretion, but the ever present danger, which is fully recognised by all teachers of the subject, is that the presence of these pictorial aids breeds a neglect of dissection and dissecting-room study. We confess that we experience a feeling of regret when we see anatomical atlases in the hands of students in their earlier years, knowing by experience what to expect. To the more advanced student and those who have quitted the dissecting room these remarks are not intended to apply. Anatomy is a subject which, if the knowledge is to persist and to lead to practical results in the advance of medicine and surgery, must be learned directly from the body, and no models or atlases, however excellent they may be, can replace actual dissection.

As a work of art the atlas of Professor Spalteholz is deserving of very great praise and the amount of labour entailed in its production can be gauged when we learn that eight years of necessity elapsed between the issue of the first and the third or final section of the book. Practically all the drawings are from original preparations but at the same time are, so to speak, composite, the mean arrangement of structures being depicted. In all cases the right side of the body has been selected for illustration. We understand that most of the dissections were prepared by Professor Spalteholz himself. The original drawings are mainly from the hand of a well-known anatomical artist—Bruno Héroux.

The first volume, which is somewhat slender and consists of 236 pages, is entirely devoted to illustrations of the bones, the joints, and the ligaments. The illustrations of these structures do not appreciably differ from those with which English students are familiar and really convey an excellent idea of the actual structure. The plan of depicting the smaller bones of the skull surrounded by outline drawings of bones with which they articulate is excellent. Muscular attachments are marked in red outlines after the style made familiar to us by Holden and probably originated by Mr. Cornelius Hanbury. It is most unfortunate that in printing the muscular attachments on the fibula the "register" is displaced; this will inevitably lead to great confusion. Several plates to illustrate the arrangement of the cancellous tissue in the various bones have been introduced at the end of this volume.

The second volume, consisting of 239 pages, deals with regions, muscles, fasciæ, heart, and blood-vessels. Illustrations from all points of view have been introduced. The author apologises for the somewhat rigid appearance of the muscles which have been drawn from formalin specimens. The colour used for these structures is certainly an improvement on that in some atlases with which we are acquainted, but, nevertheless, it is still unnatural. The bursal sheaths of the different tendons of the hand and the foot are well brought out but the tendinous attachments of some of the spinal muscles are very indistinct. The heart and the blood-vessels are well represented but we notice discrepancies in the mode in which the origin of the subclavian trunk from the innominate stem is depicted in the different figures. It is a pity, too, that the various sacral nerve trunks are not named in the plate depicting the arteries of the pelvis. The author has, from pressure of time, been compelled to omit all illustrations of the lymphatics, which we consider a great defect.

The third volume is about equal in size to the other two combined. This important section illustrates the viscera, the brain, the nerves, and the sense organs. We do not consider the illustrations and the descriptions of the viscera superior, or, indeed, equal, to those which have recently emanated from English anatomists. The section on the nervous system is the best part of the whole atlas. The author has been fortunate in obtaining the assistance of Professor Flechsig Professor His, and Professor Eisler, from whose preparations some of the drawings have been made, whilst others are from specimens of Dr. Held. Colour printing has been resorted to freely to distinguish various tracts. We have found it difficult to distinguish some of the tints used when reading by artificial light although they are easily recognised by daylight.

Professor Barker of the University of Chicago is responsible for the English translation and has performed his task in a most satisfactory manner.

LIBRARY TABLE.

Essentials of Nervous Diseases and Insanity. By JOHN C. SHAW, M.D. Fourth edition, revised by SMITH ELY JELLIFFE, M.D., Ph.D. Illustrated. London: H. Kimpton. 1904. Pp. 196. Price 4*s*. net.—This little work is intended as an introduction to larger books and has evidently supplied a demand, at any rate in the United States, since the present is the fourth edition. In works of this kind the aim must be to compress into a limited space the essentials of what is usually an extensive subject and the results achieved often leave much to be desired. In the present instance it is expected that the student should read in conjunction with this volume Edinger's lectures on the Structure of the Central Nervous System and a monograph by W. Browning on the Vessels of the Brain in order to gain anatomical and physiological information which the limits of the present work made it impossible to include. The contents of the book are divided into seven sections, dealing respectively with the neuroses (functional disorders), with diseases of the peripheral nervous system, of the spinal cord and medulla, of the cerebral and spinal meninges, of the brain, with certain trophic diseases, and with mental diseases. The chapters under these sections cover the diseases of the nervous system and mind which are commonly met with. Summary descriptions of the essential features of these are of course all that can be expected and they are given, as far as possible, under the headings of etiology, pathology, pathological anatomy, symptoms, diagnosis, prognosis, and treatment. References are given to writings on the subject-matter of the more important chapters at the close of these and at the end of the work is a list of the chief periodicals which are devoted to the study of nervous and mental diseases in different languages. We observe that the subject of aphasia is treated under five headings, one of which is "true or intellectual aphasia," which does not appear to be a condition capable of separation from "motor," "sensory," or "associative" aphasia, as is here attempted. Amongst the insanities is a state described as "hysterical insanity," which is not, we believe, usually regarded as an entity and could not, we think, be distinguished as such from the description given. It is well known, of course, that hysterical symptoms are exhibited in some cases of mania. The description of the insanities due to alcohol leaves something to be desired. Adverse criticisms might in like manner be here and there advanced but on the whole the information which the book affords is as full as its purpose requires and it is also correct. The value of the work would be enhanced without appreciable addition to its size by including a chapter on methods of clinical examination in diseases of the nervous system. The text is elucidated by numerous illustrations.

Surface Anatomy. By T. GILLMAN MOORHEAD, M.D. Dub., M.R.C.P. Irel., Physician to the Royal City of Dublin Hospital; late Chief Demonstrator of Anatomy and Joint Lecturer in Applied Anatomy, Trinity College, Dublin. London: Baillière, Tindall, and Cox. 1905. Crown 8vo, pp. 150. Price 4*s.* 6*d.* net.—Quite a number of manuals of surface anatomy have been published during the last 12 months. Several of these have already been noticed in our columns. The volume now before us differs in no appreciable degree from its predecessors and possesses no feature of novelty. The book is arranged on the usual lines and the information given is accurate and fairly concise. Photographs from the model are reproduced to illustrate the surface markings of the body and several coloured outline diagrams show the relations of the thoracic and abdominal viscera to superficial bony points. We think that these diagrams might be considerably improved upon with advantage. With two remarks made by the author in his preface we cordially agree: the first is to the effect that the best model the student can employ is himself, and the second is that a knowledge of deep anatomy is essential before the facts of surface anatomy can be appreciated. We may further add that until the practical bearings of the facts given in books on surface anatomy are also appreciated the books form very dull reading.

Chemistry in Daily Life. By Dr. LASSAR-COHN. Translated by M. M. PATTISON MUIR, M.A. Third edition. London: H. Gravel and Co. 1905. Pp. 340. Price 5*s.*—We are glad to find that this little book is so widely appreciated, as is evident from the fact that a third edition, revised and augmented, has been called for. It is charmingly written and deals with those chemical phenomena which, as the translator says, are intimately bound up with our daily lives and after all it would be difficult to find many chemical phenomena which are not intimately bound up with our lives. Popular ideas as to what chemistry is are somewhat vague, the word chemical being often employed in a contemptuous sense, meaning disagreeable or poisonous substances, and the man dealing with them is often looked upon as a mysterious, if not an offensive, person. Yet after all water, air, chalk, ink, soda-water, alum, glass, and other familiar things are chemicals. Considering the size of the volume it is wonderful how the author has been able to include so many topics. He has done it with skill and the translator has rendered the story in simple and attractive terms. It is the sort of book that should be in the hands of every schoolboy and it would be saying little for his intellectual capacity if he failed to read the chapters with profit and pleasure.

The Food Inspector's Handbook. By FRANCIS VACHER, F.R.C.S. Edin., Medical Officer of Health of Cheshire. Fourth edition. Illustrated. London: The Sanitary Publishing Company. 1905. Pp. 231. Price 3*s.* 6*d.*—This little book is primarily intended as a guide for the use of food inspectors and that it has served its purpose satisfactorily is indicated by the fact that three editions have been issued since the publication of the first edition in 1892. It contains in a collective form the kind of information which is necessarily scattered otherwise over a number of works on special subjects. Thus besides the adulteration of food there are chapters on animals, carcasses, butchers' meat, poultry, game, fish, fruit, and vegetables, with a description of the appearance and the character of foods which warrant their condemnation as unfit for consumption or their approval as the case may be. Illustrations are given which are calculated to be helpful in the task of diagnosis. The chapters will be appreciated by all those occupying the important office of food inspector.

The Medical Annual: A Year-book of Treatment and Practitioner's Index. 1905. Twenty-third year. Bristol: John Wright and Co. Pp. 843. Price 7*s.* 6*d.* net. Stereoscopes 2*s.* or 2*s.* 6*d.* extra.—In this the twenty-third year of the "Medical Annual" it has been found necessary to bow to the inevitable and to adopt a larger page in order that height and width should be more proportionate. This volume therefore commences a new series which will differ only from its predecessors in requiring more room on the bookshelf. The change has been rendered necessary by the advance made in medical science. On the subjects of tropical diseases alone quite a number of affections are described which receive no mention in the latest text-books. The editor tells us that every paragraph "may be taken as something which has been left, after a repeated process of pruning," and every article is signed by a responsible editor capable of forming a valuable opinion upon the facts recorded. A selection of stereograms illustrating some diseases of the eye are included in the volume. These plates are reproduced from the stereograms in Neisser's "Stereoskopischer Medizinischer Atlas," edited by Dr. W. Uhthoff of Breslau. The letterpress accompanying them is a free and abridged translation of the German text by Dr. A. Hugh Thompson. For readers who have no suitable stereoscope the publishers provide a simple but effective instrument; directions for its use are given. The new volume is a worthy member of its series and is produced on the lines which have made the Annual so successful in the past. It is primarily intended as a work for rapid reference. We notice that in the official directory the name of Sir Henry F. Norbury is still given as that of the Director General of the Royal Navy Medical Department. The book is illustrated with 30 plates and many diagrams. There is a good general index.

JOURNALS AND MAGAZINES.

Archives of the Röntgen Ray.—In the issue for April is an interesting contribution by Mr. Robert Jones and Dr. David Morgan on Osseous Formations in Muscles due to Injury. The subject is treated very completely and the salient points, including radiographic appearances of 17 cases, are set forth in tabular form, and radiographs of several of the more interesting cases are reproduced. The article on the Treatment of Epilepsy by the X Rays, by Dr. Horace Manders, is also worthy of perusal. Full notes are given of a rather severe case treated by him and the result up to the time of writing had been most satisfactory. Dr. W. F. Somerville of Glasgow reports a case of severe hysteria successfully treated by high-frequency currents. The case was one of several years' duration and the symptoms were such that on one occasion the abdomen was opened by a surgeon with every reason for expecting to find a perforating ulcer of the stomach. Eventually electrical treatment was resorted to with the happiest results. Mr. T. J. Bokenham contributes a paper on the Position of Oscillatory Currents in Therapeutics and raises some very important considerations which many who practise high-frequency treatment would do well to take seriously to heart. The "Archives" does not confine itself to Röntgen Rays, and accordingly Dr. D. Chalmers Watson of Edinburgh records some important experiments made to show the influence of diet on the structure and the functions of the thyroid gland. Meat diet is the one particularly referred to and some interesting conclusions are drawn. From 1875 to 1899 the importation of meat into the country rose from 18 pounds to 45 pounds per head per annum and also there was an increase of 24 per cent. in the amount of land under pasture during this period. Concurrently thyroid medication has been found useful in a number of conditions which have no known relationship to the thyroid gland. His explanation is that "as a result of an excessive meat dietary there has been established, and is being established, in many subjects an alteration in the character of the thyroid secretion. When this alteration takes the form of a simple deficiency of the thyroid secretion the defect can be remedied by administration of thyroid gland." The paper may be compared with one by the same writer, which appeared in THE LANCET of Feb. 11th, 1905, p. 347.

The Archives of Physiological Therapy. Edited by CLARENCE EDWARD SKINNER, M.D. New Haven, Conn. Boston, U.S.A.: The Gorham Press, Richard G. Badger. Subscription $3.00 (12*s.*) per year.—This is a new journal "devoted to the diagnostic and therapeutic uses of electricity, radiant energy, heat, water, mechanical vibration, &c.," which it is intended to publish monthly. In conjunction with the editor are some 20 others more or less well known in the medical and scientific worlds. All the original articles in this first number consist of papers read at St. Louis in September of last year when meetings were held at about the same time by the electro-therapeutic section of the International Electrical Congress, the American Electro-Therapeutic Association, and the American Röntgen Ray Society. Dr. Maurice Benedikt of Vienna supplies a contribution to the Radio-Diagnosis of Diseases of the Head and Brain. The author has evidently directed no little time and study to this highly specialised branch of x ray diagnosis and his paper will be found of great interest by x ray workers and others. Dr. W. J. Herdman offers some novel suggestions for the treatment of Dupuytren's and allied contractions by a modified form of electrolysis. Other papers by Dr. W. H. White on the Action of High-frequency Currents and Dr. J. H. Kellogg on Phototherapy in Chronic Diseases, &c., assist in making up a very interesting number. The second, and greater, half consists of a very complete set of reviews and abstracts of all the current literature bearing on the subjects comprised within its scope. This is a very valuable feature and if continued in the same thorough manner will do much to bring about the ultimate success of the undertaking. Good paper and clear type are used, while the illustrations are all that could be desired. This new journal has our good wishes for a prosperous and useful career which would seem already to be assured.

Ophthalmology. Vol. I., No. 3. April, 1905. Milwaukee, Wis.: H. V. Würdemann, M.D., and Nelson Miles Black, M.D. Pp. 209. A Quarterly Journal. Price per number $1.50 (6*s.*); per year, $5.00 (£1 1*s.*).—This journal is stated to be published as the result of the expressed wish of English-speaking ophthalmologists for a quarterly journal which would be printed without the intervention of a non-medical publisher whose interests must necessarily lie in pecuniary profit rather than in the advancement of medical science. *Ophthalmology* is owned, edited, and published by the medical profession. It contains original articles, abstracts from English and foreign works, and reviews. It has many distinguished names on its editorial staff. The present number contains the following original articles. 1. Epithelioma of the Eyelid removed by Dissection and X Ray Treatment, by Walter Hamilton Snyder, M.D. Toledo, Ohio. A coloured plate is appended to this communication showing a ragged tuberculated growth on the lower eyelid near the outer canthus. Eight applications of the x rays were made, after removal with the knife, for ten minutes at a time, at a distance of seven inches with a soft tube, between June 10th and July 28th, with excellent results. 2. On Peritomy for Diffuse Corneitis and other Affections of the Cornea, by Simeon Snell, F.R C.S. Edin., of Sheffield. Mr. Simeon Snell has practised peritomy in 200 cases of various forms of keratitis with much success. 3. Sarcoma of the Orbit with Report of Four Cases, by E Oliver Belt, M.D., Washington, D.C. 4. Elephantiasis of the Upper Eyelid, by H. Harlan, M.D., and R. H. Johnston, M.D., of Baltimore. The text contains a drawing of a case and of the microscopic appearances presented by sections of the swelling. 5. The Question of Iridectomy in Glaucoma Simplex, by Frederick E. Cheney, M.D., of Boston. The author thinks that theoretically it is advisable, especially at middle age and in patients with a melancholic disposition. 6. Intraocular Tuberculosis, with the report of Two Cases, by William Campbell Posey, M.D., of Philadelphia, with four figures in the text. 7. Some Remarks on Molluscum Contagiosum, by Dr. E. H. Oppenheimer of Berlin, with a figure in the text. 8. The Treatment of Pyogenic Infection of the Eyeball, by A. Maitland Ramsay, M.D. Glasg., of Glasgow. Dr. Ramsay recommends argyrol and collargol. There are numerous abstracts from contemporary literature in different countries.

Dublin Journal of Medical Science.—The May number is chiefly devoted to surgical topics. Dr. Henry Fitzgibbon speaks favourably of the treatment of syphilis by intramuscular injections of mercury and gives a formula for such use in which the metal is incorporated in a basis of lanolin and parolein. Dr. Charles Greene Cumston deals with suprapubic cystotomy in children and points out the special facility of the operation when performed at an early age. Mr. William Taylor records the notes of a case of gangrenous traumatic hernia successfully treated by resection of the necrotic portion of the bowel and Dr. James Craig narrates the sequel of a case of cured aneurysm of the innominate artery, the patient subsequently dying from rupture of a second aneurysm, affecting the aortic arch, into the œsophagus.

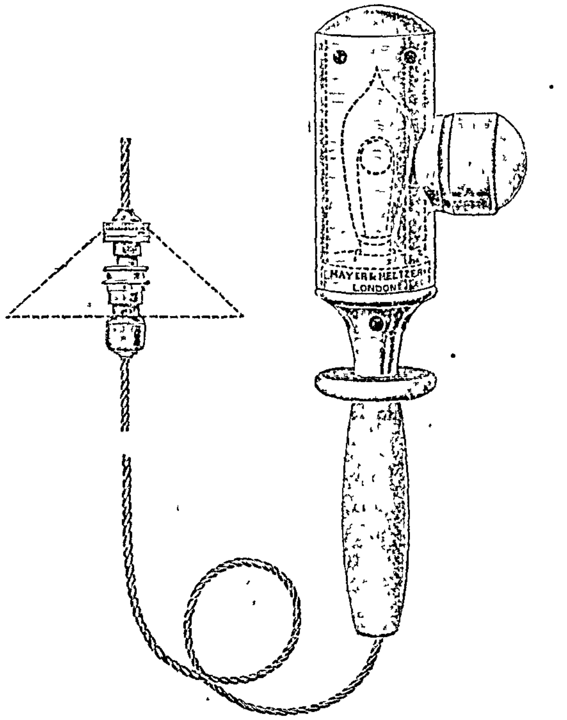
Scottish Medical and Surgical Journal.—The articles in the May number of this journal are of more than average interest. Dr. Horace C. Colman deals with the treatment of hæmoptysis and menorrhagia by inhalation of amyl nitrite and quotes some good results. The method is eminently scientific as it aims at diminishing the blood pressure at the bleeding point and thus imitating nature's mode of arrest of hæmorrhage by syncope. It is the exact contrary of the old irrational treatment of pulmonary hæmorrhage by ergot. Mr. Malcolm Campbell makes some interesting suggestions as to the connexion between ovarian disease and uterine fibroids, and Dr. R. Cranston Low contributes a useful paper upon the Employment of Tuberculin as a Means of Diagnosis; after a period of exaggerated fear to use this test there are now signs that it is coming once more into favour. Some notes on treatment with tuberculin are also given in this paper.

Edinburgh Medical Journal.—The May number of this journal contains the fourth Morison lecture on Insanity by Dr. John Macpherson in which is an interesting discussion of the toxic element in many forms of mental disease, an important conception which is coming to the front in this branch of medicine. Dr. W. Allan Jamieson draws attention to the value of pyraloxin, a modification of pyrogallic acid, in dermatology, and Dr. Frederick W. Price discusses the prognosis and treatment of early pulmonary tuberculosis in a paper which, though it contains nothing very novel, affords a useful summary of the subject. Mr. A. Francis Steuart, advocate, contributes an interesting historical sketch of celebrated trials for poisoning in Scotland up to the year 1625.

New Inventions.

A PORTABLE ELECTRIC LAMP FOR HOSPITAL USE OR FOR THE CONSULTING ROOM.

THIS lamp has been designed for the purpose of providing a cheap serviceable light and portable lamp for use where electric current is available, particularly in hospital wards, consulting rooms, or houses supplied with electric current from the mains. It consists of a small lantern fitted with a suitable electric lamp, fibre handle, bull's-eye condenser, flexible cord, and fittings. The lantern is kept cool by means of the air currents between the inner and the outer jackets. Its portability compared with those in present use and its advantages over cell lamps should commend it to those in particular who require portable lamps for general work. It was designed by Dr. J. Howard-Jones, medical officer of health of Newport, for use in the borough isolation hospitals, Newport (Mon.), and has been made by Messrs. Mayer and Meltzer of 71, Great Portland-street, London, W.



THE "ENGLEFIELD" BOOK SUPPORTS.

THE illustration represents a support on which books or paper may be held in an inclined position for the purpose of reading, writing, or drawing. In sitting at school desks while learning these arts children are very liable to acquire the habit of placing themselves in a stooping or round-shouldered position, to the injury not only of their figures but of their eyesight. In order to prevent this Mr. Englefield, who is the headmaster of the Gloucester municipal school of art, has devised two supports which are very portable and convenient in use, and which hold a book or paper at an inclination of rather more than half a right-angle—namely, about the ordinary slope of an artist's easel or a newspaper stand in a reading room. These supports are intended to stand on an ordinary table as shown and consist of two parts, one being the frame, measuring about 16 × 12 inches, which holds the book or the paper, and the other being an angular piece which gives the frame its inclination. The slope answers well for drawing and especially for holding a book which is being read but for ordinary quick writing most adults would prefer the paper more nearly level. The supports are in two materials—white deal (frame-shape for drawing), price 3*s.* 6*d.*; and birch wood (desk-shape), 6*s.* 6*d.* plain and 7*s.* 6*d.* stained and polished.

RICHTER'S NEEDLE HOLDER.

FROM the considerable number of patterns of needle holder which have been from time to time devised there is evidently some difficulty in combining all the requisite qualities in one instrument. Richter's needle holder presents some new features of construction and in it the clamping of the needle is not so likely to be disturbed when the grasp of the hand is tightened as in some other needle holders which we have seen. It is of superior finish and is made in four lengths—namely, 4½, 5½, 7, and 8 inches. The agent from whom it may be obtained is Mr. F. L. Anderson, 1, Furnival-street, London, E.C.

MEDICAL CROSS PURPOSES IN RUSSIA.—The recent decision of the Pirogoff Medical Society to abstain from coöperating with the Government committees in their struggle with the threatened cholera and stating that it is impossible for medical men to join such committees, &c., has raised considerable criticism in the Russian press. Now the Yaroslav medical men, to the number of 14, have sent a protest for publication to the *Novoe Vremya* because, as they allege, although anxious to follow the usual course and to have it published in the professional press, the *Russki Vrach*, to which it was sent, refused it hospitality. They protest, *inter alia*, that the Pirogoff Medical Society had no right to issue such a notice. The document closes with a formal protest against the resolutions of the Pirogoff congress as "arrogant and despotic, infringing our *rights* as medical men and citizens, and tending to set the members of the profession one against the other," &c.

CENTENARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

MONDAY, MAY 22ND.

A MEETING of this society commencing the proceedings in connexion with the celebration of its centenary was held on May 22nd, Sir R. DOUGLAS POWELL, the President, being in the chair.—Dr. Christian Bohr, Sir William Ramsay, Dr. Robert Barnes, and Dr. Walter H. Gaskell were admitted Honorary Fellows of the society.

Presidential Address.

The PRESIDENT then delivered the presidential address. He said: It is naturally expected that the President should address a few congratulatory remarks on the attainment of the hundredth birthday of this great society. Time only permits me to be very brief, for much has to be done to-day. I will therefore express on the part of the past presidents of this society now living—Mr. T. Holmes, Mr. J. Hutchinson, Dr. W. H. Dickinson, Mr. Thomas Bryant, Dr. F. W. Pavy, and Mr. A. Willett—and on the part of the council and myself our most hearty congratulations to the Fellows of the society on the completion of the hundredth year of its corporate life, our most hearty welcome in the name of the society to the distinguished Honorary Fellows and to the guests who honour us with their presence during this centenary celebration. The Royal Medical and Chirurgical Society was founded in 1805 for the purpose of conversation on professional subjects, for the reception of communications, and for the formation of a library. It was an offshoot from the Medical Society, the particular occasion for which could scarcely arise in modern times and from the effects of which that society soon recovered. In 1808, indeed, showing that no ill-feeling was left behind by the severance, a proposal emanated from our sister, or rather our parent, society for a reunion to form a new Society of Medicine. It is perhaps to be regretted that the union was not then effected, for a combination of the intellectual and material forces of the two principal societies in London would doubtless have been for the greater service of medicine. Might it not still be so? With the experience of the cause of this dissension, however, two very important resolutions were carried at the very first meeting of the Medical and Chirurgical Society under the presidency of Dr. Saunders, resolutions which have been in force ever since, were incorporated in the Royal Charter granted 30 years later, and have been adopted by most of the societies which have since arisen—viz., (1) "That no gentleman be eligible to the office of President or Vice-President for more than two years in succession;" and (2) "That a certain number of the council go out annually." The objects with which the society was founded have been pursued with vicissitudes of fortune but with a success which cannot but illumine our centenary retrospect with a glow of triumph and gratification and which sheds a bright prospective hopefulness and encouragement upon the future of our work. I have here a volume, which has, I hope, reached every Fellow, in which the chronicles of the society are most interestingly set forth by our honorary secretary, Mr. Stephen Paget, and which also contains a life sketch of each of the 50 presidents by our honorary librarian, Dr. Norman Moore. It is most instructive reading and I think the council has done wisely to sanction the publication of the volume and the society is indeed gratefully indebted to the able authors for the labour and interest they have taken in its production. These chronicles and records [illegible] the records of no previous century can compare. It would be tedious for me even to enumerate the subjects treated of; they are matters of medical history with which you are all very familiar. I would broadly characterise them as dealing in the first half of the century with many and great incidents of medicine and surgery and in the second with great developmental movements in pathology and the treatment of disease. Isolated cases and groups of cases of great intrinsic importance and, looking back upon them, of historical interest are brought forward in the earlier, and indeed in both, periods—many of them brilliantly suggestive but not to find place and fulfilment until the larger knowledge and quickened inventions of later times permitted. Amongst such cases and papers I would mention Astley Cooper's ligature of the common carotid artery, Dundas's description of acute rheumatic peri- and endo-carditis, and Abernethy's account of mitral stenosis, all in the first year of the society's formation. At the time when the Napoleonic wars were raging we were receiving papers on the health of the navy and army from our Fellow and later our President, Sir Gilbert Blane, whose introduction of lime-juice for the prevention of scurvy saved more lives and much more misery than were sacrificed or occasioned in all those cruel encounters. Sir B. Brodie in 1836, by his temperature records of a fatal case of luxation of the cervical vertebræ with destructive hæmorrhage into the upper cord, demonstrates what his earlier experiments of 1811 had led him to believe and as had been guessed at by John Hunter, that fever was neither a mere matter of altered circulation as the older physicians had thought, nor of oxidation as the physiologists after Lavoisier were teaching, but that it was dependent upon some other controlling factor probably of nervous origin. How otherwise could be explained a rise of temperature to 112° F. in a man dying with respirations reduced to less than six per minute? Here was the earliest use of clinical thermometry, fully to be established 25 years later by the careful labours of Wunderlich in Germany and Professor Ringer in this country. The clinical thermometer is now part of the pocket equipment of every nurse and is to be found in every household, yet I remember when its value was roughly challenged by one of the greatest physicians of the time. It was during Bright's presidency in 1838 that Bostock read his paper on the clinical examination of the urine and so initiated an important development of clinical pathology. Dr. Webster's paper in 1843 on the Brutal Treatment of the Insane then prevailing was the forerunner of the gentler and more humane methods which Conolly so nobly advocated. The paper by Hamilton Roe and Thompson in 1835 (preceded 14 years by a single case recorded by Dobson) on Paracentesis for Empyema was th[illegible] thoracic therapeutics. [illegible] Spirometer, John Mars[illegible] Bird and Hilton on an [illegible] in 1846-47, Kirkes on the [illegible] from the Interior of the Heart and their Mixture with the Circulating Fluid, and Spencer Wells's first five cases of ovariotomy a year or two later. These are amongst the more suggestive of the papers in the first half of the century, every one of which may be said to herald great future achievements in medicine. The latter half of the century has also had its epoch-making papers. But in the 50 years between 1840 and 1890 there were four great events in medicine which would mark out for distinction any century—viz., Marshall Hall's exposition of the reflex function of the nervous system; the discovery of a safe anæsthesia; the discovery and acceptance of the antiseptic system in surgery; and the growing recognition of the action of bacteria in the etiology and pathology of the acute specific diseases. These four great advancements in medical science crowded into the short space of 50 years have an interdependence that might form the subject of an interesting discourse, upon which, however, I have no intention to enter. This society has had something to do with them all and they have permeated and dominated most of its later and most brilliant records. Without anæsthesia, in the absence of antiseptic methods or their more recent aseptic developments, and without a knowledge of bacteriology no advance in visceral or joint surgery was possible, no further steps for the prevention of epidemic diseases could be formulated, the explanation of many intricate disorders of digestive and excretory organs was lacking, and their satisfactory treatment was impossible. Most of the initiators of these advances in medical science which have led up to and accomplished such great results are, or have been, Honorary Fellows of the society. The honoured names, Darwin, Pasteur, Marshall Hall, Villemin, Claude Bernard, Charcot, Lord Lister, Lord Kelvin, Koch, and others still living are indelibly written upon the pages of science in its beneficent relations to humanity. Many others on our Honorary [illegible] of our society are still [illegible] work. It might not be in good taste to [illegible]at they are well known to, and honoured by, us all. There are other papers not directly connected with these four eventful discoveries which are of great practical and historical importance. Samuel Fenwick's paper on the Microscopical Examination of the Sputum and Marcet's paper on the Inoculation of Sputum in the Diagnosis of Tuberculosis followed close upon Villemin's discovery of the inoculability of tubercle in 1865, preparing us 17 years beforehand for Koch's great discovery of the specific poison of that disease. Mr. Jonathan Hutchinson's paper on Vaccino-Syphilis in 1871 was of vast and far-reaching public importance. The report of a committee on the Hypodermic Use of Medicines in 1867 marked the time which, to some of us, may seem almost prehistoric when the hypodermic syringe was only coming into use. Dr. Ord's paper on Myxœdema in 1877 may also be especially mentioned. But the chief work of later years has undoubtedly been the development of visceral and especially of abdominal surgery, the necessary conditions for which did not previously exist. It was within the walls of this society that Spencer Wells in 1871 established the operation of ovariotomy which led up to so many further developments of ovarian and uterine surgery: and that Sir Frederick Treves in 1888 read his first paper on Relapsing Typhlitis treated by Operation: and it was here, too, that the operative treatment of appendicitis was brought up to date by a spirited discussion only a few weeks ago. I think that one of the attributes of our society which may give us most unbounded satisfaction is the magnificent library we have acquired. Much of this has been due to the liberality of friends in sending us their works and in presenting to us rare books which have come their way. But to the enterprise of the society and to the lavish expenditure of its scanty funds in former years it is chiefly due that we have perhaps the finest library of medical and scientific works in the world. I am not sure that the censure of our chronicler is all deserved for our illiberality with regard to publication of our proceedings in early years. For at that time the sale of our Transactions was a large source of our income provided by the work of our Fellows and wholly expended not upon themselves but upon new books for the library. The occasion and the practice have now long since passed. Perhaps the object which the society had in view at its first foundation second to that of acquiring a library—viz., the conversational discussion of cases and subjects of medical and surgical interest—has been least cultivated and perhaps amongst the amendments that must come in our proceedings in due time this point may be considered. Whatever future may be before us we can look back upon a vigorous past and a prosperous present. At no time has the position of the society been better recognised than to-day, at no time has its material prosperity been greater. I would suggest that a grateful thought for the many distinguished men who formed the councils of our society in the past and have carried it on to its present prosperity may fitly occupy our minds during this centenary. Nor should we forget the permanent officials of the society. We may some of us remember the genial courtesy of our late librarian, Mr. Wheatley, who spent the best years of his life at our former house in Berners-street; and to our friend, Mr. J. Y. W. MacAlister, with his business talent, wide knowledge, and zeal in the service of the society, we owe much of our present prosperity, whilst to his great energy and that of his staff of assistants in carrying out the wishes of the council and special committee is due the success which will, I hope, attend the celebrations which we commence to-day.

After the address Professor J. CHIENE on behalf of the Medico-Chirurgical Society of Edinburgh, Mr. JOHN LANGTON on behalf of the Medical Society of London, Dr. FREDERICK TAYLOR on behalf of the Clinical Society of London, Dr. ROBERT BOXALL on behalf of the Obstetrical Society of London, and Mr. CHARTERS J. SYMONDS on behalf of the Laryngological Society of London, congratulated the Fellows of the Royal Medical and Chirurgical Society on the attainment of the 100th anniversary of the foundation of the society.

Mr. JONATHAN HUTCHINSON proposed, and Mr. THOMAS BRYANT seconded, a vote of thanks to Sir R. Douglas Powell, which was carried unanimously.

The Banquet.

The Prince of Wales was the guest of the evening at the centenary banquet held at the Hotel Cecil on May 22nd. The chair was taken by Sir Richard Douglas Powell, the President of the Society, on his right hand side being the Prince of Wales and on his left the Duke of Northumberland. The company numbered about 480 and amongst those present were Lord Alverstone, Professor T. Clifford Allbutt, Sir Squire Bancroft, Sir T. Barlow, Sir W. H. Bennett, Mr. J. Bland-Sutton, Professor Christian Bohr, Sir Lauder Brunton, Sir W. J. Collins, Professor J. Chiene, Sir A. Cooper, Sir C. Cust, Sir G. Doughty, M.P., Sir Dyce Duckworth, Sir Arthur Conan Doyle, Sir J. Dewar, Sir W. Foster, M.P., Sir W. R. Gowers, Sir C. Holman, the Hon. S. Holland, Sir W. Huggins, Director-General A. H. Keogh, Dr. D. MacAlister, Sir A. R. Manby, Sir Patrick Manson, Professor Pierre Marie, Sir John Moore, Sir Shirley Murphy, Sir H. F. Norbury, Sir L. H. Ormsby, the Bishop of Oxford, Sir J. Paget, Sir G. H. Philipson, Sir W. Ramsay, Sir J. Reid, Sir A. W. Rücker, Sir F. Semon, Lord Strathcona and Mount Royal, Sir W. Taylor, Sir F. Treves, Sir J. Batty Tuke, Sir J. Williams, the Right Hon. John Morley, and the honorary secretaries, Dr. G. N. Pitt and Mr. S. Paget.

The toast of "The King" was proposed by the PRESIDENT and drunk with enthusiasm. This was followed by the toast of "Queen Alexandra, the Prince and Princess of Wales, and the other members of the Royal Family," which was proposed by the PRESIDENT in felicitous terms and was acknowledged by the PRINCE of WALES who, upon rising to reply, was greeted with hearty cheering. The wonderful carrying power of the voice of His Royal Highness and his excellent elocution were well exemplified in the large hall in which the banquet was celebrated. The PRINCE of WALES said:—

My Lords and Gentlemen,—I am greatly touched by the words of Sir Richard Douglas Powell, and in the name of the Queen and the Princess of Wales and the other members of my family, and on my own behalf, I heartily thank him for the sentiments to which he has given expression and this distinguished assembly for the kind manner in which they have received this toast. I am very happy to be present on this occasion, memorable in the history of the Royal Medical and Chirurgical Society, when we celebrate to-night on the exact date, May 22nd, the anniversary of the day on which this society was founded just 100 years ago. I consider it a great honour to have been enrolled among its honorary Fellows and to be associated with the names of men eminent both in our own nation and in almost every other nation of the world. And I am very pleased to meet some of them here to-night. It is a further satisfaction to me to be identified with a society with which my family has been connected ever since its incorporation by Royal Charter in 1834. Sir Richard has kindly referred to my position as President of King Edward's Hospital Fund for London. I regard it as a precious trust transmitted to me by the King—its founder; and I shall always endeavour to the best of my power to further its work, the gradual but steady development of which I watch with keen interest and satisfaction, for it is my firm conviction that there is no better way in which we can help our poorer brethren and sisters than through the healing work and humanising influences of our great hospitals. With regard to the Imperial Cancer Research Fund I am glad to say that we are working in close touch with similar undertakings in other countries. Considerable and valuable results have been attained during the past year, and I trust that we may look forward to the day when medical and surgical knowledge will have unravelled the mysterious cause of this terrible disease and have acquired the power to deal successfully with it. I must congratulate this famous society on celebrating the 100th anniversary of its foundation. In spite of its years it is still full of the vigour, enterprise, and enthusiasm of youth. The advances which have been made in the science of medicine and surgery during the last 100 years are almost without a parallel in the history of human progress. During this period physiology has been established as a precise branch of learning, while the new science of bacteriology would seem to have laid bare the very foundations of disease. Antiseptics and the clinical thermometer have been invented, and methods of investigation introduced of which, I am sure, the medical profession of 1805 had never even dreamt. In the foundation of antiseptic surgery by Lord Lister this country can claim one of the greatest achievements in the cause of humanity. In the sphere of public hygiene nothing short of a revolution has been effected. Our hospitals, which 100 years ago were little more than mere refuges for the sick, have become institutions in which the most beneficent treatment is carried out with scientific thoroughness. With

this great century of progress this society has indeed been actively concerned and it can look back upon its record of 100 years with the assurance that it has taken no little share in a memorable scientific advance Its deliberations can
only result in a medicine and
surgery and in man suffering
With it also re passing judgment upon new projects and new theories, of directing investigation into right channels, and of keeping a jealous watch upon the scientific reputation of a great profession I feel confident that the Royal Medical and Chirurgical Society will maintain this trust as faithfully in the future as it has in the past I heartily wish the society every continued prosperity Gentlemen, I am most grateful for the hearty welcome you have given me and I assure you it has given me the greatest possible satisfaction and pleasure to have come here this evening and to be present on this memorable occasion

The PRESIDENT then proposed the toast of "The Society He said that His Royal Highness the Prince of Wales had already alluded to much of the work which had been performed by the society in the past 100 years and it was more fully described in the chronicles now in the hands of every Fellow of the society and in the personal records of the presidents of the society sketched by Dr Norman Moore In those chronicles were contained accounts of all the difficulties that the society had experienced and of its growth till it had arrived at the distinguished old age of 100 years In these chronicles were faithfully reflected the history of medicine in the past 100 years The society was founded in 1805 with Saunders as its president, the objects of the
e conversation on subjects of
or the reception of communi
[illegible] world, and for the formation of a library Amongst the men who established this society were Abernethy, Babington, Blane, and Cooper At first the society existed merely as a symposium for discussion of matters of mutual interest Then papers were received and by degrees a library was formed Premises for the society were acquired at first on a humble scale and then in 1834 a house was taken in Berners street which was occupied by the society for about 50 years In 1834 the society received its Royal Charter and in that year King William IV became its patron and it has enjoyed the patronage of the Royal Family ever since that time and to day it had the additional distinction of adding the name of the Prince of Wales to the roll of its honorary Fellows The society now possessed a library of some 50,000 volumes, with the journals and proceedings of every learned society throughout the world No advance in medicine or surgery had taken place which had not been promoted by this great society The Prince of Wales had enumerated the many momentous advances in medicine which the society had been the means of bringing to light In the first half of the century single instances appeared as streaks of light that usher in the dawn of great movements and discoveries In the latter half of the century there were important accessions to medical knowledge, the first was the attainment of a safe anæsthesia, secondly, there was the establishment of the antiseptic methods to which the Prince of Wales had already alluded, and thirdly, there was the recognition of the bacterial origin of specific disease There was no necessity to discuss the history of these great and fruitful advances in medicine which were as familiar as household words, so much so that to describe what went before them now seemed an excursion into the dark ages of prehistoric times Without anæsthesia deliberate surgical procedures would be impossible and without antiseptic methods intestinal surgery could not be undertaken It would be almost impossible to reckon up the number of lives that had been saved and the amount of suffering that had been spared by the daily operations that were now performed, not one of which would have been possible 35 years ago Lord Lister 35 years ago, by his researches revolutionised surgery In 1859 pyæmia accounted for something like 42 per cent of deaths in amputation cases, at the present time the disease was scarcely known In the history of ovariotomy was found typified the vast progress of internal surgery In the 'sixties ovariotomy was protested against as being too fatal and the operation was only established in 1871 in the rooms of the Royal Medical and Chirurgical Society by the strenuous and courageous advocacy of Sir Spencer Wells In 1871 the mortality accompanying the operation of ovariotomy was 22 per cent by the year 1881 when the teaching of Lord Lister had been well established the mortality had fallen to 4 per cent, and at the present time was less than that Anæsthetics and antiseptics had alone rendered this achievement possible and it was typical of the advances that had taken place in every department of surgery Continuing, the President stated that in his student days the exact causes of acute diseases like lockjaw, cholera and typhoid fever were not known At the present time it was possible to depict upon the screen the particular organism which was responsible for each of those diseases They could detect the organisms and knew their habits food, virulence, and manner of growth There were certain persons who grumbled at the cost of hospital administration and at the expense of medical attendance but when the conditions of practice in those days were contrasted with the medical and surgical practice of the present day then it had to be admitted that the labour and thought of a century had not been thrown away The rates of mortality had steadily fallen in consequence of the work of medical men engaged in the prevention as well as the cure of disease So perfect was sanitation becoming that the time was rapidly approaching when medical men would be able neither to live nor to die The members of the Royal Medical and Chirurgical Society could be forgiven for a certain amount of jubilation on the unique occasion they were celebrating but in their hearts they were mindful that much remains undone They were aware of opportunities that had been lost and they remembered the strenuous labours of sister societies They were humbly mindful of the increasing responsibilities of the next century and they were solicitous of succeeding by uniting the forces that now overlapped in advancing to higher realms of achievement

Dr PYE SMITH then proposed the toast of Literature and Science' He observed that there had ever been a close connexion between the medical profession and literature In that golden period which intervened between the Wars of the Roses and the Reformation there were four men who directed the new learning and the national education Their names were Erasmus, Sir Thomas More Dean Colet and Linacre Linacre was the founder of the Royal College of Physicians and was an eminent Greek scholar He was followed by Dr Caius of Cambridge and Datchet In the seventeenth century the medical profession contributed to literature an author of the first rank—Sir Thomas Browne who wrote 'Religio Medici Pseudodoxia Epidemica, 'The Garden of Cyrus, and 'Urn Burial' An eminent physician once said that Sir Thomas Browne was a more important man than his contemporary the great Harvey, because if Harvey had not discovered the circulation of the blood somebody else would certainly have done it whereas if Browne had not written the Religio Medici" no one else could In the following century the great literary physician was Arbuthnot who was the friend of Swift, of Pope, and of Gay Arbuthnot contributed three of the greatest satires to our language 'The History of John Bull,' 'The Conduct of the Allies and "The Epitaph on Colonel Charters' After the death of Arbuthnot who died, it was feared from cirrhosis of the liver, Pope confided the care of his health to the great Dr Mead, the collector of the finest library of the period and also to the great anatomist and surgeon Cheselden both of St Thomas's Hospital, and Pope did what it was often wished the patients of the present day would do—he took what Mead and Cheselden advised Johnson found a friend and physician in Heberden, whom he called 'Ultimus Romanorum,' the last of the learned physicians Those who read Heberden's Commentaries must still be struck with the conciseness of his style the perfect clearness of his language, and the abundance of his good sense Johnson himself in his Lines on the Apothecary Robert Levet has portrayed the humble but useful life of the general practitioner and thereby has proved his title to the name of poet A medical writer who was also of high literary merit was Sir Thomas Watson His art in telling cases was remarkable They still had learned physicians amongst them There were Dr J F Payne, the Harveian Librarian, and Dr Norman Moore who told sad stories of the deaths of kings And they still had learned surgeons, there were Mr Tweedy (President of the Royal College of
Paget, and Mr D'Arcy Power
a relaxation, a refreshment, and
he art of medicine depended for
stence upon science By science
they had reached the present condition of progress and by

science alone persistently and ungrudgingly pursued they would reach new successes in the prevention and cure of disease. How scientific the whole bent of medicine was was proved not only by the broad stream of authors like Harvey, Hunter, Jenner, Bichat, Laennec, Claude Bernard, Chauvaux, Johannes Müller, Ludwig, Pasteur, and Lister, but also by the fact of many medical men who excelled in other branches of science—men like Gilbert whose great work on the magnet had lately been re-published by Sylvanus Thompson; men like Mayow, a young Oxford doctor, who in his short life established the mechanism of respiration and discovered the existence of oxygen. There was also Thomas Young, physician to St. George's Hospital, who published the undulatory theory of light, deciphered the Rosetta stone, and earned the unstinted praise of Helmholtz—a praise, however, which had not been denied him by his own countrymen, as the great German supposed. Science was the very breath of life to medicine and investigations must continually go on. Encouragement was not wanting, for much had been done towards the prevention of diphtheria, of malaria, and of many tropical diseases since a royal critic asked the question, Why preventable diseases were not prevented? They all gratefully acknowledged the interpretation given by the eldest son of England to the ancient motto of the Black Prince, "*Ich Dien*," by serving on the council of the association formed for the purpose of studying the origin of, and in time it was trusted the prevention of, that terrible disease called "malignant."

Sir ARTHUR CONAN DOYLE acknowledged the toast. He remarked that the fact that he was chosen to respond was the latest illustration of the rule that in this country it was the understudy who had always had to do the hard work. He wished that Mr. John Morley had taken the task of replying on himself. He had been given to understand that his name was coupled with the toast because he was a medical man. That was true, but an unkind critic had added that no living patient of his had ever been seen. There was, however, one little corner of the subject on which he might be permitted to make a few remarks. Some authority had been lately examining the law as it was found in novels and had concluded that the novelist's law was almost more strange than the law with which they were all familiar. According to the novelist if a man died intestate his property went to the nearest villain, but however that might be if the law of the novelist was strange the medicine of the novelist was still more so. In novels only a few diseases were recognised and those were all to do with the upper part of the body, for no novelist ever hit below the belt. The symptoms of diseases and their treatment were very simple in novels. The patient who went into a decline was most useful in fiction and the successful treatment of such a case was the reappearance in the last chapter of the splendid hero who had been so grossly misunderstood in one of the earlier chapters. Often with this extreme wasting the novelist coupled an almost ethereal beauty but the disease that was most useful to a writer of fiction was undoubtedly fits—whether apoplectic or epileptic mattered little to the novelist. The point was that the heavy and stertorous father was always eventually carried off in a fit, often falling down with a pen in his hand in front of an unsigned will. That was an exceedingly effective situation. And then, again, there was that mysterious malady known in novels as brain fever. That was a wonderful disease and exceedingly useful for many purposes. As novelists only possessed a few diseases they were anxious still to have the use of them. The irascible parent always afflicted with gout in the ball of the great toe was one of the novelist's most necessary puppets. The writers of fiction, however, claimed to be kindly disposed towards the medical profession and always portrayed the village practitioner as a most worthy person and depicted the visit of the solemn consultant from London without undue malice.

Sir WILLIAM HUGGINS (President of the Royal Society) was also intrusted with the task of acknowledging this toast. He said that the Royal Society had for two and a half centuries with untiring energy strenuously pursued the objects for which the society was formed—namely, the pursuit of natural knowledge; he did not consider that it was inappropriate for the Royal Society to be represented on that occasion, for the connexion between the Royal Society and the medical profession had always been an intimate one. Among the original members of his society were many physicians and surgeons and its roll had always contained many names of men distinguished in the medical profession of whom some had been presidents of his society, amongst whom he might mention the name of Huxley and last, but not least, his immediate predecessor that great man Lord Lister, who by the introduction of scientific methods into surgery had rendered comparatively safe operations which before were accompanied by very grave risk and had made possible operations which before could not have been entertained. Lord Lister was a man not only honoured by his own countrymen but also by mankind throughout the wide world. Happily the time had long passed when medicine and surgery were in the hands of illiterate people and quacks, but nevertheless in comparatively modern times the paralysing idea had prevailed that the living body was an enchanted ground outside the sway of physical and chemical forces where vitality reigned supreme and was all in all. The wonderful progress, however, of the art of healing in modern times had followed closely on the advances made in chemistry and physics. Medicine had been raised to the position of an exact science by the introduction of the accurate methods of physics and chemistry into the medical schools. It might be considered that medicine came wholly under the dominion of science when the true principles of the conversion of energy were found to hold good in regard to living things; in other words, the discoveries of science by bringing into medicine the use of physical methods and forces had diminished disease and prolonged life. Among these discoveries was the great work of Darwin which filled the intellectual world with new life. The investigations carried out by the Royal Society in regard to certain deadly diseases seemed to show that it was in the power of man so to control the conditions of the propagation of disease as to make it possible for Europeans to live and work in parts of the earth where hitherto the sacrifice of health and life had been lamentably great. The progress of medicine over disease had followed improvements in investigating natural knowledge and in the future they must look for the more intimate acquaintance of nature to secure further triumphs over disease and premature death, ultimately bestowing on man a longer and a fuller life.

The toast of "The Visitors" was given by Mr. H. T. BUTLIN, who referred first to the chief guest of the evening, His Royal Highness the Prince of Wales, to whom they were indebted for his presence there that night and also for honouring the society by becoming one of its honorary Fellows. The Prince of Wales was the first Royal honorary Fellow of the society and it had taken it 100 years to achieve that honour. Everyone, however, would admit that the time had not been ill spent. Mr. Butlin said that he envied the Prince of Wales much but he envied him most because he had heard him better than any person who had spoken in that room that night. Mr. Butlin then went *seriatim* through a list of the principal guests, beginning with the Duke of Northumberland, who responded to the toast.

The Duke of NORTHUMBERLAND, in replying, said that there were four great professions in this country which stood at the head of all other professions—the navy, the army, the medical, and the legal professions. They were respected and valued but no one wished to avail themselves of their active services if they could help it. Although, however, in one sense they did not wish to avail themselves of the services of these professions, in another sense they did; there was the preventive side in all these services and everyone felt safer in consequence of the care bestowed on the preservation of the common interests. Though that side of their work was less known to the world than their more showy and observable deeds, still at the same time everyone was conscious of the debt that was owed to them and to none of the services was a greater debt owed than to the science, the energy, and the devotion which were expended on preventive medicine by the medical profession. The Duke of Northumberland concluded by saying that, however incompetent any of the guests of the society might be, there was not one who was not fully alive to the value of the researches carried out by the medical profession and every guest was anxious to aid in every way the great work which the society and the medical profession had so magnificently discharged in the last 100 years.

Lord ALVERSTONE (the Lord Chief Justice of England) then submitted the toast of "The President." He commenced by warning Sir Arthur Conan Doyle that in his remarks upon the law he had forgotton that the Prince of Wales was a member of the House of Lords and he cautioned him to be more careful in future. The occasion on which they met that night was unique. Previous speakers had spoken of the work of this great society and had referred to the changes in medical science during the last century, but it was remarkable that that evening also put on record a new coincidence—namely, that the President of the Royal Medical and Chirurgical Society was a gentleman who was also President of the Royal College of Physicians. He felt that the great position which Sir Richard Douglas Powell held in the medical profession rendered any words from him unnecessary and when they remembered the great predecessors in his office, Sir James Watson and Sir William Jenner and Sir William Church, he felt sure that the position of Sir Richard Douglas Powell was one which commanded the respect of all and would induce them all to give the toast which he proposed a most hearty welcome.

The PRESIDENT, in replying to the toast, thanked the honorary secretaries who had so successfully worked for the banquet and acknowledged the services of the secretary of the society, Mr. J. Y. W. MacAlister.

The Prince of Wales having retired from the banqueting hall the very successful proceedings came to an end.

TUESDAY, MAY 23RD.

The Marshall Hall Address.

Sir R. DOUGLAS POWELL, the President, being in the chair,

Dr. HENRY HEAD, in commencing his address, said that the society met that evening to celebrate the 100th anniversary of the Royal Medical and Chirurgical Society and at the same time to pay a tribute to the memory of Marshall Hall. *To him they owed the first accurate conception of* what was known as reflex action. Dr. Head then introduced the subject of his oration, the Afferent Nerves under a New Aspect, and said he hoped to [illegible] always existed between the [illegible] and those which belonged t[illegible] sympathetic system. Certain [illegible] body could be found to belong to the same system as those which supplied the internal organs. In addition he hoped to show that the skin and subcutaneous tissues possessed sensory nerves which did not exist elsewhere. To these two systems was added a third set of afferent fibres which ran for the greater part with the motor nerves but separated from them at last to enter the spinal cord by the posterior roots. It was the impulses conveyed by these three sets of nerves which were sorted in the central nervous system into [illegible] (a) touch, (b) pain, and [illegible] Division of a peripheral [illegible] total loss of sensation over the greater part of the index and middle fingers and over part of the thumb on its palmar aspect. In addition, sensation was partially lost over a larger area. This area of partial loss was in reality one of complete insensibility to certain stimuli, such as light touch, intermediate degrees of heat and cold, and to the two points of the compasses. When the hand had settled down after the shock of the injury that had divided one or more of the nerves of the palm it was found that although the area corresponding to the nerve divided was totally insensitive to certain higher forms of stimulation a stimulus producing pain—e g., a prick of a pin—caused a more unpleasant effect than over normal parts. Recovery of sensation after complete division of a peripheral nerve began with disappearance of the analgesia and with the return of sensation to the extreme forms of temperature. But the hand remained exactly as insensitive as before to the higher stimuli such as light touch. It was to the condition of the hand at the stage of recovery that he particularly wished to draw attention. It might have been inferred that with the gradual disappearance of analgesia an improvement would follow to the higher forms of stimulation. This was not so. The boundary at which light touches were lost might remain as definite for many months as in the days immediately following the injury, although sensibility to pain, to heat, and to cold had vastly improved. The characteristics of a part which had become sensitive to prick and to the extremes of heat and cold were (1) that the sensation radiated widely, was referred to remote parts, and could not be accurately localised; (2) a prick produced a more unpleasant sensation than over normal parts; and (3) the sensation produced gave no measure of the intensity of the stimulus by which it had [illegible] of the area [illegible] as heat and [illegible] minute areas (hot and cold spots), each of which could be stimulated by heat or cold alone. This form of sensation was designated protopathic sensibility. After the affected part had remained for a variable period in this condition it began to become sensitive to light touches and the intervening degrees of te[illegible] from one anot[illegible] again became [illegible] more nearly normal and the widespread radiation so characteristic of the first stage of [illegible] by an increased accuracy of [illegible] bility was designated "epicr[illegible] ciated with the localisation and discrimination of cutaneous stimuli. A third form of sensibility was investigated in a case of complete experimental division of the radial and external cutaneous nerves at the elbow. After the radial half of the arm and back of the hand had been rendered totally insensitive to cutaneous stimuli the denervated parts of the hand remained sensitive to pressure or to any stimulus that deformed the subcutaneous structures. Localisation of those stimuli which could be appreciated was remarkably good. The fibres upon which this sensibility depended must run with the motor nerves. This form of sensation was designated "deep sensibility." The existence of this deep sensation depended on a separate system of fibres which ran with the nerves to voluntary muscles. Protopathic and epicritic sensibility probably depended also on two separate sytems of nerve fibres for the following reasons: (1) occasionally, after division of a peripheral nerve sensibility to pain, to ice, and to 60° C. might be abolished, but that to light touch and to water at [illegible] C. remained; and (2) after complete division of a ner[illegible] before epicritic, wherea[illegible] lete destruction of the [illegible] eturned *pari passu.* Evidently the two systems regenerated with unequal facility, the "protopathic" system regenerating more rapidly and with greater ease than the "epicritic" system. A part deprived of its nerve-supply was liable to injuries and the sores and ulcers so produced healed slowly. Such sores healed rapidly and permanently as soon as protopathic sensibility returned to the part, even though all epicritic sensation was still absent. The growth of nails was materially diminished by want of movement, deficient blood-supply, and muscular paralysis. It was a well-known fact that the nails did not grow as rapidly on the hand after the nerves had been divided, but by a series of observations extending over four years it had been shown that this was not due directly to the absence of any nutrition stimulus in consequence of division of the nerve but rather to want of movement associated with those vascular changes which were always liable to occur after division of a peripheral nerve. Every peripheral afferent nerve to the limbs contained protopathic and epicritic fibres. Towards the periphery the latter tended to fall into certain groups and the area supplied by each group did not overlap that of another group materially. The protopathic fibres, on the contrary, overlapped to the greatest amount on the periphery of the limb. This overlapping became less as the posterior roots were approached, showing that these fibres still maintain to a certain extent their segmental arrangement. The threefold arrangement of deep, protopathic, and epicritic sensibility ceased in the central nervous system at the first cell junction. The impulses conducted along these three lines became sorted out into paths for light touch, for localisation and stereognosis, for pain, for heat, and for cold. With regard to sensibility of the viscera, observations on the application of temperature stimuli to the intestine seemed to show that its sensibility resembled that which, in the skin, has been called protopathic. But it is entirely insensitive to all those stimuli which evoke epicritic sensation. In conclusion it was suggested that the body within and without was supplied by afferent nerves which belonged to the protopathic system. This could be divided into somatic and splanchnic; the latter included all that had previously been known as the afferent sympathetic. The protopathic system was peculiarly associated with the reflexes and with feeling tone (pleasure and pain). The sensations evoked from it in answer to appropriate stimuli were widely diffused and [illegible] frequently referred to parts at a distance. The f[illegible] greater ease a[illegible] those of the motor [illegible] retained to a considerable degree its original segmental arrangement. The external surface of the body and limbs were innervated by a second system of fibres which has been called epicritic. This system is of later development and regenerates more slowly than the protopathic. It was peculiarly associated with the localisation and discrimination of cutaneous stimuli. All subcutaneous structures were also innervated from afferent fibres that end in organs peculiarly susceptible to pressure. These fibres in the limbs and body wall ran in conjunction with the motor nerves to voluntary muscles and this deep sensibility was not materially diminished by the destruction of the sensory nerves to the skin.

A vote of thanks to Dr. Head was proposed by Dr. D. FERRIER, seconded by Dr. W. H. GASKELL, and carried unanimously.

WEDNESDAY, MAY 24TH.

The Conversazione.

A conversazione, largely attended by Fellows and their friends, was held at the Natural History Museum, Cromwell-road, on May 24th. The guests were received by the President of the society, Sir Richard Douglas Powell, and Lady Powell in the Central Hall. Amongst those present were the Duke of Northumberland, Lord Strathcona and Mount Royal, and Señor Manuel Garcia, the last named taking great interest in the model of the gigantic diplodocus which was displayed in the Reptile Gallery. Señor Garcia did not stay more than an hour but managed, with the help of Dr. W. Ewart, to see a great deal of the exhibits in the museum. The band of the Royal Artillery played in the Central Hall and the Meister Glee Singers drew a large audience, their rendering of "The Old Folks at Home" attracting especial attention. A large number of those present were shown round by Professor Ray Lankester who spared no pains in explaining the interesting treasures of the museum.

An Historical Exhibition.

A small but highly interesting historical exhibition was formed in connexion with the centenary celebration of the society. This exhibition was held at the society's rooms during Monday, Tuesday, Wednesday, and Thursday from 11 in the morning until late in the afternoon and the opportunity so afforded for inspection was taken advantage of by many medical men.

Looking Back.

As the centenary of the Royal Medical and Chirurgical Society has been celebrated this week we have thought it appropriate to reprint the following extracts from THE LANCET recording the receipt by the society of its charter of incorporation, and reporting the annual meeting held in the society's jubilee year, when, curiously enough, the question happened to be raised of excluding THE LANCET from the society's library. We wonder what the speakers would have said if it had been suggested to them that 50 years later one of the Editors of THE LANCET and the editor of the *British Medical Journal* would be members of the Council of the Society.

From THE LANCET, SATURDAY, SEPT. 6TH, 1834.

MEDICAL CHARTER.—(*From a Correspondent.*) It is no small proof of the progress of liberal opinions, that the *Medico-Chirurgical Society* have, *without opposition*, obtained from the present Government a charter of Incorporation. In due time the history of the intrigues by which an application for a similar charter was defeated under a Tory administration will be made public. The facts came out before the medical committee, and are recorded in the evidence. The President of the College of Physicians was the chief opponent of the Society, and his reasons for interfering were grounded on an impression that his College would in some way be affected by the existence of a chartered medical Society which held its meetings so near his own door.

From THE LANCET, SATURDAY, MARCH 10, 1855.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

JAMES COPLAND, M.D., F.R.S., PRESIDENT.

ANNUAL MEETING.

THURSDAY, MARCH 1ST.

The annual meeting was held this day, the President in the chair. The Report of the Council showed that the Society was in a prosperous condition. The following gentlemen were elected office-bearers for the session 1855-56 :—

President: Cæsar H. Hawkins.—*Vice-Presidents:* George Cursham, M.D.; William Baly, M.D., F.R.S.; George Busk, F.R.S.; Fred. Le Gros Clark.—*Treasurers:* Joseph Moore, M.D.; Thomas Blizard Curling, F.R.S.—*Secretaries:* Thomas Bevill Peacock, M.D.; H. Spencer Smith.—*Librarians:* Wm. Wegg, M.D.; James Dixon.—*Other Members of Council:* Henry S. Dyer, M.D.; Henry Bence Jones, M.D., F.R.S.; Thomas H. Silvester, M.D.; Theophilus Thompson, M.D., F.R.S.; Charles West, M.D.; James Moncrieff Arnott, F.R.S.; Charles Brooke, F.R.S.; John Eric Erichsen; Henry D. Jones; John Simon, F.R.S.

The following resolution was also carried :—

> "That no resolution carried
> amendment, at the annual ge
> respect to the election of the Co
> usual business of such meeting,
> notice shall not have been gi
> meeting, shall be binding on the Society or Council, until such resolution shall be confirmed by a special general meeting, to be convened within fifteen days of the meeting, at which such resolution shall have been carried, by notice from the Council, stating the object of such meeting, and the resolution or resolutions to be proposed for confirmation, and such notice shall be sent to all the Fellows at least five days previous to such meeting, and no question shall be discussed at such meeting, of which notice shall not have been given in the summons."

When the report of the Council had been read, an attempt was made by Mr. de Morgan and Mr. Ancell to show that the reading of that document was not part of the proceedings of the annual meeting, and that therefore an amendment might be made upon its reception. A long, desultory, and somewhat exciting conversation followed, in which amendments and motions were made and withdrawn, with the view, on the part of the proposers of discussing again the proposed withdrawal of THE LANCET from the library. Dr. Copland objected to any resolution upon the subject, and refused to put one, stating that the subject had been disposed of by the Council, which had been delegated by a public meeting to do so. Besides he, as chairman, would not allow a fresh contest between the partisans of opposition journals: that was not the place to fight such battles. He should therefore resist any attempt or subterfuge by which the contest could be renewed. Eventually the report of the Council was read, and Mr. Ancell then proposed an amendment to the effect, that as it had not referred to the proceedings respecting THE LANCET, it was unsatisfactory and incomplete. Mr. de Morgan then entered into a lengthened complaint against the Council, and said that it was only on the conviction that they would have acted differently from what they did, that he supported the proposal of Sir Benjamin Brodie, at the special meeting. Mr. Rowdon also spoke, and complained bitterly of the conduct of the Council. Mr. Travers begged of the Fellows not to continue to agitate political questions in the Society; they were quite foreign to its objects, and calculated to ruin the Society. He strongly reprobated such discussions as he had been listening to, and said that it was absurd to attempt to exclude one journal in particular. There was nothing to choose between them; one was as bad as the other. Eventually the amendment of Mr. Ancell was rejected by a majority of fifty-nine to twenty-four, and the meeting, after some routine business, broke up.[1]

---

[1] See also THE LANCET, March 11th, 1854, p. 270.

SOCIETY FOR THE STATE REGISTRATION OF TRAINED NURSES.—The third annual general meeting of this society will be held at the Medical Society's rooms, 11, Chandos-street, Cavendish-square, London, W., to-day (Friday, May 26th) at 3 P.M. Item No. 5 on the agenda is an address by Mr. R. C. Munro-Ferguson, M.P., on Parliamentary Procedure in Relation to the Passage of Bills into Law.

HOSPITAL FOR EPILEPSY AND PARALYSIS, &c., MAIDA-VALE.—The annual meeting of the supporters of this hospital will be held at the new hospital, 4, Maida-vale (near the end of St. John's Wood-road), at 3 P.M., to-day (Friday, May 26th). The chair will be taken by the Right Hon. the Viscount Clifden, Vice-President. The committee of management states that the first section of the new hospital has now been erected, furnished, and fitted at a cost exceeding £25,000 and that the experience of the past 12 months shows that some £2000 will be needed to meet each year's expenditure.

THE LANCET.

LONDON: SATURDAY, MAY 27, 1905.

The Centenary of the Royal Medical and Chirurgical Society.

THE Royal Medical and Chirurgical Society of London has fitly crowned a century of useful work by the varied celebrations which have covered several days of the past week and which have happily blended the pleasures of society with the pursuits of science. The gracious consent of His Royal Highness the PRINCE OF WALES to accept the Honorary Fellowship of the Society, his presence at the banquet on Monday evening, and the appreciative speech in which he sketched the progress of medicine since 1805, all indicate the favour with which His Majesty the KING and the Royal Family have long been known to regard the efforts of those who are most active in the conduct of the unceasing battle of the medical profession against disease and suffering; while the auspicious occasion was further graced by many distinguished representatives of other forms of learning. The Marshall Hall prize address by Dr. W. HEAD, on the Afferent Nerves Under a New Aspect, resting as it does partly upon his own labours and partly upon investigations carried out in conjunction with Dr. W. H. R. RIVERS and Mr. J. SHERREN, was in complete accord with the best traditions of the society in being a paper in which conclusions of far-reaching importance were based upon an adequate number of carefully selected facts; and the President's reception at the Natural History Museum, to which, as to KEMBLE'S acting, "the Graces lent their zone," afforded fitting evidence that even Science regards her triumphs as incomplete until they have been confirmed by the smiles of beauty. It was written of ROBERT ADAIR, a surgeon who flourished when the society was young and whose name would probably be found in the lists of the early members, that he was "the favourite of princes, of fortune, and of women," and the events of the past week go far to show that something of the same kind might be justly said of the society itself. May it long continue both to deserve and to receive such encomiums as those which have now been lavished upon the past 100 years of its existence.

It is one of the privileges of journals to have long memories and those who, like ourselves, can look back into the history of the past will recall at least some occasions on which differences of opinion among the Fellows of the society have been expressed with a force which might almost be said to border upon acrimony. The publication, for example, of a book on ulceration of the cervix uteri, with the stress which was therein laid upon the speculum as an essential instrument of diagnosis, was one of the now almost forgotten events which divided the society into two camps, and which brought large attendances to the meetings. A member of the society vigorously condemned both the new practice and its adherents, whether the latter were members of the medical profession or great ladies who zealously maintained the necessity of the inspections to which their sex were asked to submit. On another occasion the Fellows of the Royal College of Physicians of London assembled in their strength on a ballot evening for the purpose of recording their votes against the admission into the society of a distinguished provincial practitioner who had obtained the degree of Doctor of Medicine from the University of London and who established himself as a "physician" without seeking the sanction of the College. Such episodes, however, were few and transient and the operations of the society as a whole were as cordial in their character as they were eminently advantageous to all who took part in them. The papers read were usually founded upon long and extensive experience or upon carefully conducted research, and the society resembled the House of Commons in this, that the possessors of every kind of knowledge were to be found within the ranks of the customary audience. No speaker could fall into grave error without eliciting reply from someone who was both capable of correcting him and not unwilling to undertake the task; and hence the debates afforded lessons of caution to all who took part in them. It frequently happened that communications read before the society contained the first notices of new discoveries, some of which did not at the time receive full recognition of their importance, and among these was the paper containing the earliest description of embolism as a pathological process. The author, it was said, described how little pellets of fibrine could be shot off the valves of the heart along the arteries until they were arrested by diminished calibre and so blocked the vessels containing them as to deprive tissues on the distal side of their blood-supply. The Fellows, it was added, were immensely interested in the paper, and when it was finished they "laughed and cheered." Such demonstrations, if not stopped, were at any rate suspended during the reign of one very distinguished President. Dr. JAMES COPLAND, the author of the great Medical Dictionary, took the chair in 1853, and the first paper read after he did so was applauded by the audience. He instantly rose and condemned the practice in the strongest terms. The Fellows of the society, he said, were not actors but men of science, bound to listen to each other's opinions with respect, and they should be as incapable of the indecorum of applause as of the analogous indecorum of exhibiting displeasure. During the whole of Dr. COPLAND'S presidency the practice of applauding was abandoned. That of exhibiting displeasure at Berners-street commonly took the form of a gentle tapping with the heels, started at some single point, but certain to spread if it appealed to the general sympathies, and equally certain, before it had been long continued, to drown the voice or to overcome the resolution of the boldest or most persistent speaker.

The presidential chair of the society has naturally been a sort of blue ribbon of the profession, rendered every year more valuable by the eminence of those by whom it has been held, and always conferred alternately upon a physician and a surgeon. The President was not only an eminent practitioner but was usually selected from among men who had done good work in subordinate offices and whose known attachment to the society afforded security that they would be watchful guardians of its honour and of its interests. In this respect, indeed, they were all alike, but successive presidents have entertained very different ideas as to the share which they should take in the proceedings of the ordinary meetings. Some have considered it a duty to open every debate and to direct attention to what they conceived to be the chief questions raised by the paper which had been read. Others have contented themselves with taking the formal vote of thanks usually accorded to the author of the paper; and some have either intervened in the debates or kept silence as they might feel disposed. Dr. COPLAND usually spoke late and usually said that everything important either in the paper itself or in the remarks of the speakers would be found in such and such articles in his Dictionary—an assertion which was completely justified more often than might have been supposed. The great event of the presidential year was, of course, the address upon first taking the chair, which often included a retrospective glance at the work of the preceding session, brief obituary notices of deceased Fellows, and some kind of exhortation concerning the future—exhortation which sometimes conducted an unskilled orator into verbal snares or pitfalls from which escape was difficult or impossible. A president once expressed his hope that during the forthcoming session the working bees of the society would put their shoulders to the wheel, and his successor surpassed this effort by the hope that these same bees would unite with him to cull fruits in the stream of science. Such speeches were, of course, merely examples of what may happen when men even of conspicuous ability attempt work to which they are unaccustomed and from the requirements of which their minds have been diverted by other and more important pursuits. On the other hand, there were always Fellows of the society to whose periods it was a delight to listen, and the measured cadences of PAGET or of SAVORY would often be almost as powerful as their facts and arguments in giving character and distinction to a debate. As we think of those days the worthies of the past crowd upon the mental vision. ALDERSON, an exemplar of grace and courtesy; ADDISON, profuse of gesture, original, and didactic; BRODIE, already becoming in our day an infrequent visitor; GULL, tersely described as "a strenuous bird" and looked upon as a coming man at Guy's; ORMEROD, who then reported the proceedings of the society for THE LANCET and whose career of promise was cut short by cholera before Sebastopol; and ANDREW CLARK, steadily laying the foundations of his reputation in the pathological laboratory of the London Hospital. As there were strong men before AGAMEMNON, so there will be worthy successors of the heroes of the past, and the history of the society justifies it in looking forward to another century of usefulness and of success, if not in its present form then as an important constituent of a united Academy of Medicine. The attempt to federate has been vainly made on previous occasions but the present time seems undoubtedly to be propitious not only for its renewal but for carrying such a desirable project into accomplishment.

The Hygiene of Flat Life.

THE ultimate results of social changes can seldom be exactly predicted. The advocates of any social reform usually paint in vivid colours the Utopian conditions which will prevail if their schemes are carried out, but when the reforms so earnestly recommended have been introduced the looked-for benefits are often woefully less visible than had been prophesied; and not only so but new, unexpected, collateral results, by-products of the reform as we may call them, are found to have developed and the last state is in only too many cases but little improvement on the first. The conditions under which very many of the poorer classes live in all large towns are truly deplorable. The overcrowding is often extreme. Many will remember the late Mr. MONTAGU WILLIAMS'S anecdote illustrative of this. When he was the magistrate at the Whitechapel police-court a case came before him of a dispute ending in a free fight. After much questioning he found that in one room five families lived, one family in each corner and one in the centre, their respective domains being delimited by chalk marks. All went well until the family in the centre of the room decided to take in lodgers and this attempt at overcrowding was forcibly resented by the more particular dwellers in the corners. We do not know how far Mr. MONTAGU WILLIAMS was ready to vouch for the exact accuracy of his humorous story, but that such a tale should be considered a fair comment upon existing conditions goes far to show that in many districts of London the overcrowding is intense. To remedy this evil the energies of philanthropists and municipal bodies have been directed. Overcrowded quarters have been cleared and in place of ill-designed and ill-built houses lofty structures have been erected according to the latest teachings of hygiene.

The dwellers in these sanitary buildings are seldom the inhabitants of the old unwholesome tenement houses which have been swept away. The appreciation of these new "dwellings" is sometimes so great that the owners of them have the power of selecting amongst the applicants those whom they consider to be the most suitable, and then it comes to pass that the new tenants belong as a rule to a rather higher class than those who have been displaced. We do not wish for one moment to minimise or to detract from the benefits resulting from the erection of workmen's dwellings. We are sure that many hard-working people are able to obtain rooms with many hygienic appliances and fittings at a weekly rent lower than they would have had to pay if these "improvements" had not been carried out. So far so good, but there are some by-results of this hygienic building which were doubtless unintended by the well-meaning philanthropists who promoted their establishment but which are of sufficient economic importance not to be ignored. In order that the expense of the rooms of these model dwellings should not be excessive the rooms are made very small and as low in height as the average size of the people will admit, so that the cubic air space per inhabitant is by no means so great as we might expect from the hygienic protestations of the promoters. Not long ago the QUEEN after inspecting some model dwellings pointed out the need for cupboards, but one of the inhabitants remarked on hearing of this suggestion, "We've got the cupboards already, what we really want are rooms." When these buildings are erected by money bequeathed for the purpose, and when their rents are not expected to yield a dividend the chief objection to be urged against them is that, according to an interesting economic law, they tend to lower wages, though it has also to be remembered that they are not inhabited by the class for whom they were primarily intended. When, however, these model dwellings are erected by municipal bodies the case is altered, as for the most part they do not repay in rent the cost of building, so that the balance has to fall on the rates. This is one cause, amongst many others, of the recent rise in rates in London and other large towns. Now every increase in rates has a very direct effect in increasing the expense of living, for no personal economy on the part of a householder can affect the amount of rates which he has to pay. A natural consequence of this increase in rates has been the extension of the numbers of those who live in flats. We do not suggest that the increase in the rates is the only cause, or even the chief cause, but it certainly is a cause and not the least powerful cause, in causing the present migration of Londoners of all classes into flats. Now in flats we find a massing together of large numbers of people in circumstances that are often much open to criticism, so that one result of the efforts of municipalities to improve the hygienic conditions under which some of the poorer inhabitants live has been to deteriorate the hygienic conditions of some of those who are better off. The view that flats are not so hygienic as ordinary dwelling-houses is very generally accepted, but at a recent discussion at the Royal Sanitary Institute on the hygiene of flat life opinions were somewhat divided. The late Dr. FARR used to say that the mere density of the population increased the mortality but the statistics based on the returns at present available do not support this view. These statistics, however, are merely mortality statistics and give us no indication of the amount of sickness not immediately leading to death. To take an instance, there is a widespread belief amongst those who are qualified to judge that for servants flat life is especially unwholesome, but this harmful effect would not show itself in any mortality statistics. If we may judge from death returns servants on flats never die. In a flat there is no accommodation for a sick servant. Therefore, though in a flat a servant may fall ill or be permanently damaged in health by her stay there, yet we shall see no sign of it in the returns of the Registrar-General

The main hygienic defect of the flats is the absence of provision for through ventilation. The great price of the land on which flats are built requires that the buildings shall be high and closely packed. Thus it follows that many of the rooms look upon inclosed air "wells," where a column of air remains almost stagnant from day to day. The staircases and corridors are also equally guiltless of circulating air. Attempts have been made by the architects in some cases to provide for thorough perflation of air by openings at the base of the air wells, but in several instances it has been found that these air inlets have been bricked up or glazed because someone has complained of the draught. The difficulty of providing for through ventilation is the supreme difficulty of the hygiene of flats and it requires to be taken into careful consideration. In many ways the modern flat is a better constructed and more conveniently planned dwelling than the house, but the conditions of its erection compel, or well-nigh compel, stuffiness. It is impossible to prevent the increase in the number of flats. In all large cities flats are a necessity from the appreciation of the ground value of the land. In Rome, the most ancient of the present-day large cities, flats have existed to a large extent for centuries and if the idea is well founded that Rome had in the time of the Emperors a population of over 1,000,000 the existence of flats in the Eternal City may be considered as proved for that epoch, and if so they have existed there for nearly 2000 years. Flats being inevitable, it would be well to insist on the provision of through ventilation, as the most important factor in the improvement of their hygiene.

◆

The Session of the General Medical Council.

THE eighty-first session of the General Council of Medical Education and Registration began on Tuesday last. In his opening speech Dr. MACALISTER, the new President, outlined a businesslike programme of modest dimensions, a fact which is of good omen. The scope of the duties of the Council is so large, and so much of its work is associated with public interests of the widest sort, that one of the principal difficulties before it is to decide what are the subjects that require special attention. There are but two sessions in the year, although on one or two occasions a special session has been held, and the cost of each is so considerable that it is out of the question that the Council should meet more frequently. Moreover, even if money were of no consideration, it must be remembered that the members of the Council are for the most part busy men whose time is charged and surcharged with public and private duties, so that in many cases they sit at the Council board only with considerable sacrifice of valuable time. Two sessions, however, each usually amounting to less than a week, hardly suffice for dealing with all the vast number of questions that may arise. The relations between the medical profession and the public are regulated entirely by the Council, the maintenance of an accurate Register and the purification of that Register from wrong persons is also its duty, while, perhaps most important of all, the standardisation of medical education is also in its hands. When we remember the vast field that such various functions must offer for discussion we see that a fortnight (or less) in the year is not an excessive amount of time for the public deliberations of the Council, even though much of the real work is done by committees, by inspectors and visitors, and by the President in the intervals between the sessions. A short programme pointing rather to action than to oratory is consequently welcomed by the medical profession, who are also beginning to take note that their interests are not best served by the members who make the most or the longest speeches.

The President was able to make a very satisfactory statement with regard to the funds of the Council. At the end of 1903 the total deficit of the Council was a little over £2000 and at the end of 1904 it is only a little over £200, this greatly improved position being attributable not to any increase of ordinary income but to greater economy of expenditure. Whether the pecuniary situation can be improved until the point of equilibrium is reached, and whether such equilibrium, if reached, can be maintained, seem to us rather doubtful, but the results of economy and orderly administration are very marked, and it must be a great relief to the members of the Council, and to all those of the medical profession who take an interest in the work of their disciplinary body, to feel that for a time at any rate the cloud of bankruptcy appears to be dispelled. It is more than an undignified thing that the General Medical Council should be out at elbows. It is a dangerous position of affairs, because it is inevitable that the policy of the Council should to a certain extent be guided by the money at its disposal. Take, for example, the registration of the medical student. Two sessions ago the General Medical Council decided to promote a Bill in Parliament for the compulsory registration of all medical students upon payment of a small fee. Doubtless the Council was swayed in its decision by the belief that, as it had under its charge the medical education of the country, it ought to have official control over the educational career of every student from the time that he becomes a student to the time when he obtains the right to admission upon the professional roll. But, in addition to the very natural feeling that it was a fit thing that the Council should insist upon registering all students at the beginning of their careers, the Council was also influenced by the knowledge that the institution of a small fee for registration would result in raising an annual sum of money sufficient to turn the vexatious and recurring deficit into a genuine though insignificant surplus. Certain of the educational bodies proved, however, to be strongly opposed to the Bill. They considered it an infringement upon their rights with regard to their students, and when the Council found that the projected measure bade fair to be unpopular it was dropped. Many who are interested in medical politics regret that the Council did not feel strong enough to persevere in its intention, but undoubtedly the Council would have enjoyed greater advantage in opposing the resistance to its views had it been *inspired solely by a wish to consolidate the scheme of* medical education and not at all by a hope of raising the wind—if the colloquialism may be pardoned us.

An important question which the General Medical Council will soon assuredly have to look into is the disorder that exists with respect to medical titles, and the matter was brought forcibly to the attention of the Council on the first day of the present session. It is not so very long ago since a barrister, who ought to have known better, alluded to a Licentiate of the Society of Apothecaries of London in open court as "possessing the lowest medical degree." The barrister in question, not, of course, either a very well-informed or a very civil person, misled by the title of "licensed apothecary," seems to have thought that the medical witness was not a physician or a surgeon, although, as is well known to all our readers, the Licentiates of the two Societies of Apothecaries are distinctly stated at the beginning of the Medical Act of 1886 to be qualified to practise medicine, surgery, and midwifery. A large number (767) of Licentiates of the Apothecaries' Society of London, feeling that some error as to their position may be common, petitioned the General Medical Council at the opening of the session to have their official designation changed from "Licentiate of the Society of Apothecaries of London" to "Licentiate in Medicine, Surgery, and Midwifery of the Society of Apothecaries of London," and their petition was sympathetically received by the Council as a whole. And sympathy is all that the petitioners will get for the present and all that they can expect, for an Act of Parliament would be required to bring about the change of title which is desired. But the subject of medical titles which has thus been introduced to the notice of the Council is one that is bound to ask for further attention. The anomaly by which a man is called an apothecary when he is, as a matter of fact, qualified to practise medicine, surgery, and midwifery is only one of numerous irregularities in medical titles. Why is the main body of the Royal College of Surgeons of England called differently from the main body of the Royal College of Surgeons of Edinburgh or in Ireland? Why do some bodies object to their Licentiates using the title "doctor" *while others permit it? The public is naturally misled into* thinking that a "Member" is better than a Licentiate, or that a "Licentiate" who styles himself without apprehension "doctor" is superior to a Licentiate who does not use the popular title. These ideas of the public reflect unfairly upon many medical men, and the right of all registered medical practitioners to use as a matter of course the designation of "doctor," by which the public always address the practitioner, will be pressed hardly in the near future.

Annotations.

"Ne quid nimis."

MEDICAL CERTIFICATES IN RESPECT OF SCHOOL ATTENDANCE.

A CORRESPONDENT has asked us whether it is consistent with ethical conduct for a medical man to accept an appointment from the education committee of a county council under which he will have to visit and to examine children the patients of other practitioners and to give medical certificates in respect of their fitness or otherwise to attend school. The question is not quite a simple one, though the answer is that, as a rule, such appointments must be very unfortunate. Take, for example, the position in the county of Kent. In 1904 the new education committee of the Kent county council circularised the medical profession of the county asking them to undertake to visit, to examine, and to certify children for school board purposes for a fee of 1s. per head. The proposal was naturally not received with much enthusiasm. In the Sevenoaks division of the British Medical Association, for example, two men out of 20 or so were found ready to accept such an offer, but representations were made to them which induced them to withdraw their acquiescence. A formal letter of protest at the offer of such fees was then sent to the county council committee and the matter was for the time being dropped Our correspondent does not say what fees have been offered in the instance to which he alludes, but if they were such fees as were offered last autumn by the Kent county council we think that they should not be accepted The question of fees is not the only one at stake A dangerous source of professional friction will be created if these semi official posts should be filled by medical men simply to save the pocket of public bodies The Kent county council sought to get its work done at low fees and failed Other bodies, and for aught we know the Kent county council again, may now try by offering the work to one practitioner in each district to get out of paying reasonable fees to the medical profession as a whole, and medical men should not assist such tactics Awkwardness must be produced when one medical man is placed in a semi official position so that it may be his duty to interfere with the patients of his *confreres* In cases of summons for non attendance, if the usual medical adviser, probably inspired by a more intimate knowledge of the patient, did not agree with the semi official diagnosis, the parent would obtain medical evidence supporting his view against the view of the school board, and most undesirable conflicts of expert testimony would ensue There is no need for educational authorities to create a special appointment for a medical man to sign certificates All that is wanted is that the medical man in attendance upon the sick children should be remunerated for giving certificates A question asked in the House of Commons by Mr Rowland Hunt on Monday last showed that the Board of Education did not consider a medical certificate to be the only valid defence for non attendance at school, but surely there are not many magistrates who, save in exceptional circumstances, would accept any other certificate

SPRING CLEANING AND COLD WEATHER.

A cold "snap" in May is particularly unfortunate in regard to household affairs, since most industrious housewives decide to have the "spring cleaning" process finished before the dawn of "the merrie month" and there is not a more decisive ukase in domestic affairs than that which forbids the reversion to coal fires after spring cleaning is done It may be presumed that no such prohibition would obtain in the house in which electricity or gas is used for heating purposes The considerable, if not actually harmful, inconvenience which the inmates of a house suffer in these circumstances is, in fact, tolerated because the use of coal fires would undo the work of the spring cleaning process They are to sit shivering in the rooms because the lighting of the fire would bring in its train a recrudescence of the very kind of dirt which vernal labour has taken so much pains to remove We see here a powerful argument in favour of the abolition of the coal fire altogether and the adoption of a gas fire or electric heater in its place We also have no hesitation in declaring that so long as the English climate exhibits sundry ficklenesses of the very disagreeable kind which we have just recently experienced the cold having been as intense as anything experienced during the winter, the present system of spring cleaning, or cleaning in spring, is based on a very inconvenient and dangerous postulate If at any rate spring cleaning means that the maintenance of a comfortable warmth in the house is precluded, that the household must shiver because cold weather happens to prevail on the conclusion of the process, then surely the institution deserves to be abolished as contrary to common sense and as opposed to the requirements of health The slavish adherence of the housewife to principles of cleanliness is excellent in its way but over zeal in this direction might well be fraught with serious issues to the health of the family Either the rule about fires should be relaxed or else "spring cleaning" should be made to give way to "summer cleaning" or postponed until a more convenient and congenial season when cold "snaps' are far less likely to occur

THE ROYAL INSTITUTE OF PUBLIC HEALTH.

The preliminary programme of the forthcoming congress of the Royal Institute of Public Health, which is to be held in London from July 19th to 25th, has just been issued The congress will be held in King's College and at the Polytechnic, Regent street, London, W In the section of Preventive Medicine, which will be presided over by Sir James Crichton Browne, there will be discussions on the Medical Inspection of School Children, the Teaching of School Hygiene the Waste of Infant Life, and Municipal Milk Depots, while in the section of Bacteriology and Chemistry, the President of which is Professor R T Hewlett, the Bacteriological Examination of Milk, Water, and Sewage will be discussed Professor John McFadyean is the President of the Section of Veterinary Hygiene, Colonel A Crombie, I M S, of the Section of Tropical Medicine, and Lieutenant Colonel R H Firth, R A M C, of the Section of Naval and Military Hygiene Special arrangements have been made to visit various institutions under the control of the Metropolitan Asylums Board and there will be an exhibition of sanitary, and educational appliances The social arrangements include various excursions to Henley, Windsor, and Hatfield, visits to places of interest in the metropolis, such as the Mint, the Bank of England, and Greenwich Observatory, and a garden party The subscription for membership of the congress is £1 1s and for ladies accompanying members or delegates 10s 6d The President of the congress is the Marquis of Londonderry and the honorary secretary is Mr James Cantlie, from whom further information can be obtained at the Royal Institute of Public Health, Russell square London, W C

CORONERS INQUESTS IN LIVERPOOL

The official relations of coroners to practitioners of medicine are not in all cases characterised by the courtesy and good feeling that should exist among members of the learned professions all readers of The Lancet are well aware of this In particular, as regards that important function which has for its object the discovery of the cause of death by violence, or in suspicious circumstances, it is unfortunately true that certain coroners occasionally assume an attitude towards medical witnesses which is but ill calculated to accomplish the object in view A case has recently occurred in Liverpool where a man died in a fit some considerable time after receiving an injury The medical man who saw him, believing that the injury had occurred some two years before death, did not mention the injury in his certificate, but later, finding out that the injury had been received within a year of the death, he made a communication to the widow which led to an inquest At the inquest the medical man said that he had followed the usual belief that there was no necessity to mention an injury in the death certificate if the patient had survived that injury for a year unless the connexion between the injury and the ultimate death were obvious At this point a wrangle is reported to have occurred in which the coroner, the medical man, and two solicitors took part, and which, as might have been foreseen, was not calculated to enhance either the dignity or the efficiency of the coroner's office The coroner appears by the newspaper reports to have said that the medical man in giving his view, which to us appears a perfectly reasonable one, "was talking nonsense," adding that "according to the rules of the Registrar-General if an injury happened ten years before death the fact should be shown in the certificate." The coroner is reported to have made this statement in his magisterial capacity and it was incumbent upon him to make sure of the accuracy of his assertion. As far as we know the only official communication hitherto addressed to medical men from Somerset House which bears on the matter consists of a printed circular, not of rules laid down, but of suggestions courteously offered to practitioners of medicine as to the manner in which causes of death should be returned for entry in the Registrar-General's reports. Having read a copy of that document we fail to find there any rule such as that alluded to by the coroner. We trust therefore that he will take an early opportunity of informing the medical profession of Liverpool on what authority his statement was made as to rules laid down by the Registrar-General. But even if that officer had made such a rule we have yet to learn what authority the Registrar-General possesses to regulate the conduct of medical practitioners beyond requiring them in all cases to fulfil the statutory obligation to certify the cause of death of their patients. After all, the medical man is, and always must be, the judge of the cause of death. He is not a detective officer, and if, amid the manifold worries of medical practice, he occasionally omits to record in his certificate a mere hearsay statement which a coroner may desire to know but which in his own judgment is irrelevant to the case before him it would manifestly be unjust to censure him for the omission. In the present case we cannot see that the coroner had any just ground for his strictures. Shortly after the death of his patient the medical man apparently filled up the certificate "to the best of his knowledge and belief." His *bona fides* is evident from the fact that immediately on becoming aware that an injury had preceded the fatal fit by a less interval of time than had been represented to him on taking charge of the case he brought the matter under the coroner's notice. The medical man's evidence ought to have made it quite clear to the coroner that no irregularity had been committed and that the course of justice had not been endangered in any way. Possibly he missed the significance of the evidence by not being sufficiently well up in ordinary scientific knowledge, but this does not give him the right to tell the medical man that he was talking nonsense.

OZONE IN PUBLIC LAVATORIES.

THERE is no sweeter or more effectual deodoriser than ozone and yet how rarely is ozone employed for this purpose in practice. The peculiar and refreshing smell of ozone is infinitely preferable to the sickly smell of chlorine compounds and tar acids, although these smells may serve to give the public some confidence that where such smells prevail there must necessarily be no risk of infection. In many cases this confidence is undoubtedly misplaced since tar oils in particular which smell strongly have practically little or no germicidal action, whereas the true tar acids, such as carbolic acid and cresylic acid, have a comparatively feeble smell but are very active disinfectants. After all, the action of "chloride of lime" as a disinfectant depends chiefly upon its decomposition by the carbonic acid of the air (which is not a very large quantity) into carbonate of lime and hypochlorous acid. The production of the effective disinfecting compound hypochlorous acid is therefore small, though of course it is steady. The smell of tar compounds, naphthalene tablets, or chlorine powders when coupled with that of the ammoniacal emanations of public lavatories is very offensive to most people. Far better, and certainly much more agreeable for the purpose, would be ozone, to which, moreover, ammoniacal gases readily yield. Ozonisers are so easily procured now and are so simple in construction and in action that it is a matter of considerable surprise that they are not more frequently applied for the purpose of sweetening air befouled with offensive smells. Nor does ozone merely mask a bad smell; in all probability it destroys it. Again, most public lavatories are provided with an installation of electricity for lighting purposes and it would be a very simple matter to utilise a fraction of the current for actuating a battery of small ozonisers. The suggestion, too, if adopted would spare the sewers from the possible corrosive action of certain disinfectant compounds and from blocking by insoluble powders and perfectly futile soap disinfectant tablets.

SUBACUTE PERFORATION OF THE STOMACH.

IN acute perforation of the stomach the gastric contents are extravasated into the general peritoneal cavity and general peritonitis is produced. But in certain cases of perforation the opening is very small and becomes plugged by omentum or by fibrin and only local peritonitis results. Cases of this form of perforation are not well recognised. In the *Boston Medical and Surgical Journal* of May 4th Dr. F. B. Lund has published an important paper on this condition which he terms "subacute perforation of the stomach." Under careful treatment the fibrinous adhesions may become organised into fibrous tissue and the ulcer may heal. On the other hand, the adhesions may be digested and the peritonitis may spread and after two or three days may develop rapidly and prove fatal in a few hours. Finally, a chronic abscess may form. The symptoms of subacute perforation of the stomach differ from those of acute perforation in being less intense and in not being followed by collapse or general peritonitis. In a patient, who may or may not have had symptoms of gastric ulcer, sharp stabbing abdominal pain, with or without vomiting, suddenly occurs and is followed by localised tenderness and rigidity. Under treatment the tenderness and rigidity pass off after several days. When the surgeon sees the patient the attack is generally subsiding and the question of diagnosis arises. The locality of the pain and tenderness do not give much aid. If the ulcer is situated on the anterior surface of the pylorus the peritonitis glues the latter to the liver. The pain and tenderness are so near the gall-bladder that it is impossible to exclude acute cholecystitis. The history of a previous attack of biliary colic or the character of the pain and its relation to meals may respectively point to gall-stones or to gastric ulcer. But the diagnosis can often be made only after operation. Dr. Lund relates the following three cases. A lad, aged 20 years, was admitted into hospital on Oct. 3rd, 1903. For about a year he had suffered occasionally from epigastric pain and for six months he had always had pain after meals. A week before admission while boxing he was struck in the right hypochondrium, where he had slight pain until the day before admission, when he was seized with violent griping pain in the epigastrium which spread all over the abdomen. He vomited after taking warm drinks and had a chill lasting an hour. He walked to the hospital. The temperature was 100·3° F. and the pulse was 60 and the skin was slightly yellow. The abdomen showed no distension; there were slight general rigidity and marked rigidity and tenderness in the region of the gall-bladder. No mass could be felt. The leucocytes were 16,000. Under rest in bed the tenderness and rigidity disappeared. Gall-stones were diagnosed. On Oct. 7th an incision was made through the upper part of the right rectus muscle and the gall-bladder was found to be normal. On opening the peritoneum an excessive quantity of clear dark peritoneal fluid was found. The appendix, which was chronically inflamed and adherent to the outer side of the colon, was removed. But it was thought that the fluid in the peritoneum was not explained. Further examination showed that the pylorus was connected with the under surface of the liver by fresh adhesions. Posterior gastro-enterostomy by the method of Moynihan was performed. The patient regained perfect health and lost all gastric symptoms. In the second case a man, aged 40 years, was seen in consultation one night. For years he had suffered from indigestion and for several months his stomach had been washed out but he did not improve. At 1 P.M. on the day on which he was seen he got out of bed and went to the door to look out and was seized with severe abdominal pain. He vomited and crawled back to bed. At 3 P.M. he was seen by a practitioner who found a pulse of 90 and a temperature of 101°F., with board-like rigidity and general abdominal tenderness, which was especially marked in the epigastrium. There were no signs of shock. A quarter of a grain of morphine was given. At 9 P.M. he had improved, the spasm was a little less, and he seemed more comfortable. At 11 P.M., when Dr. Lund saw him, he was pale and anæmic but did not show the peritoneal facies or marked shock. There were distinct spasm and tenderness in the epigastrium which shaded off into the other regions of the abdomen. The tongue was moist, the pulse was 90, the temperature was 101·4°, and the abdomen was retracted. As the vomiting had not been repeated, the spasm had decreased somewhat, the pulse was not increasing, and the patient was more comfortable, it was thought that a perforation had occurred but was walled off from the general peritoneal cavity. Operation was therefore deferred until the following morning when the patient's condition was about the same. The pylorus was found connected by fresh adhesions to the under surface of the liver. Fresh flakes of fibrin extended across the greater part of the anterior surface of the stomach, especially along the lesser curvature. There was an excess of serum in the peritoneal cavity. Posterior gastro-enterostomy was performed. Solid food was taken on the fifth day and after two weeks the patient was eating more than he had done for years and without any distress. Three months later he had gained much weight and was in excellent condition. In the third case the patient was a man, aged 50 years, who was admitted to hospital on June 3rd, 1903. He had always been constipated, his bowels acting only once or twice a week. For five weeks he had had epigastric pain and for three days it had been severe. The abdomen was distended and there were dulness, tenderness, and spasm in the left hypochondrium. An enema brought away large masses of scybala and he became more comfortable. On the 10th there was still a tender mass in the left hypochondrium and an incision was made over it. The stomach was found adherent to the anterior abdominal wall and much thickened. On separating it a perforation about a quarter of an inch in diameter was found near the cardia. After walling off the ulcer was infolded and posterior gastro-enterostomy was performed. Recovery followed. These cases show well that the location of the pain and tenderness depends on the position of the ulcer. Dr. Lund recommends that in such cases posterior gastro-enterostomy should be performed without, if possible, breaking up the protective adhesions.

THE OPTICAL CONVENTION.

THE Optical Convention for 1905 will be held on May 30th in the Northampton Institute, Clerkenwell, E.C., under the presidency of Dr. R. T. Glazebrook, F.R.S., and among the vice-presidents are Lord Kelvin, Lord Rayleigh, the Earl of Rosse, Sir Howard Grubb, and the Astronomer-Royal. The aims of the Convention are to increase the interest taken in optical science in this country, to promote an improvement in technical education in optical matters, and to aid the development of the British optical industry. The programme of the Convention includes meetings for papers and discussions, which will be subsequently published in a volume, and an exhibition of optical and scientific instruments of British manufacture, with a catalogue which is intended to serve as a work of reference illustrating the productions of opticians in this country. Among the papers and the discussions are promised contributions by Lord Rayleigh on the Polishing of Glass Surfaces, by Professor Poynting on the Parallel Plate Micrometer, and by Professor Schuster on Spectroscopic Optics. The subjects dealt with include the design of optical instruments, the measurement of aberrations, diffraction in optical instruments, and various questions connected with photography, photometry, ophthalmometry, and the like. The Earl of Rosse, Lord Blythswood, and Sir William Abney are among those who have promised to preside at the sectional meetings.

FRESH AIR AND THE BURGLAR.

THE principles of living as much as possible in the fresh air should, of course, extend to the bedroom, although there is a common but erroneous impression that night air is unsuitable, if not dangerous, for respiration during sleep. As a matter of fact, night air is generally purer than the air by day, since it is freer from suspended particles of dust—bacteriological entities which arise from the disturbance of the day's traffic. Night air is, moreover, comparatively free from the pollutions of the chimney but it is naturally cooler than in the daytime and often deposits moisture, especially on an unclouded night when the radiation of the earth proceeds rapidly. Such moisture is, however, deposited on rapidly cooling surfaces and is not likely to be formed in the bedroom. The sleeper is, as a rule, adequately protected against changes of temperature by the powerful non-conducting property of the bedclothes and, of course, it is desirable that no part of the body should be directly exposed to a cold draught. There can be no doubt that the inspiration of fresh pure air during sleep considerably promotes the well-being of the individual and gives him a much stronger sense of recuperation than when a supply of fresh air is excluded. Oxidation and the destruction of toxic products are encouraged in the former case, while in the latter the impure products of respiration may be breathed again and again. Many persons who are professed followers of the doctrine of fresh air are precluded from carrying their convictions on this point into practice at night because they fear that leaving windows open will give an easy opportunity to the burglar. And in many houses, especially in the suburbs and country, such is undoubtedly the case. It is a pity that such fears tend to prevent the healthy policy of sleeping in fresh air from being carried out but there should be no difficulty in overcoming them. The fact that the majority of persons sleep during a third part of their lives enhances the desirability of recognising the importance of the admission of fresh air into bedrooms.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, HAMPSTEAD AND NORTHWOOD.

A COURSE of post-graduate lectures and demonstrations, free to members of the profession and medical students, will be held at the central out-patient department, 7, Fitzroy-square, London, W., on Thursdays, at 5 P.M. Dr. George A. Heron delivered the introductory address on May 18th and on May 25th Dr. J. Edward Squire lectured on Difficulties in the Diagnosis of Chest Affections. The subsequent lectures and subjects will be as follows: June 1st, Dr. George F. Johnston on the Pathology and Treatment of Asthma;

June 8th, Dr. F. Parkes Weber on Pneumothorax in Tuberculous Subjects; June 15th, Dr. T. N. Kelynack on Cases of Arrested and Advancing Pulmonary Tuberculosis; June 22nd, Dr. T. D. Lister on Pre-Tuberculous Affections in Early Life; June 29th, Dr. F. W. Price on Aortic Stenosis; July 6th, Mr. James Berry on Foreign Bodies in the Air-passages; July 13th, Mr. Harold S. Barwell on the Diagnosis of Tuberculous Laryngitis in its Early Stage; and July 20th, Dr. Herbert J. Scharlieb on Some Post-Anæsthetic Complications.

THE TRAFFIC IN OLD HORSES.

WE have from time to time[1] protested against the cruelty involved in shipping old broken-down or diseased horses to ports abroad and a peculiarly scandalous case came before Mr. Mead at the Thames police-court on May 16th. The accused was a man named John Ellett. The horse was seen by Inspector W. Rogers of the Royal Society for Prevention of Cruelty to Animals. It was in a float and was apparently suffering great pain. Mr. Ellett on being questioned said that he had sent the horse and that he knew "the feet were a bit rotten." He continued: "I bought it to sell to White for shipment abroad. They fetch a better price there." Mr. Mead, in sentencing the prisoner to one month's imprisonment, said that the whole traffic was a most discreditable one. We quite agree with Mr. Mead; the traffic is more than discreditable, it is disgusting. These wretched animals are mostly shipped to Rotterdam, where their flesh is used as food, and we suspect in some instances returns to this country in the form of sausages or "delicacies" of various kinds. In our opinion the traffic should be made illegal. A little time ago something was done to make it somewhat less revolting by means of a Board of Agriculture order but without doubt it should be stopped altogether.

THE DURATION OF THE INCUBATION PERIOD OF TETANUS: A MEDICO-LEGAL QUESTION.

IN the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of April 30th a case is reported which is of considerable importance both from the pathological and the medico-legal standpoints. On April 17th, 1902, a navvy in the employment of a railway company and a comrade were lifting a rail with a crowbar when the crowbar slipped and his little finger was crushed between the crowbar and the rail. Suppuration followed and after being incapacitated for 17 days the man resumed work. About the end of June he had a boil on the knee which prevented him from working for a fortnight. Towards the end of August he manifested symptoms of tetanus and he died on Sept. 17th. His widow brought an action against the company, claiming that the injury to the finger was the cause of the tetanus. The question arose, Could the incubation period of the disease be so long as four and a half months and the tetanus have been due to the injury? As is the fashion in French courts, the judge referred the question to a committee of experts consisting of Professor Ferré, Professor Sabrazès, and Dr. Faguet. They consulted both French and foreign works on tetanus. The ordinary incubation period was given as from five to 15 days, especially by recent writers. But some writers stated that the incubation period might be as long as from 20 to 30 days, several months, and in one case (mentioned by Heineke) even two years. However, these long incubation periods were given at a time when the pathogenesis of the disease was not well known. Thus, in the case in which the period was alleged to be two years the disease was attributed to a bullet wound, but the fact was overlooked that it might have been due to a much later injury, as the patient was in the habit of giving himself injections of morphine. Turning to experiments on animals M. Vaillard and M. Rouget reported in the *Annales de l'Institut Pasteur*, 1892, a case which, however, was unique in their experience. In order to ascertain whether a guinea-pig born of a mother vaccinated against tetanus was immune they injected fluid containing the spores of tetanus. After an incubation period of three and a half months symptoms of tetanus manifested themselves and the animal died. The experts reported to the court that in the present condition of science it had not been shown that the incubation period of tetanus in man could be as long as four and a half months and that a relation of cause and effect had not been shown to exist between the injury to the finger and the attack of tetanus. Judgment was given against the plaintiff.

BRITISH DENTAL ASSOCIATION.

THE twenty-fifth annual meeting of the British Dental Association was held at Southport on May 20th, 22nd, and 23rd. The report of the representative board showed that the membership of the association continues to increase, the number now standing at about 1400. Reference was also made in the report to the appointment by the Admiralty of three dentists to the navy and regret was expressed that the army authorities had not been permitted to increase their dental staff, the blame apparently resting with the Treasury. The address of the new President, Mr. T. Gaddes, was full of interest. He drew attention to the great increase in the number of persons practising dentistry unregistered and he gives the following figures: "Within the area of the North Midland branch there were in 1899 125 unregistered persons practising dentistry. In five years (1904) the number had increased to 303. In Leeds alone there were 16 in 1899 and over 40 in 1904." This condition is, as he truly states, due to "the most regrettable state of the law as to practice." With regard to dental education he expresses the hope that no impediment will be placed in the way of students for the dental qualification and considers that the present curriculum must not be extended or the examination made more severe. The need of efficient dental services for the poor would, he considers, be best met by the establishment throughout the country of provident dental aid associations, guilds, or dispensaries. A considerable portion of the address was devoted to the prevalence of caries of the teeth and its results and the teaching in the elementary schools of oral hygiene was advocated.

"CANCER BODIES" AND NORMAL REPRODUCTIVE TISSUE.

WHEN, in a communication to the Royal Society in 1903, Professor J. B. Farmer, Mr. J. E. S. Moore, and Mr. C. E. Walker described the resemblances which they had discovered between normal reproductive tissue and the tissue of malignant growths their observations were confined to the peculiar forms of nuclear division common to these two tissues. The special points of resemblance recorded were subsequently confirmed last year in the laboratories of the Imperial Cancer Research Fund by Dr. E. F. Bashford and his fellow workers. In a communication to the Royal Society on May 11th of the present year Professor Farmer and his two collaborators describe a striking resemblance, extending to minute points of detail, existing between "Plimmer's bodies," which have been regarded as cancerous products, and certain normal constituents of the cells directly concerned in spermatogenesis. As is well known to those familiar with the literature of the subject, "cancer bodies" have frequently been observed by different investigators and they have been interpreted as representing various parasitic organisms The writers of the paper, the text of which will be found in another column, bring forward weighty evidence against such a view They maintain that the bodies in question are strictly analogous to, or identical with, those occurring in the normal course of spermatogenesis The appearance of sporulation which has favoured the hypothesis as to the parasitic nature of the bodies is shown to exist as a definite stage in the protoplasmic structure of the normal reproductive tissues in which the complete series of events is clear and is susceptible of no misinterpretation Whilst the writers regard the structures in question, whether occurring in malignant or in reproductive cells, as identical, they are careful to point out that they do not on this account extend this identity to cover the nature of the cells themselves They still hold, as they have always maintained, that there exists a similarity between reproductive and malignant tissues and they adhere to the term "gametoid" as expressing the resemblance, whilst also emphasising the differences The new discovery presses the similarity still closer, but the writers are inclined to see in it evidence of the maintenance in the one case of a primitive type and in the other case a reversion to such a type

---

[1] THE LANCET, Dec. 3rd, 1898 (p. 1492); Feb. 16th (p. 495); April 13th (p. 1095) and 27th (p. 1219), 1901; and April 11th, 1903 (p. 1045).

PUBLIC HEALTH IN HONG-KONG

IN *the introductory paragraph of his report on the* health of Hong Kong during 1904 Dr Francis W Clark, the medical officer of health, mentions that the district under the jurisdiction of the sanitary board has an area of 29 square miles, a non Chinese population of 18,900, and a Chinese population of 342 306, making a total population of 361,206 Of the Chinese population 72 9 per cent are males The corrected general birth rate was 4 9 per 1000, among the Chinese alone it was 4 4 per 1000, and among the non Chinese community it was 13 9 per 1000 The death rate among the Chinese community was 17 18 per 1000 and among the non Chinese resident civil population it was 17 58 per 1000 Only three deaths from plague occurred among the non Chinese community, all of them being Indians The total number of deaths among the Chinese from malarial fever was 289, while among the non Chinese it was 12 The total number of cases of infectious disease reported by registered medical practitioners during the year was 758, of which 510 were plague 129 were enteric fever, 41 were cholera, and 64 were small pox Dr Clark says that owing to the Chinese custom of manuring market gardens with human fæces it is dangerous to eat raw salads in the colony unless grown in a private garden under the immediate care of a European The highest shade temperature recorded was 91 1° F on June 26th The total rainfall was 80 41 inches and the wettest month was August with 27 64 inches The greatest amount of rain which fell on any one day was 11 13 inches on August 25th

SYPHILIS AND THE SPIROCHÆTE PALLIDA

AT the meeting of the Paris Academy of Medicine held on May 16th M Metchnikoff read an important communication He reminded his audience that in 1902 M Bordet and M Gengou had found a spirochæte in syphilitic chancres and also in many cases in mucous plaques of the throat But as similar micro organisms are known to exist in normal throats M Bordet and M Gengou did not feel justified in insisting on the specificity of this germ In order to control the results obtained quite recently by M Schaudinn and M Hoffmann upon the pathogenic agent of syphilis M Metchnikoff undertook some bacteriological researches into syphilitic lesions occurring both in human beings and as the result of experiment In four out of six syphilitic monkeys he found the spirochæte which was distributed indifferently in chancres, mucous plaques, and in serous exudation In human beings the germ was also found in four cases out of six, both in chancres and in early papules M Metchnikoff considers that the search for the spirochæte, which is not found in other cutaneous diseases, will serve as a diagnostic point in syphilis The germ is difficult to cultivate but M Metchnikoff hopes to arrive at positive results and to be able to obtain an antisyphilitic "vaccine" Syphilis would therefore appear to be a chronic spirillosis due to the spirochæte pallida

THE medical officer of health of the Cape Colony states that for the week ending April 22nd the condition of the colony as regards plague was as follows At East London six cases of plague and at King William s Town two cases of plague were discovered during the week, all the patients being natives Plague infected rodents were found at Port Elizabeth, Uitenhage, and East London, and at the latter place two plague infected cats were also found In the other districts of the colony no case of plague in man or other animal was found In Brisbane Queensland, the last case of plague was reported on April 1st and the last plague infected rodent was found on April 6th During the week ending April 22nd one case remained under treatment At Hong Kong during the week ending May 20th there were 20 cases of plague with 18 deaths

IN connexion with the Festival Dinner in aid of the funds of the National Hospital for the Relief and Cure of the Paralysed and Epileptic at the Whitehall Rooms on June 15th, at which Lord Strathcona will preside a collection has been made amongst the members of the Stock Exchange amounting to £908 9*s* Already a sum of over *£2000 has been received in response to Lord* Strathcona s appeal and it is hoped that a large part of the £5000 necessary to obviate closing wards will be forthcoming

THE Romanes lecture for 1905 will be delivered by Professor Ray Lankester, M A, F R S, Honorary Fellow of Exeter College director of the Natural History Museum South Kensington, in the Sheldonian Theatre, Oxford, on Wednesday June 14th at 2 30 P M The subject of the lecture will be Man and Nature

THE annual extra metropolitan gathering of the Otological Society of the United Kingdom will be held on June 3rd at Manchester By permission of the Vice Chancellor the members will meet in the pathological theatre of the Victoria University

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS

A MORNING AT HÔTEL-DIEU

BY EDMUND OWEN, F R C S ENG,
SURGEON TO THE FRENCH HOSPITAL, LONDON

THOUGH to my certain knowledge Dr Lucas Championnière was heavily engaged in dispensing hospitality till late into the night of May 12th, he still held to his appointment for 9 30 at Hôtel Dieu on the 13th And, sure enough, as Notre Dame marked the half hour the illustrious French surgeon arrived "Come first into the wards," said he "I have got some bone and some joint-cases which I am sure will interest you"

The *first* case was that of a young man who, till a few years ago had been a complete cripple on account of extreme double talipes equino varus of congenital origin He practically had never walked before he came under the care of Dr Lucas Championnière The plaster casts of his two feet showed how serious the deformity had been The operation performed on him had consisted in the removal of all the tarsal bones except the lower part of the os calcis, and it had enabled the feet to come straight and square. Though small and short, they were extremely useful, and the man took great delight in showing them off by squatting down on them and so flexing them to less than a right angle. The result of this operation left little to be desired, and the surgeon said that it had been secured by the great freedom with which the tarsus had been cut away. He remarked that he had once been taken to task by some anatomical friends when he had made the statement that the chief use of the tarsal bones was certainly not for the purposes of progression. This operation was Lund's method carried to an excess. Lund might, indeed he would, have removed the astragalus in each of the feet under consideration, but he would not have gone on to take away with it the adjacent part of the calcaneum and the five remaining bones of the tarsus. Skiagrams showed the bases of the metatarsal bones lying at the front of the os calcis and close beneath the end of the tibia.

Shortly afterwards the surgeon demonstrated the case of a young woman who had had what he called *une jambe à la Polichinelle*—that is to say, a lower limb left useless and deformed with infantile paralysis. First he had excised the knee and thus obtained solid synostosis of the tibia with the femur. Then he had brought the foot into a sound and useful position by removing the chief part of the tarsus as just described. Although this patient was still in bed the case seemed full of promise. Finding how useful a foot could be obtained after a radical tarsectomy, Dr. Lucas-Championnière had adopted that operation in the treatment of several bad cases of flat-foot, but he had been disappointed with it and had now abandoned it in dealing with flat feet.

In a bed at the end of a long ward was a man with a recent fracture of the surgical neck of the humerus which was being treated without splint or apparatus, but by gentle massage. "If the massage gives pain in the treatment of fracture," said the surgeon, "it is doing harm or is being badly done." His experience was that the treatment of such a fracture without retentive apparatus was not only a great comfort to the patient, but it enabled him to recover free movements of the arm at a far earlier period than by the old methods. Dr. Lucas-Championnière then showed a case of fracture of the lower end of the radius which had been treated from the first by massage without splint, and in which the range of movement was highly satisfactory. But I should not be an honest historian if I failed to remark that I found the styloid process of the radius occupying a higher level than it ought to do. Every surgeon knows that the sooner a Colles's fracture is taken off the splint and massage is begun the better; but I certainly think it well to have a splint applied for a week or so, freeing the hand for massage every day. In my experience it is the over-cautious practitioner—the man who fears week after week to leave off the splint—who gets the worst results from this kind of injury.

In the treatment of Pott's fracture without splints Dr. Lucas-Championnière said he had obtained the most surprisingly good results. He had had plenty of these cases, especially in young cavalry soldiers, and these patients were now able to get back into the saddle in about half the time which they used formerly to need. Then he became eloquent upon the French Employers' Liability Act, or whatever it is called. It seemed to be in France much as it is with us; if the workman hurts his hand he is to receive pay for as long as he is unable to use it. The little hurt is quite a godsend to him. He likes being idle, especially when he is paid for it, so why should he be in a hurry to go back? As a matter of fact, he is not in a hurry. He keeps on the free-list as long as he can. Even massage does not cure him. I wished that Mr. Spanton could have heard the description of the ways of the French working man—it was so fully in harmony with the result of his recently recorded experience of the bearing of the Act in England. What was the word which Mr. Spanton gave to this twentieth-century disease—was it not *ergophobia?* The French surgeon wound up with the statement that this workman's law was bad, and that it would have to be altered. Who, I wondered, are going to alter it, the workmen or the employers? Probably, if the former *will* not the latter *can* not.

One extremely interesting case was that of an alcoholic man, of middle age, who had come to Dr. Lucas-Championnière with rupture of almost the entire mass of the quadriceps extensor cruris. Writing from memory, I believe that the rupture was not of recent origin. At any rate, it was operated on, and as the upper end of the muscular mass had been carried a full hand's breadth from its insertion into the patella, and as it was found impossible to bring the ends together, the surgeon had united them across the gap by long strands of thick silver wire, which we could distinctly feel beneath the skin and recognise in the skiagram. It was certainly a most remarkable and useful piece of surgery, for the man was now able to carry on his business as a porter at the central market and was evidently full of vigour. Judging from his appearance I personally should not have ventured to put a knife into his tissues. I should, indeed, have deemed it dangerous to bring a naked light anywhere near him.

Having thus paid a most instructive visit to the wards, we were taken into the operating theatre, where we found a young woman lying on the table calmly waiting for a radical operation to be done upon her femoral hernia. There she lay, among sisters and attendants in white dresses, and with open trays of instruments on one side of her, and with dishes of sponges and dressings on the other. How long she had lain with these unattractive surroundings I do not know. Perhaps my presence in the ward with my surgical friend had caused her time of waiting unduly to be lengthened. At any rate, I felt quite sorry for her, so I went up to her and, for the sake of distracting her attention, congratulated her on her *sang-froid*, and told her that she looked very brave and happy. She said that in this case her feelings were not in harmony with her appearance. And this I could fully believe.

As surgeon to the French Hospital in London I have been constantly struck by the pluck which is shown by French men, women, and even children on their coming into the theatre for operations. When it was my good fortune to be appointed the surgical colleague of my late friend Dr. Achille Vintras, and found that economic arrangements made it necessary for the patients to be brought into the operating theatre before the anæsthetic was administered, I thought that I should have great difficulty in persuading my French patients to bring their courage to the sticking point, and that we should have many a "scene" on operating days. But never once has the courage of a French patient failed him or her. My French patients are, to say the least, possessed of quite as much "pluck" as my own countrymen, and their behaviour fills me with admiration and respect.

At Hôtel-Dieu the anæsthetic given was a mixture of chloroform vapour, oxygen, and air, but the apparatus by which it was served seemed to me to be as complicated as the chassis and engines of a petrol motor. Dr. Lucas-Championnière, however, assured me that it was really quite simple, so I take his word for it. As the patient was being "got under" the surgeon leisurely cleaned his hands, using much soap but little water. I confess that I was surprised at the short time that he took over his own toilet, and at the fact that he did not rinse his hands in antiseptic lotion just before making his incision. He turned to me, however, and said that the old antiseptic faith which he had many years ago acquired from Lister himself had for all this time supplied him with perfect results, and it found him to-day with no desire to go in search of problematical improvements on the original methods. That he found it necessary to use neither india-rubber gloves nor facial mask, and that though the requirements of his service made it obligatory that foul cases should often be occupying beds side by side with aseptic operation cases, a strict observance of the great principles which Lister had taught him carried him along with security as well as safety. That he used Lister's catgut for every suture and for every ligature. That he still swabbed his wounds with 1 in 20 carbolic lotion before closing them, and that he continued to use a simple rubber drain in most of his operations. In short, Dr. Lucas-Championnière is still the faithful and devout, and therefore the successful, disciple of our Lister, and he finds his simple faith sufficient for all needs. What, I wonder, could a surgeon ask more than this, what more need he desire?

Having closed the hernia-wound in the young woman (except for the drainage-tube) the surgeon covered it with gauze and collodion and applied a pad of aseptic peat-wool, which, he said, on account of its absorbent qualities, as well as of its cheapness, was abundantly supplied by the Assistance Publique. As I was washing my hands before leaving the theatre Dr. Lucas-Championnière expressed his regret that he could not offer me a proper towel. "We have," said he, "plenty of sheets and linens of large size, but of proper towels we have none, for our patients have such a fancy for such things that they invariably carry them away if the chance is offered. The best that I can offer you is one of these mean squares of linen which do not seem to offer any great temptation to the patients, 'nous les appelons les mouchoirs de l'Administration!'"

Though it is not my intention to write any account of the visit of the British medical men to Paris further than of the Saturday morning spent at Hôtel-Dieu, still, having mentioned the words Assistance Publique, the great controlling centre of the hospitals of Paris, I would like to say a few words about it. First of all, as a visitor, I would like to express to M. Mesureur, the Director of the general administration, most grateful thanks for a hundred acts of kindness and thoughtfulness which he and his service rendered to us. We shall not forget them.

And then I would say that it seems to me that the time cannot be far distant when our London hospitals, or most of them, must of necessity come under some such central public control. Extravagance in building, needless expense in the many separate schemes of maintenance and direction, enormous sums of money frittered away every week in advertisements and appeals for funds, an obvious want of supervision in the costly matter of drugs, diets, and dressings, and, last but not least, the springing up of a sort of rivalry and competition amongst the various institutions, all seem to suggest that if only to save them from insolvency our hospitals should be placed under authoritative control. The trying to patch up deficiencies in income by making poor people put down a few miserable coppers for medicine; the temporary closing of wards, or the conversion of them into homes for the reception of paying patients; the giving of permission for collecting boxes to be rattled on certain days in the year in the face of every passer-by, and the pestering of householders by heart-breaking appeals for financial help are means as unsatisfactory as they are unsatisfying. And when one sees the quiet, economical, business-like and efficient way in which the Paris hospitals are organised and administered by the Assistance Publique the more desirable a scheme of the same sort appears to be for London. Probably the King's Hospital Fund is already working towards that end.

In conclusion, I would say that the visit of the British medical men to Paris has been a perfect success in every way. We have been received in the most charming, courteous manner and treated in the most princely fashion. To say that our *confrères* have been thus kind to us is but a cold expression of what one would like to say. And as I look back upon our delightful visit—full of most happy remembrances—I cannot get away from the feeling that when our French brethren visited us last autumn we, personally and collectively, made no adequate effort to render their visit enjoyable. But when, at the magnificent banquet which they gave us on the last night of our visit, I was thus unburdening my mind to my French neighbour at the table he gently replied, "Why, the greatest compliment which you could possibly have paid us in connexion with our journey to London was this prompt and friendly return of our visit." And I know that he meant it!

BRISTOL HOSPITAL SUNDAY FUND.—At a meeting of the council of this fund held on May 18th it was reported that in 1905 there had been collections at 425 places of worship; of this number 55 were new ones. The total amount received was £2053, being £326 in excess of the amount collected in 1904 and £280 more than the largest sum hitherto realised. Of this sum the Bristol Royal Infirmary has received £805, the General Hospital £675, the Children's Hospital £261, and the Eye Hospital £120. £108 were divided among smaller medical charities, giving a total of £1969 which has been already distributed.

RUSSIAN MEDICAL STUDENTS' INTERRUPTED STUDIES.—The conference of the Imperial Military Medical Academy is continually receiving requests from medical men and pharmacists serving at the front after having had their examinations interrupted by the military requirements that they should be allowed to finish their examinations for their respective callings after their return. They have been informed that the examinations which they have already passed will still stand to their credit but that on their return to St. Petersburg they will have to petition afresh, properly supported with documents.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XIII.[1]

THE PRESENT STATE OF MEDICAL EDUCATION.

The Universal Scheme.—A Tabular View of the Five Years' Curriculum.—The Societies of Apothecaries.—The Registration of the Student.—The English Colleges resist the General Medical Council.—Some Comparisons.

THE state of the medical profession in respect of its professional position has now been described and we see that it is a sound one, though under its various aspects there are many things that require alteration, and though grave abuses exist which could be righted immediately if only the mischief of them were properly appreciated. A profession which brings to so large a proportion of its followers a fair measure of practical success, which can be pursued in such different environments, and which offers in its mere pursuit such high intellectual and moral pleasures, cannot possibly be regarded as other than a good one, even if it may be easy to show many directions in which it might be bettered. In fact, the obviousness of the drawbacks justifies us in believing that alteration for the better may be expected. But no picture of the present position of medicine, either of its practice or of its relations to the public, should be given without dealing with medical education. The solution of the troubles of the medical life, almost as much as the intellectual pleasures of that life, lie in the acquisition of scientific knowledge and the practical power to apply the same. It is urgently important that we should all, as a profession, appreciate how much depends on the maintenance of a high level of professional learning. Only in this way can we deserve the consideration of the public and command a respectful hearing when seeking any improvement in the conditions of medical practice.

The position of medical education in Great Britain and Ireland at the present day is in a similar plight to the professional position. It is in many particulars open to amendment, but the principles as laid down by the statutory educational bodies, which are numerous and endorsed by the General Medical Council, appointed by Act of Parliament as the coördinating authority, are sound. The desire of the General Medical Council ever since its institution has been to secure an adequate curriculum for the medical student, so that the medical practitioners of England, Scotland, and Ireland, through whatever qualifying body as a medium they might enter the medical profession, should be up to a due, even to a high, standard of efficiency. As this has also been the aim of the various qualifying bodies, the great majority of which were in existence years before the institution of the General Medical Council, the educational work of the Council has been simplified. The Council, however, has recently been confronted with difficulties mainly arising from the general development of medical knowledge and the consequent increase of subjects for which space has to be found in the student's curriculum, but due also to a want of complete accord in the aspirations of all the qualifying bodies and to the special circumstances which surround the medical student at the London schools.

The scheme which the various qualifying bodies have adopted by a sort of general consensus of opinion, and which is approved of by the General Medical Council, may be summarised as follows. Firstly, the student must pass a preliminary examination, which is not of a stringent character, in fact, it seems that almost any initial test answers the purpose. Secondly, he must enter upon a five years' curriculum from the date of passing that [illegible] must submit himself to [illegible] entific examination, an [illegible] final examination. The [illegible] the subjects of which are chemistry, botany, biology, and physics, should be passed at the end of the first year; the intermediate examination, the subjects of which are anatomy and physiology, should be passed at the end of the third year; the final examination, the subjects of which are medicine, surgery, and obstetric medicine, should be passed at the end of the fifth year. Hence, the first year of the medical student's curriculum should be devoted to the more or less elementary study of the sciences which he will later find are necessary to the comprehension of medicine—the ancillary sciences; the next two years should see him in the dissecting room and the physiological laboratory learning to appreciate the shapes, dispositions, relations, and functions of the normal human body as the only method of detecting and understanding any lapses into disease or pathological conditions due to injury; and the last two years of the curriculum will be spent in the wards and out-patient departments of a hospital.

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., and XII. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), May 6th (p. 1218), 13th (p. 1287), and 20th (p. 1375), 1905 respectively.

The medical curriculum has been extended in obedience to the vastly greater scientific and professional equipment that is now required of the medical practitioner in whatever branch of medicine he may be called upon to practise. Many years ago it was extended from three years to four, while a change made 12 years ago extended it from four years to five. Each change necessitated a re-arrangement of their examinations upon the examining bodies, and the result is that at the present moment a great similarity appears in the educational course of all of them, every student having the same subjects to read and to acquire practically in the same space of time. Consequently the state of medical education in the three countries at the present day can be discussed as a more or less uniform thing, arranged upon a definite pattern by the respective qualifying bodies and supervised by one authority—the General Medical Council. This uniformity may be insisted upon a little, for it is exactly what would *not* be expected to exist where over 20 educational institutions, having their homes in different countries and drawing their *clientèle* from different classes, compete against each other for the patronage of the student requiring a qualification. The fact that at the present time, under a system in which many faults of detail can be found, a high general level of education is maintained, making down-grade competition very improbable, is striking. And it has a forcible bearing upon proposals for reform because it suggests that the existing condition is a sound one and that nothing is required save to simplify it (1) by removal of the anomalies that are due to its growth into a whole from many separate directions and (2) by resistance to unnecessary developments undertaken with the vain hope of examining students, whose season of acquisition must be limited, in all the unlimited extensions of modern medicine.

The simplest manner to obtain a bird's-eye view of the present state of medical education in England, Scotland, and Ireland will be to consider the curriculum of the student as enjoined by the different qualifying bodies in connexion with the supervision exercised over this curriculum by the General Medical Council. The part played by the General Medical Council is to admit the student to the roll of the profession when he is successful in obtaining the necessary qualifications and to see that those qualifications are adequate. The part played by the qualifying body will be to examine him at different stages of his career. The fact that there is a general likeness between all the educational plans of the qualifying bodies enables the subject, which in a manner bristles with detail, to be treated with some brevity. This will be seen by an examination of the following two small tables. The first table sets out the examination scheme of three universities, those of Cambridge, Edinburgh, and Dublin; the second the examination scheme of the Royal Colleges of Physicians and Surgeons of the three countries. The examinations of the two Societies of Apothecaries will be found separately treated. The exact details of all the examinations of all the bodies are published annually in the respective calendars and are summarised, also annually, in the Students' Numbers of THE LANCET. There is no need to recapitulate particulars which have been published so frequently and which are so completely accessible. I have chosen, to illustrate the homogeneity of all the educational schemes laid down for the medical student, the schemes of six educational bodies, a university and a corporation in each division of the kingdom. Looking a little more closely into the details of these schemes we see their similarity to each other, and in comparing them with the schemes of other bodies we see again that the differences are mainly superficial.

The first step in the education of the medical student is his registration and the registration of a student is not compulsory. The General Medical Council has laid down regulations in reference to the registration of students which are very precise but there is nothing in the Medical Acts making it incumbent upon the student to enter his name with the Council at the commencement of his studies. It is sufficient for his name to be enrolled by his qualifying body upon passing one of the statutory examinations; that body becomes responsible for not admitting him to his final examination until five years later.

The preliminary examination, as provided for by the General Medical Council, supposing the student not to begin his studies by passing any recognised test at his university or corporation, is of fair scope. The following is the schedule:—

1. English language, including grammar and composition.
2. Latin, including grammar, translation from unprescribed Latin books, and translation of English passages into Latin.
3. Mathematics, comprising arithmetic, algebra, including easy quadratic equations, geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions.
4. One of the following subjects: (*a*) Greek, (*b*) a modern language.

A degree in arts of any university of the United Kingdom or of the colonies or a certificate of having passed the final examination for a degree in arts or science of any university

TABLE I.—THE EXAMINATION SCHEME OF THE UNIVERSITIES.

University.	Matriculation.	Preliminary Scientific Examination.	Intermediate Examination.	Final M.B. and B.C. Examination.	M.D. Examination.	M.C. Examination.
Cambridge.	Medical student begins curriculum by passing the First Examination of the Arts course, by graduating in Arts, or by obtaining a certificate from the Oxford and Cambridge Examining Board.	First Examination for M.B: Chemistry, Physics, and Biology.	Second Examination for M.B.: Anatomy and Physiology. The standard is high.	Third Examination for M.B.: Part (1) Pharmacology and General Pathology. Part (2) Surgery, Midwifery, and Practice of Physic. The two parts may be taken separately.	Presentation of thesis and writing of an extempore essay.	Examination in Operative Surgery. An extempore essay has to be written.
Edinburgh.	A Matriculation Examination has to be passed of ordinary standard implying a knowledge of classics and English.	First Examination for M.B.: Chemistry, Zoology, Botany, and Physics.	Second Examination for M.B.: Anatomy, Physiology, Materia Medica, and Therapeutics.	Final Examination for M.B. and B.C.: Part (1) Pathology, at end of fourth winter session. Part (2) Surgery, Medicine, Midwifery, Forensic Medicine, and Hygiene, at end of fifth year.	Presentation of thesis and Examination in Clinical Medicine.	Examination in Operative Surgery. A thesis has to be written.
Royal University, Ireland.	The Matriculation Examination is of similar standard to that of other universities.	First Examination for M.B.: Systematic Chemistry, Zoology, Botany, and Physics, or Natural Philosophy.	Second and Third Examinations for M.B.: Part (1) Anatomy, and Physiology, and Practical Chemistry at the end of the second medical year if one year has elapsed since passing the First M.B. Part (2) At the end of the third medical year: Anatomy, Physiology, and Materia Medica.	Final Examination for M.B. and B.C.: Part (1) Medicine, Therapeutics, Pathology and Hygiene. Part (2) Surgery and Surgical Anatomy. Part (3) Midwifery and Diseases of Women. Each part of the examination must be passed as a whole.	A clinical examination. Bedside diagnosis and treatment of cases.	Written and clinical examination in all subjects.

TABLE II.—THE EXAMINATION SCHEME OF THE CONJOINT BOARDS OF ENGLAND, SCOTLAND, AND IRELAND.

Name.	Entrance Examination.	First Professional Examination.	Second Professional Examination.	*Third Professional Examination.*
English Conjoint Board (Royal College of Physicians of London and Royal College of Surgeons of England).	Any examination approved by the General Medical Council.	Chemistry and Physics, Practical Pharmacy, and Elementary Biology. Examination can be taken in three parts and Pharmacy can be taken at any stage in the curriculum.	Anatomy, Physiology and Histology. Both subjects must be passed together.	(a) Medicine, Pharmacy, Forensic Medicine, and Public Health. (b) Surgery and Surgical Anatomy. (c) Midwifery and Diseases of Women. Examination can be taken in three parts and Part (c) can be passed at end of fourth year.
Scottish Conjoint Board (Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow).	Any examination approved by the General Medical Council.	Chemistry, Elementary Anatomy and Physiology, and Histology.	Anatomy, Physiology, Materia Medica, and Pharmacy.	[illegible]
Irish Conjoint Board (Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland).	Any examination approved by the General Medical Council. Colleges also hold a preliminary examination.	Chemistry, Physics, and Elementary Biology.	Anatomy, Physiology, and Histology	[illegible] themselves for examination in the subjects separately.

in the United Kingdom is considered a sufficient testimonial of proficiency for admission to the Students' Register or to the commencement of medical study. There [illegible] ose examinations in general [illegible] General Medical Council as [illegible] medical student. At the Universities of Oxford and Cambridge graduates are admitted to registration, but the undergraduates of these universities are exempt from any preliminary examination before commencing medical studies if they have passed certain standards in the local examinations, have obtained certificates from the Oxford and Cambridge Schools Examination Board, or have passed the first and second tests for the ordinary arts degrees—viz., "*smalls*" or "*moderations*" at Oxford, "little-go" or "gene [illegible] Universities of London, Victori [illegible] the Royal University of Ireland, [illegible] all have a matriculation, and those who have passed this test at their respective universities can commence their medical studies. The University of Dublin has an entrance examination, while the Universities of Edinburgh, Aberdeen, Glasgow, and St. Andrews have an inaugurating test for their students in the preliminary examination of the joint board of examiners for graduation in arts or science or medicine and surgery. The College of Preceptors in England holds a preliminary examination for medical students and also a general examination for first-class certificates. Satisfaction of either test will admit the student to his studies. In Ireland the middle and senior grade examination of the *Intermediate Education Board*, in Scotland the leaving certificates of the Scottish Education Department, and in Wales the senior certificate of the Central Welsh Board will do the same. There are regulations by which students at colonial, Indian, and foreign universities can obtain admission to the Students' Register, concerning which it is enough to say that the General Medical Council has to be satisfied of the adequacy of the tests. The Conjoint Examining Board of the Royal Irish Colleges holds an examination which is approved of by the General Medical Council but there is nothing of the sort at the other two Conjoint Boards.

The medical student, as we have said, need not register as such. What is necessary is that he shall pass one of the approved examinations in general knowledge before entering upon his five years' curriculum and that he should not be [illegible] years, but upon it hangs a very important issue, one that has been recently the subject of difference of opinion between the English Royal Colleges and the General Medical Council—a difference of opinion now in abeyance rather than settled. The General Medical Council has objected to the standard of scientific education required at the preliminary scientific examination of the English Conjoint Board. The English Conjoint Board accepts certificates that its students have *undergone instruction in* chemistry, botany, and physics at certain named public schools and institutions. Supposing a student who has passed his entrance examination in general education possesses satisfactory proof of having attended courses in preliminary science at one of these schools he can be admitted to the preliminary scientific examination of the English Conjoint Board, and, if he passes the examination, he can at once proceed to the study of anatomy and physiology, having apparently shortened his period of professional study to four and a half years by doing his preliminary scientific work *at school and counting the time so spent as* six months of his medical curriculum. Some may say, where is the harm? There is no harm if the preliminary scientific examination is sufficiently difficult. To practical minds it cannot matter a tittle where the student acquires his knowledge of the ancillary scientific subjects if only he acquires sufficient, but this is the point upon which the General Medical Council desires to be satisfied. The Council is the central authority and it is its duty to make certain that the curriculum cannot be abbreviated in a manner that is either unjust to the public or advantageous to some qualifying bodies more than to others. The difficulties are considerable. The General Medical Council for practical reasons cannot watch over the scientific courses given in public schools, so that the only way in which its power and responsibility of supervising medical education can be exercised is by insuring that the examination in the work purporting to be done at such schools is particularly rigid. The English Conjoint Board has resented the strictures of the General Medical Council upon the preliminary scientific examination of the Board, and this feeling is intelligible, for the Board has taken great trouble *to insure* that the examination is adequate and that the instruction at the various schools is good. Negotiations between the two parties were not conducted with complete urbanity. No one who knows anything of medical education can possibly fail to appreciate the fact that the professional examinations of the English Conjoint Board are remarkably thorough and well conducted. The men who pass the final examinations of this Board meet with the most uniform success in other competitive examinations and in every way show that they are able to hold their own with the possessors of so called "honour" degrees. This fact makes it especially *galling for the Board to have its* preliminary scientific examination called in question, and the Board would probably desire to take up the attitude that the General Medical Council, being concerned only in seeing that the men who apply for registration as qualified medical men are duly instructed, should confine its inspection of examinations to the finals. The contention does not hold water. It is not possible to say that education begins in one place rather than in another, and it is the manifest duty of the General Medical Council to inspect any portion of the curriculum of any one of the qualifying bodies and to demand any necessary alteration. *The English* Conjoint Board, having lent itself to the appearance of shortening the medical curriculum, ought not to consider the General Medical Council to be inspired by any unfair animus if the Council reflects upon the character of the preliminary scientific training demanded by the Board; and the action of the Board in signifying that for the future its medical students need not register seemed at one time to be likely to meet with reprisal. A Bill was projected by the General Medical Council making the registration of the medical student compulsory, but the measure was dropped when it was found that the English corporations were not alone in their attitude but that some of the other qualifying bodies also objected to the proposed legislation. The zeal of the Council for registration of the student was not, as a matter of fact, due so much to a desire that every student should commence his studies upon a national students' roll as that he should contribute a fee for registration to the depleted coffers of the Council. It may have been consciousness of this fact that led the Council to drop the Bill with readiness.

The two tables show the scheme of the medical curriculum of the various universities and corporations and show it to be uniform. The educational schemes of the two Societies of Apothecaries are not quite on the same model and can be best described by brief summaries.

SOCIETY OF APOTHECARIES OF LONDON.—There are two examinations for the Licence of this Society—the Primary and Final. The Primary Examination consists of two parts. The Licence entitles the holder to registration as being qualified in medicine, surgery, and midwifery. Part I. comprises Ele*mentary Biology; Chemistry and Chemical Physics, including* the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Materia Medica. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of 12 months' practical anatomy with demonstrations and these subjects cannot be taken separately. The Final Examination is divided into two sections. Section 1 consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. includes the Principles and Practice of Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology and Diseases of New-born Children, and the Use of Obstetric Instruments and Appliances. Section 1 of the Final Examination cannot be passed before the expiration of 45 months after registration as a medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the society. Section 2 of the Final Examination consists of two parts. Part I., Clinical Surgery; Part II., Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the end of the fifth year.

APOTHECARIES' HALL OF IRELAND.—The Licence of this Hall is granted to students after five years of professional study. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery. There are four professional examinations. The First Examination includes biology, physics, theoretical and practical chemistry, with an examination at the bench. Pharmacy is put down in this examination, but it may be taken at any of the first three examinations. Candidates holding a pharmaceutical licence are exempt from this subject. Osteology is also a subject of the first professional examination. The subjects for the Second Professional Examination are anatomy, materia medica and therapeutics, physiology, and practical histology. The Third Examination consists of pathology, materia medica if not taken at the Second Examination, medical jurisprudence, and hygiene. The Final Examination includes clinical and theoretical medicine, surgery (with operations), ophthalmic surgery, midwifery, and gynæcology.

It will be seen that the curriculum at the three Universities given in Table I., which is typical of that at the remaining Universities, is practically identical with that of the Conjoint Boards. At the Universities the entrance examination, in the form of an arts degree, a matriculation, or a certificate, generally demands more than the minimum approved by the General Medical Council, but none of the Universities, save the University of London, makes any serious demand upon the medical student at the outset of his career. The First Examination for the M.B., or Preliminary Scientific Examination, at the Universities corresponds with the First Professional Examination at the Colleges, which is not strictly a professional examination at all, but an examination in ancillary subjects. The Second Examination for the M.B., or Intermediate Examination, at the Universities corresponds with the (so-called) Second Professional Examination at the Colleges. This examination at Oxford is called the First Examination for the M.B., which designates the examination as the first strictly professional examination. The Final Examination for the M.B. at the Universities corresponds with the Third Professional Examination at the Colleges. In each case the same subjects are set and the standards are roughly similar, the extent to which they may be raised being left to the individual university or corporation, while the superintendence of the General Medical Council prevents them from dropping too low. The same may be said of examinations for the Licences of the Societies of Apothecaries, where more or less an identical system of subdivision of the professional subjects prevails.

The fact that medical education, all along the lines which converge in the qualification of the student, should be so homogeneous much simplifies the task of the General Medical Council in its efforts to maintain a high standard, and should give pause to those who call out that medical education is chaotic because certain minor anomalies exist. Yet the differences which exist in the curricula are real and do harm. The Matriculation Examination of the University of London, for example, is much more difficult than any other of the examinations which confront the students on the threshold of their medical careers. It has been modified of late but there is no doubt that far more application is required from the student to pass this examination than is required to pass any of the other entrance examinations, and the student who has passed it is able to assimilate with greater ease the subjects of the purely professional examinations, while at every other portal to the medical profession the student is allowed to enter with too little ceremony. The examinations of the College of Preceptors and of the Scottish Education Department, the Cambridge "little-go" and the Oxford "smalls" are not tests of general knowledge in the least, and the lad who has passed no more severe ordeal than these has not proved himself to be sufficiently equipped in general knowledge. His classical smattering and his scraps of mathematics will not stay by him, and if they did they would not render his future work easier for him. If the University of London has gone too far none of the other qualifying bodies has gone far enough, and the General Medical Council might well insist upon an all-round raising of the standard of general education. The Preliminary Scientific Examination is also higher at the University of London than elsewhere, but the tendency at all the examining bodies is to improve this examination, especially in the direction of chemistry—a healthy sign, the inter-relation of chemistry and physiology, biology and pathology, having now become so close. The Intermediate Examination, called First M.B. at Oxford and Second M.B. at all the other Universities, is a thorough one in every instance. The student is sometimes allowed to take the two subjects separately, but it is significant that at Cambridge, where the standard of physiology is high, they must be taken together. And it is far preferable that they should be so taken. The highest standard in anatomy is that demanded by the Royal College of Surgeons of England in the intermediate examination for the degree of Fellow, but the Fellowship course is a purely honour course and for that reason is not included in the preceding tables.

In the final examinations there are a few variations from type which call for notice. At the University of London there is a definite examination for the M.D. degree and the medical man is desired to specialise in that degree by electing to be examined under five different headings. In the examinations for the M.B. degree at Edinburgh a certain amount of specialisation is invited, while at Birmingham the examination is much split up into groups, a proceeding which doubtless will be convenient to the student but which cannot be commended. In Edinburgh the subject of pathology, and in Glasgow the subjects of pathology, jurisprudence, and public health, can be separated from the other final subjects and passed at the end of the fourth year. The same arrangement, with the addition of applied anatomy and physiology, holds good at the University of Dublin.

The scheme of medical education in England, Scotland, and Ireland to-day is very nearly uniform. The entrance to practice is better guarded at one door than at another but everywhere the curriculum is well devised and may turn out good men. Moreover, the various educational bodies are zealously and constantly watched by the General Medical Council, which is never accused of being supine in respect of educational supervision. The final examinations of all the universities and corporations are tested periodically by the visitors and inspectors of the Council and from the report which these officials make from time to time to the Council a very exact idea of the present state of medical education in the various centres can be obtained. In the next chapter will be found a summary of the last visitations made.

(To be continued.)

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on May 11th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The following Members who were elected to the Fellowship at the last meeting were admitted as Fellows: Duncan Burgess, M.B. Cantab.; Thomas Watts Eden, M.D. Edin.; Wilfred John Harris, M.D. Cantab.; Bedford Pierce, M.D. Lond.; *James William Russell, M.D. Cantab.; James Harry* Sequeira, M.D. Lond.; Harold Batty Shaw, M.D. Lond.; Edmund Ivens Spriggs, M.D. Lond.; William Barnett Warrington, M.D. Lond.; Arthur Whitfield, M.D. Lond.; and Robert Arthur Young, M.D. Lond.

This being the only business on the agenda the PRESIDENT dissolved the Comitia.

REPORT OF THE GERMAN COMMISSION ON ANTITYPHOID INOCULATION.

THERE has reached our hands in the course of the last few days the report of a committee of bacteriologists convoked at the instance of the Prussian Government to consider and to report upon the question of antityphoid inoculation in connexion with the German army. The committee included among its members, in addition to Professor Koch, Professor Kolle (well known for his work in connexion with this question) Professor Dönitz, Professor Kirchner, and the Director of the Institute of Infectious Diseases in Berlin—Professor Gaffky. The report, which has been drawn up by the last named, considers the question referred to it under four different aspects. It deals first with the rôle of antityphoid inoculation as a sanitary measure; secondly, with the question of the best inoculation procedure; thirdly, with the question as to whether there is any risk or danger attaching to the inoculations; and lastly, with the question as to what ought to be done to obtain further information on the subjects at issue.

The conclusion arrived at is that the subject of antityphoid inoculation is one of national moment. It is recognised that while the incidence of typhoid fever among the German troops is in time of peace very light, typhoid fever would come to be an all-important factor in connexion with a European war and a still more important factor in connexion with war carried on in tropical or subtropical countries. It is, in the opinion of the committee, and for these reasons, a matter of urgency for the German Government to carry out researches and to collect all possible information with regard to antityphoid inoculation. These considerations which hold good in the case of Germany ought manifestly to come home to us in an even more intimate way in view of the eventuality, which has recently so much occupied the public mind, of our having to place half a million soldiers in the field for the defence of the North-Western frontier of India. And even that eventuality apart, the question of the possibility of inoculating successfully against typhoid fever is to us who have to keep the larger part of our army permanently in tropical and subtropical countries manifestly of more intimate concern than it is to any other nation.

But, it will be urged, it is precisely the question of the possibility of such successful inoculation that has been at issue. On this question the conclusions arrived at by the German Commission will be of interest. The committee begins by dealing with the experiments on animals and points out that the possibility of conferring protection upon animals against many times the lethal dose of a culture of the bacillus typhosus is beyond dispute. It then deals with the experience of antityphoid inoculation in connexion with the British Army. Pointing out that this experience has been accumulated by the "energy of English (army) doctors put forth in response to the continually reiterated stimulus coming to them from A. E. Wright, late professor in the Army Medical School, Netley," and expressing its appreciation of "the admirable tenacity," which has characterised his work, it proceeds to pass in review the history of antityphoid inoculation in the British Army. It refers in particular to the abolition of the process by the Medical Advisory Board; to the favourable judgment passed on the inoculation by the antityphoid committee of the College of Physicians; to the continued opposition of the Advisory Board; to the final re-introduction of the inoculations into the army on the recommendation of the antityphoid committee appointed by the Secretary of State; and to the retirement of Dr. Wright from that committee by reason of his dissatisfaction with the failure to provide an organisation for the adequate scientific control of the inoculations.

Finally comes the verdict on the question of the efficacy of antityphoid inoculations. Our readers will like to have the *ipsissima verba*. The verdict is worded as follows:—

> On a survey of the already mentioned scientific observations con- [illegible] trustworthy data, with regard to the degree and duration of this protection.

Passing from this general judgment to the discussion of the technical question as to the relative advantages of single or double inoculation and of preparing the vaccine from agar or broth cultures, the committee recommends the employment of two successive inoculations and of a vaccine made from agar cultures heated from 60° to 65°. Dismissing the question of procedure, it then embarks upon the consideration of the question as to whether there is any risk of any permanent injury to health from inoculation. It decides that there is no such risk; and it points out that in view of the opposition which antityphoid inoculation has encountered in certain quarters in England it is quite [illegible] have been alleged against [illegible] spect would certainly have [illegible] ute of Infectious Diseases [illegible] ndertake in relation to the [illegible] bility in connexion with the [illegible] introduction of the inoculation into the German army and the carrying out of the inoculations in the cases of German troops proceeding to South-West Africa.

It will be seen that the conclusions of the German Commission are substantially those of the successive committees the verdicts of which led to the re-introduction of antityphoid inoculation in the British army after it had been abandoned by the Medical Advisory Board. With respect to that further research and careful scientific control of the inoculations which have, as the German Commission notes, always been insisted upon by Dr. Wright as essential to the perfecting of antityphoid inoculation, we may learn the proper course of action from that already undertaken in Germany. There a considerable staff of bacteriologists in the Institute of Infectious Diseases—one of the most famous and best equipped laboratories in the world—is now occupied in research in connexion with antityphoid inoculation, while some 2000 inoculations have already been carried out in connexion with troops despatched to South-west Africa. Here the care of antityphoid inoculation is delegated to a committee which, as at present constituted, includes two members of the hostile Advisory Board. The policy of this committee appears to be to sit down and to await the results of the inoculations which were carried out in a single regiment last autumn. And the irony of fate has appointed that the particular regiment should now be quartered in a station which is practically never visited by typhoid fever. While we are very far from suggesting that a regiment should be sent to a hotbed of typhoid fever for the purpose of testing the efficiency of antityphoid inoculation, we feel that the medical policy which proposes to investigate antityphoid inoculation and which omits to apply the test in the stations where typhoid fever is always rife is probably lineally descended from the policy which, in association with the abolition of antityphoid inoculation in the army, suspended also the collection of all further returns with respect to the incidence of typhoid fever in the many thousands of inoculated who still remained in the army.

If the policy with respect to antityphoid inoculation is as stated above it appears to us to rival in ineffectiveness the medical policy which seeks to stem the plague, which carried off within a year over 1,000,000 of our fellow subjects, by the agency of a commission which proposes itself to remain in London and to delegate to assistants the actual work of research that can only be carried out in India.

MEDICINE AND THE LAW.

Two Cases of Alleged Death from Poisoning, by Arsenic and Strychnine respectively, in the United States.

Mr. G. M. Beringer has recorded in the *American Journal of Pharmacy* for February the results of toxicological examinations in two interesting cases of alleged death from poisoning. In the first case the defendant was charged with the murder of her step-daughter, a frail child, aged two years and nine months, who died without having had sufficient medical attendance and in circumstances that were considered suspicious. One evening the defendant called on a neighbouring physician and said that the child was suffering from a slight cold. He prescribed a few small pellets of aconite. An hour later she again called on the physician and requested his immediate attendance as she said the child had had a convulsion. On arrival at the house the physician found that the child was dead but there was no evidence of convulsions. He discovered numerous bruises on the body, and as the neighbours spoke of the step-mother's harsh treatment towards the child he referred the case to the coroner. The undertaker, however, was promptly summoned. He arrived at midnight and immediately embalmed the body, injecting about one pint of fluid into the abdominal cavity near the navel. The coroner issued a burial permit and the child was buried, but through the suspicions of the child's maternal relatives, who demanded an official investigation, the body was disinterred and a post-mortem examination was made by Dr. R. H. Parsons and Dr. A. H. Small. They reported that they found the nose broken, the eyes black and blue, the upper lip deeply cut, the left ear partly torn from the scalp, and numerous other bruises on the body and the head. They considered that meningitis was the direct cause of death. Separate chemical examinations of the viscera and other parts were made by Mr. Beringer and by Professor Frank X. Moerk, the former finding nearly 12·5 grains of arsenious oxide and the latter 17·5 grains in the materials examined. Suspecting that the embalming fluid was an arsenic solution a sample was procured from the undertaker who stated positively that it was part of the same lot that was used for embalming the body. Analysis showed it to contain formaldehyde and potassium nitrate, but it was entirely free from arsenic. At the trial the State contended that death was due to meningitis, produced either by the wounds from cruel beating or by arsenical poisoning or by a combination of both. For the defence it was claimed that the arsenic was introduced after death by the embalming process. This contention was strengthened by the evidence of the undertaker who, when called for the defence, stated that he occasionally used two other embalming fluids, both containing arsenic. The jury acquitted the defendant.

In the other case a woman was charged with having killed her husband by the administration of strychnine. The evidence showed that the husband, a healthy man of a cheerful disposition, had a slight attack of diarrhœa and vomiting on the day of his death. His wife drove to a neighbouring town and obtained from a physician some tablets containing calomel, morphine sulphate, capsicum, ipecacuanha, and camphor; also a liquid containing fluid extract of gentian and syrup. She inquired whether it would be necessary for her to obtain a prescription in order to purchase some strychnine. She later purchased 30 grains of strychnine from a druggist in the town, stating that it was required for killing rats. She inquired there how much of the poison it would take to kill a man. On returning home she administered to her husband, in the presence of a friend, one-third of a teaspoonful of a brown powder. The patient complained of the intense bitterness of the medicine. After a short time a second and similar dose was administered and the husband again complained of the bitterness. Soon after this he became restless, the usual symptoms of strychnine poisoning followed, including twitching and jerking of the muscles and convulsions, and at 7.15 P.M. he died. Immediately after the death of her husband the defendant made conflicting statements as to the disposition of the strychnine, stating that she had burned it in the presence of three witnesses who on their part contradicted her statement. The post-mortem examination failed to reveal the cause of death; a chemical examination of the organs showed the presence of strychnine amounting to about one-sixth of a grain in the materials examined. At the trial the State alleged as motives for the crime the acquirement of a sum of $1000 through an insurance policy on the husband's life and the desire of the defendant to marry a farm hand with whom for a long time she had maintained improper relations. The *liaison* was admitted by the defence, as also that death was the result of poisoning by strychnine, but the defendant testified that the strychnine had been placed in a desk in the sitting-room, and that her husband must have taken some of the poison while the rest of the family were at dinner in an adjoining room. She explained the powdered condition of the medicine by the fact that the envelope in which the physician had placed the tablets had fallen on the floor of the carriage and had accidentally been trodden on by her heel on the way home. The jury considered this plea as establishing a reasonable doubt and as sufficient to justify them in rendering a verdict of acquittal.

What is Pure Milk?

As a result of the deliberations of the departmental committee of the Board of Agriculture which sat in 1900 the Sale of Milk Regulations were issued during the next year. They affirmed that milk to be allowed as genuine must contain not less than 3 per cent. of milk fat and not less than 8·5 per cent. of other milk solids. These percentages are recognisedly a minimum and lead the unscrupulous vendor into the temptation to skim or to dilute the native product to a degree which will just keep him within the letter of the statutory provisions. If a specimen of milk upon analysis exhibits a less percentage than the regulations demand there is a presumption against the seller of adulteration, dilution, or abstraction; if, however, he can prove satisfactorily that the specimen was just as the cow yielded it this presumption can be rebutted by him. To the medical man the statutory definition as to the proportional contents of milk is little short of an anomaly; he knows the variations in the relative constituents of human milk, and he is assured by farmers that cow's milk is similarly variable; a change of the diet or the shed of an animal, being "bulled," maltreatment, and many other causes are alleged to weaken the quality of genuine milk, some of these probable causes having been corroborated by skilled analysts. When a local sanitary authority has found milk to be deficient in the usual solids, whether the vendor is liable or not rests with the local justices to determine. In 1902 (Smithies *v.* Bridge) where milk was proved to be untampered with, this fact did not excuse the presence of only 2·09 per cent. of milk fat. In Ireland the regulations demand the same percentage as in England, so that when in September, 1904, at Skibbereen, it was proved that there was less than 3 per cent. of milk fat the vendor was not allowed to escape the penalty. Recently in the King's Bench Division (Wolfenden *v.* McCulloch) it was decided that the conviction must be upheld as the liability for selling inferior milk was determinable by the justices; in this case there were 2·81 per cent. of milk fats and 8·94 per cent. of other solids. Lastly, a metropolitan stipendiary magistrate has just allowed the plea adduced by a solicitor and supported by the *ipse dixit* of dairymen, that a deficiency of milk fat to the extent of 18 per cent. was accounted for solely by the fact that the cow from which the milk was drawn was being "bulled" at the time. There is weighty legal opinion, however, to the effect that justices may convict if they consider that the quantitative constituents of the sample of milk, apart altogether from the presence of preservatives, are so different from the normal that the article is not "of the nature, quality, or substance" as the thing demanded; probably *this view* will be tested before long in order to settle the present uncertainty on a question of great public importance.

The Medical Man, the Coroner, and the Pathologist.

When the two murderers, Albert and Alfred Stratton, were hanged at Wandsworth gaol on May 23rd the post-mortem examination was made by Dr. L. Freyberger. It has been suggested in justificatio [illegible] man instead of such a [illegible] Act directs, that the e [illegible] experience may be desirable in obscure cases where the cause of death is difficult to determine. It hardly seems likely that exceptional difficulty will arise in ascertaining the cause of death where a criminal has been executed by hanging, but such must apparently be considered to be the view of Dr. Freyberger's employers.

St. Thomas's Hospital and the Observations of a Coroner.

At an inquest held at Lambeth on May 22nd the death of a domestic servant, aged 24 years, was inquired into. The girl was found wandering in the streets on Easter Monday by the police and was removed to the Marylebone workhouse infirmary where her condition improved. Mr. Bernard Pitts, in whose employment she had been, interested himself in her case, and asked Dr. Percy Smith to examine her as to her mental condition. Dr. Smith reported that in his opinion she was rational and would not be a fit case for a lunatic asylum but would be better under observation at a hospital and accordingly Sir John Parkington, a magistrate, signed an order to allow her removal from the workhouse infirmary. A nurse at St. Thomas's Hospital who gave evidence at the inquest said that the deceased was admitted to one of the wards and was watched but that after the patients were settled for the night her attention was called to the deceased who had left her bed. The witness then saw her open the door on to the balcony, pass out, and cast herself over, killing herself in her fall. Mr. [illegible], said that he regarded [illegible] his intention of com- [illegible] Lunacy with regard to it, adding to his other observations that he was not at all satisfied with the way the case was removed from a place where special treatment could have been given to one where there were no special conveniences for lunacy cases. The jury, however, declined to accept Mr. Troutbeck's view and added to a verdict of "Suicide while of unsound mind" a rider to the effect that they considered that the authorities of St. Thomas's Hospital were free from blame in the matter. With this exoneration Mr. Troutbeck said that he could not in any way concur. If Mr. Troutbeck was seriously of the opinion that the hospital authorities or any one else, either through any negligence or callousness or by action due to some sinister motive contributed to the very unfortunate incident recorded, he was no doubt justified in expressing his views. The jury, however, evidently dissented from him, and it would appear that so far from any indifference being shown as to the poor girl's case very exceptional interest was taken in it, and that unusual attention and care were accorded to the deceased. Moreover, Mr. Pitts, Dr. Smith, and Sir John Parkington can hardly be accused of having been influenced by any motive save the desire of doing for the patient, according to their judgment, the best that lay in their power. The Commissioners in Lunacy, to whom Mr. Troutbeck apparently intends to report the matter, can hardly take a different view as to the motives which actuated everyone concerned.

THE GERMAN SURGICAL CONGRESS.[1]

THE German Surgical Association held its annual meeting from April 26th to 29th in Berlin, Professor **KRONLEIN** (Zürich) being in the chair.

Treatment of Acute Inflammation.

Professor **BIER** (Bonn) explained his method of treating acute inflammation, cellulitis, furunculi, lymphangitis, mastitis, &c., by artificial hyperæmia. The hyperæmia was produced by the application of cupping glasses of different sizes and shapes according to the seat of the affection, so that, for instance, in mastitis large glasses surrounding the entire mamma were employed. When suppuration occurred very small incisions were made and the pus was withdrawn by the suction effect of the cupping glass, which was applied several times a day for five minutes. In lymphangitis and cellulitis of the extremities hyperæmia was produced by the application of a caoutchouc bandage which at first aggravated the inflammatory symptoms and increased the œdema but improvement soon followed. From time to time the bandage must be removed for some hours. Gonorrhœal and pyæmic arthritis were also benefited by the treatment. The details of the procedure were demonstrated on a number of patients from the Berlin University clinic suffering from inflammatory conditions and the same patients were shown at the final meeting of the Congress, when an obvious improvement in the symptoms had occurred.

Suppuration of the Kidney.

Dr. **JORDAN** (Heidelberg) said that he had observed 12 cases of renal and perirenal abscesses as a sequel to furunculi, the cause being hæmatogenic infection. As a rule, only one kidney was affected. The diagnosis was rather difficult, as the symptoms resembled those of appendicitis, enteric fever, and spondylitis. To ascertain the nature of the case pain and enlargement of the kidney and the existence of a place of entrance for the virus were essential. The prognosis was not bad when an early diagnosis was made and nephrotomy was performed; otherwise pyæmic fever might develop.

In the discussion Professor **ISRAEL** (Berlin) said that the point of entrance of the virus might be the mucosa of the nose and that the presence of blood in the urine was essential for the diagnosis.

Appendicitis.

Professor **KOERTE** (Berlin), in introducing a discussion on Appendicitis, said that it was impossible to ascertain the state of the appendix and even to recognise an impending peritonitis without an operation. Of 137 cases of recent origin on which he had operated during the first three days 57 presented the symptoms of peritonitis. Of the patients operated on during the first two days 18 per cent. died and of those on whom the operation was performed on the third day 36 per cent. died. The patients without peritonitis all recovered. By waiting longer than three days the patients were exposed to the danger of pylephlebitis, empyema, pyelitis, and adhesions. The best treatment was the radical operation within the first two days; on or after the third day the abscess should only be opened. After the third day the operation should be postponed till the acute symptoms had subsided. Operations performed during this stage of interval had a mortality of 1 per cent. only. The same procedure was indicated also in cases of appendicitis obliterans.

In the discussion the majority agreed with Professor Koerte. Professor **KUMMELL** (Hamburg), who had formerly advocated a conservative treatment, said that he now preferred an early operation, as the nature of the disease had obviously become more grave. Of 89 cases operated on by him in the early stage only three died.

Dr. **REHN** (Frankfort) said that it was impossible to give a positive opinion as to the prognosis of an acute attack.

Professor **VON HOCHENEGG** (Vienna) directed attention to the formation of abscesses in Douglas's cavity, this occurrence being an early sequel to acute appendicitis.

Professor **SCHLANGE** (Hanover) said that he believed an early operation to be necessary during the first attack; when several attacks had already occurred it was permissible to wait for the interval.

Dr. **FEDERMANN** (Berlin) said that Professor Sonnenburg used to perform an early operation when the case was apparently a severe one. In other cases he waited till the acute symptoms had passed off.

Tetanus Antitoxin.

Professor [illegible] e of a patient w [illegible] tory was wound[illegible] ture of tetanus [illegible] out with a solut[illegible] ight symptoms of tetanus developed. Professor Küster then exposed the axillary and cervical nerves and injected the antitoxin into the nerves. Next day the tetanus contractions had disappeared.

Post-operative Pneumonia.

Dr. **KELLING** (Dresden) said that pneumonia might arise in three ways—namely, by aspiration, by embolism, and by the lymphatic system. Patients who were exposed to cold during the operation were predisposed to an attack of pneumonia. Dr. Kelling believed that there was a direct communication between the lymphatic vessels of the abdomen and those of the thorax.

---

[1] For this report we wish to tender our sincere thanks to the editor of the *Deutsche Medicinische Wochenschrift*, through whose courtesy it has been forwarded to us by our Berlin correspondent.

Dr. **ROTTER** (Berlin) recommended the production of anæsthesia by means of scopolamine and morphine as a means of avoiding pneumonia. This method, moreover, by relieving the pain from which the patients suffered made their respiration deeper and more regular and in this way also tended to prevent pneumonia.

Professor **LENHARTZ** (Hamburg) said that patients showing the first symptoms of pulmonary complications should be made to lie on the healthy side so that the affected lung could admit air more freely.

Professor **KUSTER** said that the use of ether as a general anæsthetic had no influence on the production of pneumonia.

Professor **KRONLEIN** said that he used as little ether as possible and the number of cases of pneumonia in his clinic was decidedly small.

Dr. **MUHSAM** (Berlin) was of opinion that pneumonia after appendicitis was brought about by embolism.

Production of Anæsthesia by Spinal Injections.

Professor **BIER** said that instead of cocaine he now used another compound—namely, stovain, devised by Professor Fourneau, to produce anæsthesia of the lower extremities. The injection should be given in the median line between the first and the second lumbar vertebræ and not until after the escape of the cerebro-spinal fluid. He recommended that no attempt should be made to obtain an extension of the anæsthesia beyond the inguinal region as disagreeable symptoms might be the result. Complications such as headache might be avoided by using isotonic solution and in any case disappeared after the administration of castor oil.

In the discussion the efficacy of Professor Bier's method was generally admitted. Dr. **NEUGEBAUER** said that the best results were obtained by the injection of tropacocaine.

Fractures of the Patella.

Dr. **THIEM** (Cottbus) advocated suture of the fragments in every case where complete coaptation was impossible. He showed by statistical tables that the patients treated in this way recovered within a shorter time and were better able to work than those treated without operation. Subcutaneous sutures should not be used when the fragments were not brought into view; interposed soft tissues were sometimes not removed. Bony union of the fragments could not be obtained by massage.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Small-pox and Small-pox Hospitals in Liverpool, 1902–03, by Dr. R. J. **REECE**.[1]—In this report Dr. Reece gives the results of an elaborate statistical study of the local distribution of small-pox in Liverpool during 1902 and 1903 in relation to the operations of the three hospitals which during different periods in these two epidemic years were used for the isolation of small-pox cases. The inquiry is of special value in its bearings upon the questions of "small-pox hospital influence" and of aerial convection of infection from small-pox hospitals, while the results which have been obtained have important practical applications. The three municipal isolation hospitals in question are respectively those of "Priory-road," "Park Hill," and "Fazakerley." From Dec. 6th, 1901, to the end of 1902 some 552 cases of small-pox occurred in Liverpool. Nearly all of these were isolated in Priory-road hospital which is situated in the north-east of the city. From the beginning of 1903 to the end of June 1585 further cases were known to have occurred. During this period the majority of the cases were isolated in Park Hill hospital, situated to the south of the city, about three miles from Priory-road; others were treated at Fazakerley hospital, outside the city boundary; while a small proportion were taken, as before, into the Priory-road hospital. During the last six months of 1903 the number of new cases of small-pox was 121, nearly all of which were treated at the Fazakerley hospital, admission to the other two hospitals having ceased by the beginning of July. Of these three hospitals Fazakerley alone can be said to be comparatively remote from populous areas and is the only hospital which complies with the population requirements of the Local Government Board. Each of the other hospitals, Priory-road and Park Hill, has a considerable populous area in its neighbourhood, the figures for inhabited houses within a quarter of a mile, within half a mile, and within one mile respectively being for Priory-road 85, 2055, and 21,724; and for Park Hill 171, 2430, and 12,610. The total number of houses in the city of Liverpool is nearly 130,000. The position of the matter in regard to the situation of these hospitals and to the risk of using them during a small-pox epidemic is thus set out by Dr. Reece:—

> The relation of these two hospitals to surrounding population is thus of a kind which is at the present day quite unusual when isolation of small-pox is in question; experience having led to general disuse for small-pox of hospitals having large amount of dwellings in their neighbourhood.
>
> Experience of the sort in question, which is well known, has demonstrated that excessive incidence of small-pox on populous areas in the vicinity of a hospital receiving a plurality of acute cases of the disease is no unusual occurrence and it can hardly be doubted that the relationship between the operations of these hospitals and the excessive small-pox incidence in their neighbourhood is one of cause and effect. Further, it has been strongly indicated from careful study of various instances of "small-pox hospital influence" that explanation of extra incidence of small-pox around such hospital, by assumption of hospital mismanagement or of lack of precautions in regulating the necessary traffic and business of the establishment, does not suffice to account for the facts. The generally accepted and, so far as I am aware, the only completely satisfactory explanation of the peculiarities of small pox incidence around hospitals receiving acute cases of the disease is dissemination of infection by aerial convection; an explanation introduced many years ago by Mr. W. H. Power, the Board's present medical officer, after detailed study of the behaviour of small pox around Fulham and other London hospitals. He held that particulate matter capable of conveying infection, escaping into the air from the wards of a small-pox hospital, does on occasion and in suitable atmospheric conditions become wafted to considerable distances from such hospital. "Hospital influence" in this sense has been traced in certain instances, where circumstances allowed the study to be made in respect of inhabited areas, as far as one mile from the hospital; by some observers it has been thought to have been traceable, though to a much less degree, on inhabited areas situated even further than a mile from the hospital. It has not, of course, been affirmed that, whenever acute cases are admitted to a small pox hospital situated near a populous area, demonstration of aerial convection will certainly be forthcoming if only the facts be strictly studied. There is ground, indeed, for belief that a small-pox hospital in a populous area does not as a result of its actual operations *always*, whether aerially or otherwise, distribute small-pox in conspicuous fashion in its neighbourhood; and perhaps opinion has come to be entertained in some quarters that disadvantage such as accrued from Fulham and other small-pox hospitals may be regarded as the exception, not the rule. Similarly there has, when emergency has resulted in compulsory use as it were for sma[illegible] neighbourhood, arisen a tendency to [illegible] be alleged to be due to the hospital. A demonstration, therefore, of absence of spread of small-pox from hospital in the case of *Liverpool*, where three hospitals, two of them in the city, were receiving acute small-pox cases and where in particular one of the hospitals (Park Hill) for a period of some 24 weeks at the height of the epidemic received acute small-pox patients in large numbers, would, if established, be not only particularly interesting to epidemiologists but in its administrative aspects would be reassuring to small-pox hospital authorities.

The labour devoted to this inquiry by Dr. Reece and by the officials of the Liverpool corporation who assisted him in ascertaining the facts must have been enormous. The local distribution of small-pox in Liverpool is shown in this report by a series of tables and diagrams, while a set of 23 "spot maps" is supplied which show the position of each house newly invaded by small-pox during each fortnight of the two years in question. With these aids Dr. Reece has succeeded in giving a concise account of the subject in the small compass of 15 pages which should be read by all interested in the question; they are themselves too condensed to admit of any adequate abstract. The result, as regards "hospital influence," is certainly striking. During 1902, when Priory-road hospital sufficed for all the cases of small-pox the proportion of houses invaded by small-pox in the whole of Liverpool, more than a mile from that hospital (including the neighbourhoods of Park Hill and Fazakerley hospitals), was 1·6 per 1000; within a mile of Priory-road hospital the corresponding rate was 2·7; within three quarters of a mile, 3·3; and within half a mile, 6·8. The next period, Dec. 7th, 1902, to June 20th, 1903, was one of full activity at all three hospitals. Houses in Liverpool more than a mile from any one of these hospitals during these months were invaded by small-pox at the rate of 8·6 per 1000; those within a mile of any one of these hospitals were invaded at the rate of 11·5; within half a mile at the rate of 22·2; and within a quarter of a mile at the rate of 41·5 per 1000. Dr. Reece gives tables showing for each hospital the invasion-rate respectively of houses distant 0-¼ mile, ¼-½ mile, ½-¾ mile, and ¾-1 mile from the hospital. For each hospital there are clear indications of the graduation in incidence which is so conspicuous a feature of "small-pox hospital influence." The details given in Dr. Reece's tables show that in the case of Park Hill, a large hospital receiving many cases at the height of an epidemic, the excessive incidence of small-pox on the surrounding neighbourhood was very remarkable and persistent. It commenced some six weeks after the hospital had begun to receive cases of small-pox and it continued until the hospital was finally closed for small-pox. Dr. Reece concludes that:—

---

[1] London, Wyman and Sons, Fetter-lane; Edinburgh, Oliver and Boyd; Dublin, E. Ponsonby. Price 2*s.* 6*d.*

1. Inhabited areas within a mile of each of the three Liverpool small-pox hospitals have suffered more severely from small-pox than the city

Fazakerley hospital, situated practically in the country and with comparatively few houses within a mile of it, appears to have caused an excess of small-pox in its neighbourhood, which, in its degree, was as severe as that which was caused by the other two hospitals in the city. This is a noteworthy point, although, as Dr. Reece points out, too much stress must not be laid upon invasion-rates in this instance, as they are necessarily derived from small figures. Another interesting indication of this inquiry is that the small hospital of Priory-road appears to have influenced the rate of invasion of houses in its neighbourhood to a smaller extent relatively than the larger hospitals of Park Hill and Fazakerley. The whole circumstances of these occurrences, so closely parallel to those met with in other outbreaks round small-pox hospitals situated in populous neighbourhoods, tend to support the presumption that the exceptional prevalence of the disease round the hospitals has been due, as Mr. Power suggested long ago, to infection having from time to time been carried by means of local air currents in suitable states of the atmosphere from the hospital to houses in its vicinity. It is hardly possible to frame a theory of personal infection, implying, among other things, continuous bad administration at each of the hospitals in question, which would sufficiently explain the facts. And it may almost be assumed that in Liverpool, with its excellent organisation to deal with infectious diseases, the risk of spread of small-pox by means of carelessness of hospital staff or negligence on the part of those concerned in ambulance or disinfection work must have been greatly minimised, if it was not absent altogether. Dr. Reece gives ample testimony in his report to the general excellence of the system adopted in these directions under the able administration of Dr. E. W. Hope, the medical officer of health of the city.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8827 births and 4300 deaths were registered during the week ending May 20th. The annual rate of mortality in these towns, which had been 16·5, 15·4, and 15·0 per 1000 in the three preceding weeks, further declined last week to 14·4 per 1000. In London the death-rate was 14·1 per 1000, while it averaged 14·5 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·0 in King's Norton, 7·3 in Wolverhampton, 7·4 in Hornsey, 7·8 in Barrow-in-Furness, 8·7 in Rotherham, and 8·9 in East Ham and in Norwich; the highest rates were 19·2 in Rhondda, 19·8 in Merthyr Tydfil, 25·1 in West Bromwich, 24·4 in Tynemouth, 22·5 in Preston, and 26·0 in Middlesbrough. The 4300 deaths in these towns included 442 which were referred to the principal infectious diseases, against 460, 469, and 401 in the three preceding weeks; of these 442 deaths, 172 resulted from measles, 129 from whooping-cough, 50 from diarrhœa, 43 from scarlet fever, 29 from diphtheria, 18 from "fever" (principally enteric), and one from small-pox. In Hornsey, Hastings, Bournemouth, King's Norton, Bolton, Rochdale, Swansea, and in six other smaller towns no death from any of the principal infectious diseases was registered; whilethe highest death-rates from these diseases occurred in Leyton, West Bromwich, Smethwick, Coventry, Warrington, and Sheffield. The greatest proportional mortality from measles was recorded in West Bromwich, Smethwick, Coventry, Wigan, Warrington, Sheffield, Rhondda, and Merthyr Tydfil; from whooping-cough in Willesden, Tottenham, Leyton, Smethwick, Aston Manor, Preston, South Shields, Tynemouth, and Newport (Mon.); and from diarrhœa in West Ham, West Bromwich, and Grimsby. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns. One fatal case of small-pox was registered in London but none in any other of the large towns. The number of small-pox cases under treatment in the Metropolitan Asylums Hospitals, which had been 17 at the end of each of the two preceding weeks, had declined to 15 at the end of last week; three new cases were admitted during the week, against four, four, and two in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2182, 2152, and 2177 on the three preceding Saturdays, had further risen to 2211 on Saturday last, May 20th; 319 new cases were admitted during the week, against 255, 235, and 319 in the three preceding Saturdays. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 306, 256, and 251 in the three preceding weeks, further declined to 226 last week, but were 16 above the number in the corresponding period of last year. The causes of 49, or 1·1 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Leeds, Hull, Newcastle-on-Tyne, and in 44 other smaller towns; the greatest proportions of uncertified deaths occurred in Birmingham, Coventry, Rochdale, Blackburn, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·8, 18·0, and 19·5 per 1000 in the three preceding weeks, declined again to 16·7 per 1000 during the week ending May 20th but was 2·3 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 8·9 in Greenock and 10·7 in Perth to 17·2 in Dundee and 19·4 in Glasgow. The 560 deaths in these towns last week included 26 which were referred to measles, 25 to whooping-cough, 19 to diarrhœa, three to diphtheria, two to "fever," and one to scarlet fever, but not any to small-pox. In all 76 deaths resulted from these principal infectious diseases last week, against 59, 67, and 83 in the three preceding weeks. These 76 deaths were equal to an annual rate of 2·3 per 1000, which was 0·8 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 21, 16, and 32 in the three preceding weeks, declined again last week to 26, of which 21 were registered in Glasgow and five in Edinburgh. The deaths from whooping-cough, which had been 27, 26, and 30 in the three preceding weeks, decreased to 25 last week, and included 18 in Glasgow, two in Dundee, two in Paisley, and two in Greenock. The fatal cases of diarrhœa, which had been eight, 15, and nine in the three preceding weeks, rose again last week to 19, of which 11 were registered in Glasgow, three in Aberdeen, two in Edinburgh, and two in Dundee. The deaths from diphtheria, which had been four and six in the two preceding weeks, declined again to three last week and included two in Edinburgh. The two fatal cases of "fever" occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 121, 132, and 108 in the three preceding weeks, further declined last week to 83, and were 14 below the number in the corresponding period of last year. The causes of 16, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·9, 22·0, and 23·7 per 1000 in the three preceding weeks, declined again to 19·5 per 1000 during the week ending May 20th. During the past four weeks the death-rate has averaged 21·8 per 1000, the rates during the same period being 14·8 in London and 17·1 in Edinburgh. The 142 deaths of persons belonging to Dublin registered during the week under notice were 30 below the number in the preceding week and included six which were referred to the principal infectious diseases, against eight in each of the three preceding weeks; of these, three resulted from diarrhœa, two from measles, and one from whooping-cough, but not any from small-pox, scarlet fever, diphtheria, or "fever." These six deaths were equal to an annual rate of 0·8 per 1000, the death-rates last week from the principal infectious diseases being 1·3 in London and 1·9 in Edinburgh. The three fatal cases of diarrhœa corresponded with the number in the preceding week; and the deaths from whooping-cough, which had been two, three, and four in the three preceding weeks, declined again last week to two. The 142 deaths in Dublin last week included 36 of children under one year of age and 38 of persons aged 60 years and upwards; the deaths of infants considerably exceeded the number in the preceding week, while those of elderly persons showed a marked decline. Four inquest cases and five deaths from violence were registered; and 48, or more than a third, of the deaths occurred in public institutions. The causes of ten, or more than 7 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: E. C. Ward to the *Carnarvon* and H. E. South to the *Emerald* (to date May 25th).

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned gentlemen have been appointed Officers, viz.:—Henry Reah to be Surgeon (dated May 15th, 1905) and George Robert Harland to be Surgeon (dated May 17th, 1905).

ROYAL ARMY MEDICAL CORPS.

Major F. J. Wade-Brown, from Gosport, and Captain H. O. B. Browne Mason, from India, are appointed to the London District for duty, and Lieutenant-Colonel F. J. Lambkin is appointed for duty to the London Military District. Major McCormack, retired pay, assumes medical charge of troops and Military Hospital, Omagh. Colonel R. H. Quill, who has been promoted to Surgeon-General, is appointed Principal Medical Officer at Netley.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Captain (Captain, Army Medical Reserve of Officers) T. F. Devane resigns his commission (dated May 24th, 1905). 4th Volunteer Battalion the Royal Fusiliers (City of London Regiment): Henry Macnaughton Macnaughton-Jones (late Surgeon-Lieutenant, 1st Middlesex Royal Engineers (Volunteers)), to be Surgeon-Captain, and is borne as Supernumerary whilst commanding the Bearer Company of the 1st London Volunteer Infantry Brigade (dated April 22nd, 1905). 1st Volunteer Battalion the Suffolk Regiment: Supernumerary Surgeon-Lieutenant-Colonel G. S. Elliston (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Harwich Volunteer Infantry Brigade) is granted the honorary rank of Surgeon-Colonel (dated May 19th, 1905). 4th (Hunts) Volunteer Battalion the Bedfordshire Regiment: Charles Archibald Lees (formerly Captain) to be Surgeon-Lieutenant (dated May 19th, 1905). 4th Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant-Colonel S. B. Mason is granted the honorary rank of Surgeon-Colonel (dated May 19th, 1905). 3rd Lanarkshire: John Wilson Leitch to be Surgeon-Lieutenant (dated May 19th, 1905). 22nd Middlesex (Central London Rangers): William Lloyd to be Surgeon-Lieutenant dated April 17th, 1905).

THE SHORTAGE OF OFFICERS FOR THE ARMY.

Public attention has been directed by the press of this country to the declining supply of candidates for commissions in the army, which is said to be engaging the serious attention of the War Office at the present time. The *Standard* of May 11th had a leading article on the subject which apparently went to the main roots of the matter—namely, that while, on the one hand, the army, now that it has become a hard-worked and irksome profession, has ceased to draw the more moneyed class of young men who have hitherto been attracted to it as on the whole an adventurous and pleasant life with the chance of seeing active service and of distinguishing themselves in the field; it has, on the other hand, but little to offer in the way of present income and future prospects to those of smaller means whose ambition it is in joining the army to make it truly their calling in life. To such and to their parents it does not, in the language of the day, seem "good enough" when compared with other professions and callings. And to all alike there are the "uncertainty of tenure" and prospects and the loss of confidence engendered by the frequent changes that have taken place of late years. That patriotism, the warlike spirit, and love of adventure are as strong as ever is proved by the fact that there is never any lack of volunteers for field service in time of war. But there is one thing which has been omitted and must be added to these reasons for it has a very important bearing. It is the disheartening effect of the growing tone of disparagement or even of imputed blame in which the services of the "regulars" seem to be nowadays regarded in almost every campaign. Officers of the Army Medical Service can speak feelingly on this subject, for by way of recompensing them for all their labours at the end perhaps of an arduous campaign they have had to vindicate their corps before some War Office committee or other. It seems to be altogether forgotten that they could only use the hospital material placed at their service and conform to the official regulations in force. In these respects their department was on an altogether different plane from that occupied by voluntary aid societies. And in the case of the troops of the regular army the officers had often to encounter, as in the case of the South African war, much hardship and risk of life in carrying out perhaps the orders of some possibly incompetent general only to find themselves at the end of the war characterised as "stupid" or as after all "unprofitable servants."

EMPIRE DAY: THE ROYAL ARMY MEDICAL CORPS WAR MEMORIAL.

May 24th, the anniversary of the birth of Queen Victoria, now known as Empire Day, was celebrated with much enthusiasm throughout the kingdom. The King at Aldershot witnessed a sham fight on Frensham Common and subsequently unveiled a memorial to members of the Royal Army Medical Corps who gave their lives for the cause of their country in the South African campaign. At St. Paul's Cathedral the Prince of Wales unveiled a memorial to the colonial troops who fell in the same war. The memorial to the Royal Army Medical Corps is built of granite and bronze panels bear the name of every man who died during the war in South Africa. An inscription reads: "To those who gave their lives for their country." We hope to refer more fully to the ceremony in a subsequent issue.

DEATHS IN THE SERVICES.

Colonel Henry Comerford, R.A.M.C. (retired), recently, aged 61 years, at Charing Cross Hospital, where he had been removed from the Craven Hotel, Craven-street, Strand. He entered the service as assistant surgeon in 1866, was promoted to surgeon in 1873, surgeon-major in 1878, surgeon-major ranking as lieutenant-colonel in 1886, brigade-surgeon in 1892, and colonel in 1896, retiring in 1902. He served in the Zulu campaign of 1879 and took part in the battle of Ulundi (medal and clasp), and also in the late Transvaal campaign, when he was present at the defence of Pretoria (mentioned in despatches).

Lieutenant-Colonel C. B. Hill, R.A.M.C., on May 7th, at Guy's Hospital, aged 50 years. He entered the service as a surgeon in 1880, was promoted surgeon-major in 1892, and lieutenant-colonel in 1900. He took part in the Waziri Expedition in 1881.

THE VISIT OF BRITISH MEDICAL MEN TO PARIS.

The military hospitals in Paris were visited by Surgeon-General A. H. Keogh, C.B., Director-General of the Army Medical Service, by Lieutenant-Colonel M. W. H. Russell, Deputy Assistant Director-General of the Army Medical Service, and by Lieutenant-Colonel B. M. Skinner, Secretary to the Army Medical Advisory Board. These gentlemen were personally conducted by Dr. Strauss, the Inspector-General of the French military hospitals.

THE WAR IN THE FAR EAST.

There has been heavy rain following a dust storm in Manchuria, rendering the roads bad and impeding transport. There are signs of extensive movements of Marshal Oyama's forces and skirmishes are reported by both sides. In these the casualties seem on the whole to preponderate on the side of the Russians and are gradually mounting up. The deaths from disease in their army since the war began must have reached a heavy total as compared with those in the Japanese armies. Notwithstanding that the next battle threatens to take place between the hostile armies public interest and speculation have been transferred from the land forces to the fleets in consequence of its being universally recognised how much hinges upon the results of the impending operations at sea. It will obviously be of the greatest interest and importance to the naval powers generally to see what arrangements are made for the disposal of the sick and the wounded in the event of the occurrence of any naval engagement.

According to the *Novosti*, Professor D. O. Ott has been ordered to join the acting Russian army for four months. His special mission is to investigate the nature of medical organisation in the army.

Correspondence.

"Audi alteram partem."

DIABETES AND THE THYROID GLAND.

To the Editors of THE LANCET.

SIRS,—In his very instructive Goulstonian lecture on Diabetes Mellitus, published in THE LANCET of April 22nd, p. 1053, Dr. W. C. Bosanquet says: "Lorand states that it is chiefly in female diabetics that actual enlargement of the thyroid is present; though why the other sex should not also exhibit the same alteration is not clear." May I be allowed to make a few remarks on the subject? According to George Murray, the thyroid of women is bigger than that of men. I do not think it improbable that this may be in connexion with the fact that there exist very intimate relations between the ovaries and the thyroid, demonstrated clearly by the frequency of the swelling of the thyroid in consequence of defloration, conception, during puberty, menstruation, pregnancy, lactation, and the climacterium (menopause). Thus the female thyroid is more exposed to hyperfunction than the male one, and this might also be the cause of the greater frequency of goitre, of Graves's disease, and of myxœdema in women. I should also like to add that the median lobe of the thyroid is in the great majority of cases more developed in women than in men; its swelling can thus be easier seen and felt than that of the lateral lobes which are more covered by musculature.

It is certainly not easy to judge the condition of a thyroid by its external appearance. Sometimes a thyroid may not be seen or felt and still there might be at the necropsy a very big thyroid. As generally accepted Graves's disease is a condition of hyperthyroidia (hyperactivity of the thyroid) and still there are not so rarely cases of Graves's disease where no big thyroid can be seen or felt. On the other hand, the big size of the cretin's thyroid is no proof of its good working condition. Hence the only reliable proof of the functional activity of the thyroid as of other glands can be gained merely by its histological examination. As I stated in my paper before the London Pathological Society on Feb. 21st last I have found in the thyroid of four diabetic dogs alterations that resembled those found by Chalmers Watson[1] in fowls fed for a certain time only on animal food.

May I also be allowed to say a word on the rarity of diabetes in myxœdema? As Dr. Pavy has stated in his discussion with me in the Pathological Society he has never seen a case of myxœdema with diabetes; and in the description of the three cases of the Philadelphia County Medical Society which he kindly lent me, the author himself admits that two cases were not pronounced "and the third case was irregular." After having looked through the literature on the subject I have only found two cases of myxœdema with diabetes, those of Ewald[2] and Béclère.[3] In both cases diabetes had been the consequence of thyroid medication in big doses.

I am, Sirs, yours faithfully,

Carlsbad, May 15th, 1905. DR. ARNOLD LORAND.

TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—May I, through the medium of your widely read journal, thank the many medical Freemasons and others who sent me their votes for the medical candidates at the recent elections of the different Masonic charitable institutions? The success of these candidates is largely due to the hearty response to my appeal in THE LANCET of March 25th and must be very gratifying to those who were interested in the cases. The results are as follows:—

55 .—Eileen Torrens, successful with
uccessful.
—Charles Hughes, successful with 5309 votes, Alfred Burns, successful with 3709 votes; Cyril Hockley unsuccessful.

Royal Mason Benevolent Institution.—Joseph Rickets, successful with 3602 votes, Elinor Gartley, successful with 3855.

I am, Sirs, yours faithfully,
HAROLD S. SINGTON,
Secretary, St. Luke's Medical Lodge of Instruction.
44, St. Mary's Mansions, W., May 22nd, 1905.

THE FINANCIAL RELATIONS OF THE LONDON HOSPITALS AND THEIR MEDICAL SCHOOLS.

To the Editors of THE LANCET.

SIRS,—In a leading article in THE LANCET of May 20th, p. 1362, in which reference is made to the arrangement that has been come to between the Westminster Hospital Medical School and King's College for the teaching of the preliminary and intermediate subjects of the curriculum at the latter institution, it is stated that the arrangement has been made with King's College *Medical School*, and not as should have been said with the *Science Department* of King's College, which has no necessary connexion with the Medical School.

A PLEA FOR THE RECOGNITION OF THE TREATMENT OF DISEASE BY INTRAVENOUS INJECTIONS.

To the Editors of THE LANCET.

SIRS,—In the report of the discussion on the above subject at the meeting of the Edinburgh Medico-Chirurgical Society held on May 3rd—1. It was not a *single* but *six* injections of a 1 in 2000 solution of CH_2O in physiological solution which affected the temperature in the case of oral sepsis. It brought it down from 104·5° to normal in nine days. Each injection was 110 cubic centimetres. 2. While the tuberculous abscess was quite cured as reported the patient some months later broke down and died from a practically general tuberculosis. Had she remained well permanently the power of arresting recent acute tubercle with CH_2O intravenously would have been phenomenal. Still the immediate success in this case with "Maguire's" solution was brilliant. 3. I am also reported as having said that the presence of apical scars or caseous nodules was not proof of the curability of *pulmonary tuberculosis.* The term I used was *phthisis* not pulmonary tuberculosis, and I further explained my meaning by stating that I referred to the condition after the necrotic process has begun and *phthisis* is a clinical entity. These points are of some importance and I trust that you will be good enough to give space to them.

FIFTH ANNUAL SOUTH AFRICAN CIVIL SURGEONS' DINNER.

To the Editors of THE LANCET.

SIRS,—Through the medium of your journal we should like to call attention to the above dinner, which will take place on Tuesday, July 4th, at 8 o'clock, at the Imperial Restaurant, Regent-street. Mr. W. Watson Cheyne, C.B., has kindly consented to take the chair. Reply cards will be sent to those whose addresses are available and we hope that those who wish to attend will reply as soon as possible. The price of the dinner will be 10*s.* 6*d.* (exclusive of wine).

We are, Sirs, yours faithfully,

C. GORDON WATSON, } Secretaries.

44, Welbeck-street, W., May 24th, 1905.

UNPAID AS USUAL!

To the Editors of THE LANCET.

SIRS,—I received a few days ago a letter from the senior medical officer of the volunteer infantry brigade to which I belong. I inclose a copy of it.

> A number of volunteer medical officers will be required for duty in the station hospitals of the regular army during the training season (May to August) Those officers would not, *of course* (the italics are mine), receive pay nor would any expense to the public be admissible, hence their attendance must be entirely voluntary. Should you be willing, &c.

Comment is, perhaps, superfluous, but one cannot help observing what an encouragement such a proposal must be to the volunteers to perfect themselves as a reserve to the regular forces. Do our colleagues in the Royal Army Medical Corps serve during the training season without pay and with no expense to the public?

That such an offer can be seriously made to qualified medical men with, presumably, some idea of a more or less favourable response points to the urgent necessity of some strong professional combination, while the fact that the War Office considers it probable or even possible that commissioned officers of the auxiliary forces may be willing to perform public duties without any expense to the public, but at a considerable loss to themselves, and alongside officers of the regulars and militia who are drawing full rates of pay and allowances for the performance of the same duties, only indicates the utter futility of any hope of any improved position for the volunteer or any practical recognition of him as a genuine factor in any scheme of national defence. It is to be devoutly hoped that volunteer medical officers with any respect for their profession or for the force to which they belong will have nothing to do with this proposal. I am, Sirs, yours faithfully,

May 20th, 1905. A. M. R.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Physique of Salford Children.

Mr. C. H. Tattersall, the medical officer of health of Salford, and the assistant medical officer, Dr. J. J. Butterworth, give interesting reports on the medical work done by them in 1904 for the Salford education committee. There are 4000 children in Salford attending school who are under five years of age and Mr. Tattersall agrees with many others who have studied the question that the attendance of these children should be discouraged, believing that "the sixth year is early enough for a child to attend school." There is considerable difference in the social condition of the neighbourhoods in which the six schools selected for observation are situated and the schools differ considerably also. 1. Boys chiefly from the class of clerks, warehousemen, and shop keepers. The boys are clean, well nourished, and sufficiently clothed. The school is surrounded by a large open space and has a very large playground. 2. Boys chiefly the sons of unskilled labourers. Clothing is deficient both in quality and quantity, not one boy wearing an under-vest. Vermin are very prevalent. 3. Boys from the skilled artisan class and latterly a good many children of dock labourers. The neighbourhood has of late become thickly populated. 4. Scholars chiefly from the skilled artisan and clerk class. They are well dressed and nourished, each boy wearing two garments, an under-vest and shirt. The school is close to a large park. 5. Here the boys are chiefly the sons of mill-workers. They are well but roughly clothed and well nourished. There is a large playing field attached to the school. 6. This school is situated in what is still regarded, in spite of some improvement in late years, as the worst district in Salford. It is, as one would expect, densely populated. In these six schools, three of a better and three of a poorer class, records were taken of the height, weight, and chest girth of all the boys between the ages of seven years and nine months and eight years and three months, between nine years and nine months and ten years and three months, and between 12 years and nine months and 13 years and three months. This gave three age periods approximately of eight, ten, and 13 years. As would be expected, in the three higher class schools—i.e., in those where the social conditions and the surroundings are comparatively more favourable for healthy existence—the physique is better than in the three poor schools. At the age of eight years all are fairly equal, but at 13 years there are marked differences. As showing that something more than mere social condition affects the result there is a seeming exception in the case of No. 5 school which stands at the top of the list as to physique, although the boys are roughly clothed children of mill-workers. They are, however, well fed and "attached to the school is a large playing-field" in an open situation. This appears the chief factor likely to account for the better growth and development of the No. 5 boys, who at 13 years of age are two and a third inches taller and 13 pounds heavier than those of No. 3 school, the latter being chiefly the sons of skilled artisans. Over those of No. 6 school they have the advantage of being nearly four inches taller and about 14 pounds heavier. As these boys will most of them earn their living by bodily work the advantage at the start should always keep them in front of those less favoured. In accounting for the marked superiority of the boys in No. 5 school it may be mentioned that the district is one where the social and moral tone is somewhat above the average. "More than 90 per cent. of the children attend Sunday school," the people keep early hours, and "the children are abed betimes." As Mr. Tattersall says, improper feeding and under-feeding have marked consequences; where the people are poor and the children are badly fed the physique shows the natural result. On the other hand, he does not blame the mothers for want of care of their young children and he finds that more than 90 per cent. of these have been breast-fed. These working class mothers set a good example to those in more comfortable positions. There has been of late considerable improvement in this respect, for three or four years ago only 70 per cent. of these Salford mothers fed their children from the breast. He advocates "breast-feeding and teetotalism on the part of the mothers." Some of the schools are well provided with facilities for out-door play but others are not. No. 6 school, where the children are "dirty, badly clothed, and ill-nourished" and where "a large proportion showed distinct signs of rickets," is situated in Greengate, the worst district in Salford and has none of these advantages close at hand, and the children would rather play in a dirty crowded slum near home than in a park at a distance. Now that attention is so much directed to this question it is to be hoped that sensible measures will be taken to improve as much as possible the evil influences of our manufacturing towns on the physique of their inhabitants. It is a matter of the gravest import to the future of our race and it will be a sorry result of our civilisation if "men decay." Although there are some encouraging facts it is not cheering, to quote the words of a careful observer, that "the average of child physique is lower in Salford than in any town in Great Britain of which record has been taken, with the possible exception of Rochdale." Our sanitarians have plenty of work before them in the improvement of hygienic conditions, while our moral sanitarians have a harder and, perhaps, more important task still in helping the people to understand and to live a higher life physically than the groveller in the slums ever dreams of.

The Black Smoke Nuisance.

It is a very common thing for manufacturers to be fined for allowing black smoke to be sent out from their chimneys and they often pay the fines gladly rather than adopt the means necessary to abate the nuisance. But it is not so common for the sanitary department of the Manchester corporation to summon the electricity department, that one of all others that was to do away with black smoke and to convert Manchester from what it is to a place of sweetness and light. This department, however, has a tall chimney which recently emitted black smoke to such a degree as to render a summons necessary. The resident engineer said that it was caused by certain experiments. Perhaps he might vary the experiments a little and try to make some with the object of lessening, and not increasing, the production of smoke. An order to abate in 28 days was made so that there is time for some fresh experiments.

Oswaldtwistle's Low Birth-rate.

Low birth-rates are becoming so general as to increase the seriousness of the nation's outlook. Dr. A. E. Townley, the medical officer of health, states that during the past year the birth-rate of Oswaldtwistle was 21·91 per 1000, compared with 28 87, the average for the last ten years. He complains also that the smoke nuisance has an effect on the number of deaths from bronchitis. The infantile death-rate was 191 per 1000, the highest, with two exceptions, for the last ten years. It is difficult to imagine the manufacturing districts of Lancashire free from the defilement of black smoke, but what a much happier and healthier land it would be with its streams clean and its vegetation and beauty restored.

Duck Pond or Plunge Bath?

It is reported that in Milnshaw Gardens, Accrington, there is a piece of water which was originally intended for, and used as, an open-air plunge bath but is now called a duck pond. This suggests a habitat where the larvæ of gnats luxuriate but there is no intimation of the presence of the pernicious anopheles. However this may be, there seems to be full justification for the recommendation to the town council "to clean out its duck pond in Milnshaw Gardens and restore it to its original use as an open-air plunge bath." Town councils, whether Progressive or Moderate, have to be reminded occasionally that some simple sanitary measures are as desirable in English boroughs as in West African swamps and it is well worth some little trouble to lessen the swarms of our English gnats which are often a great nuisance and in days gone by caused widespread sickness, from the danger of which we are not altogether free.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

A New Inebriate Reformatory.

UNDER the conditions of the Act of 1898 a certified inebriate reformatory has just been opened at Cattall, which is situated about midway between York and Harrogate and where an excellent site of about 50 acres in an elevated situation has been secured. The cost of the undertaking will, it is expected, amount to about £50,000, which includes the sum of £4750 paid for the land. As the joint committee charged with the undertaking is representative of the county councils of the three Ridings and the councils of the county boroughs of Bradford, Halifax, Hull, Leeds, and York, it is calculated that it will only require a rate of $\frac{3}{7}$th of a penny in the £ to meet the payment of the £2550 required for interest and sinking fund charges on a thirty years' loan. The expenses of maintenance will, after the first 12 months, be met by the separate authorities in proportion to the number of inebriates committed from their areas. Accommodation has in the first instance been provided for 80 inebriates, but the central administration block has been made large enough to meet an increase to 300. The accommodation takes the form of detached cottage homes each providing for 20 cases in two groups of ten each. A separate bedroom is provided for each inebriate. Three of the cottages are to be devoted to women and the fourth will provide accommodation for 20 men. Lord Wenlock, in declaring the institution open, pointed out that there were three different kinds of institutions for dealing with inebriates. These were the inebriate retreats of the Act of 1879, the State inebriate reformatories, and the certified inebriate reformatories, of which that which he had declared open was an example. It was intended for the reception of those who, being habitual drunkards, had been convicted of crime, either when they were under the influence of drink or where drink was found to have been a contributory factor, as well as for those who had in one year been convicted four times of certain offences of drunkenness. The institution is of course intended for reformation treatment and a circular has been issued by the comn[illegible] in these terms: "If for the [illegible] nly commit in proper cases, a [illegible] mit when necessary, some approach towards proving the utility of the institution may be made; but if judicial authorities hesitate because the percentage of good results is at present small, especially amongst the early cases which they may send, then a necessary work will be hindered."

May 23rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Officer of Health of Chipping Sodbury.

THE circumstances attending the election of a local practitioner as medical officer of health of the rural district of Chipping Sodbury, near Bristol, in succession to Dr. Francis T. Bond, who has held the position for 32 years, have already been related in THE LANCET.[1] At a meeting of the district council held on May 17th a letter was read from the Local Government Board regretting the withdrawal of the district from the combination which had for many years elected a joint medical officer of health and stating that the Board was anxious that the situation should be discussed by representatives of the various districts concerned and had accordingly asked the clerk to the Gloucester district council to call a meeting of such representatives. The district council decided not to send any representatives to the conference and adopted the following motion:—

> [illegible] forthwith call upon the Local Government Board to sanction the appointment of our nominee.

At a meeting of the Gloucestershire branch of the British Medical Association held at Gloucester on May 18th it was resolved:—

> That it is desirable in the interests of the medical profession generally that in any locality in which an attempt is made by any public or other organised body to treat their medical officers or employés with injustice the local members of the profession should loyally combine to support their menaced brethren.

And a further resolution was also carried unanimously, on the proposition of Dr. J. Middleton Martin and Dr. G. B. Ferguson, instructing the branch representatives to urge upon the council of the Association the necessity for pressing on the Public Health Bill giving fixity of tenure to medical officers of health.

Death from Lead Poisoning.

Deaths from lead poisoning contracted during industrial pursuits are of sufficient rarity to merit notice. A man, 36 years of age, died from this cause in Bristol on May 1st. He was a silver refiner and was engaged in extracting silver from lead. He had been employed for many years at the same work and in 1899 had an attack of lead colic. Epileptic convulsions were the most prominent symptoms immediately preceding death. Sufficient washing accommodation as required by the special rules relating to dangerous trades appears to have been provided at the works in which the deceased man was employed and he is said to have been of cleanly habits.

University College, Bristol.

Nearly 1500 persons were the guests of the council and staff of University College, Bristol, in the new College buildings on the occasion of the triennial conversazione on May 19th. Professor Stanley Kent during the evening made a series of experiments illustrating the fatigue of muscles, pulse tracings, colour blindness, and finger prints. Demonstrations of the process of making liquid air were given by

---

[1] T[illegible]NCET, April 15th (p. 1035) and 29th (p. 1146), 1905.

Professor Travers who also explained the working of the hydrogen liquefier. In the chemical laboratory there was an exhibition of minerals, alkaloids, drugs, and artificial colouring matters and there was elsewhere a large collection of modern scientific apparatus.

The Medical Officer of Health of Gloucester.

Mr. W. More Hope, who was recently elected medical officer of health of the city of Gloucester, was appointed without reference to any specified period and the Local Government Board has now sanctioned his appointment in the first instance for one year and provided the city council at the end of the year still desires it the Board will sanction the permanent appointment.

Taunton Isolation Hospital.

The Taunton isolation hospital is under the dual control of the Taunton town council and the Taunton rural district council. Recently this arrangement does not seem to have worked very satisfactorily and Dr. H. J. Alford, the medical officer to the hospital, tendered his resignation. At the meeting of the Taunton town council held on May 17th the matter came under discussion and eventually the following motion was carried:—

> That this council express their sympathy with Dr. Alford on the treatment which has led to his resignation and decide not to accept it. That the council considers the dual control of the hospital is not working satisfactorily and authorise their committee to bring up a report as to the expediency of the council taking over the sole ownership and management of the institution.

May 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Free Food for School Children.

IN connexion with the Education Bill for Scotland at present before Parliament considerable discussion has taken place among those interested on the subject of free food for school children. At a conference in Glasgow held under the auspices of the committee of the Queen Margaret Settlement and the Charity Organisation Society a letter was read from the medical officer of health of Glasgow in which he said that one of the most interesting revelations of the present school inquiry was that the fatherless child in one-apartment families was better cared for—i.e., better clothed, better fed, and cleaner—than the one-apartment child whose father was alive. This seemed to him to emphasise the need for the feeding of children on a much larger scale than had hitherto been attempted. If the figures obtained in the inquiry had any significance it lay in the suggestion that the underfed child was educationally on a low level and was likely to become industrially inefficient in later years. The Glasgow trades council, in discussing the same question, by a large majority supported a resolution in favour of the feeding of all school children, the argument urged in favour of this proposal being that if only a section of the children received food it would cast a stigma upon that section.

The Treatment of Glanders.

Representatives of the Glasgow corporation and the Lanarkshire county council recently interviewed the President of the Board of Agriculture on the subject of glanders among horses and the methods of preventing the disease. It was urged that a new order should be issued at once conferring additional powers on local authorities to deal with outbreaks. Glasgow and Lanarkshire, like the local authority of London, desire the compulsory application of the mallein test Numerous experiments in Glasgow seem to have supported the views of those who have faith in the curative action of mallein. Another matter dwelt on was the desirability of fixing on the Imperial Exchequer the expense involved in the slaughter of animals not clinically affected. It was claimed by the deputation that the disease could be cured and that horses could be permitted to work during the period of reaction with the mallein test.

Juvenile Smoking.

The magistrates' committee of the Glasgow corporation has again been considering the question of juvenile smoking. The suggestion was discussed of making it an offence for a boy under the age of 16 years to be found using tobacco or having it in his possession for his own use. The school board has taken the initiative in issuing an appeal to householders to discourage energetically the evil practice of juvenile smoking.

Glasgow Dental Hospital.

The annual report shows that this hospital is fortunate in having a deficit of only £3 18*s.* 5*d.* The number of patients who attended the hospital during 1904 was 10,062, being 1756 more than in the previous year. The total number of operations was 9122, of which 2698 were extractions and 6424 preservative operations. In 338 operations anæsthetics were used. These figures bear ample testimony to the large amount of philanthropic work being done by the hospital among the suffering poor of the city. If, as is suggested, defective teeth are at the bottom of most of the dyspeptic ailments of the present day an institution such as this deserves every encouragement. We hear a good deal nowadays about preventive medicine but in this case we have a legitimate opening for preventive surgery.

Measles in Glasgow.

The medical officer of health reports that during last winter measles was very prevalent, especially in the eastern and southern districts of the city. Acting in coöperation with the school board on the principle that the closing of infants' sections should anticipate instead of follow the extension of the disease, action has been taken in a considerable number of instances during the winter and the results have been encouraging enough, although not spread over a sufficient time to show what the full value of the system may be as a method of stemming a rising tide of infection from measles.

Consumptive Sanatorium for Dumfriesshire.

A proposal was made some time ago to erect a sanatorium for the treatment of consumptives in Dumfriesshire. The movement has been going steadily forward and now it is announced that about £7000 have been collected in support of the scheme. It is proposed, to begin with, to make provision for 20 patients, leaving it to be afterwards discovered for how many more it is necessary to provide.

Fees for Attending Accidents.

Glasgow medical men are rebelling just now against what they consider the unfair treatment meted out to them in the case of street accidents. Where a policeman takes an injured person to a surgery an "ex gratia" payment is certainly made, but no recompense is made to the medical man in the many cases where the injured person is taken by a civilian and a policeman is afterwards called in. In all these cases, which are, of course, reported by the policeman to headquarters, no payment whatever is made and the medical man, in addition to the expenditure of time and labour, is put to the expense of the necessary surgical dressings. The Eastern Medical Society has taken the matter in hand and is pressing the claims of the medical men upon the attention of the "watching and lighting committee" which deals with such matters.

Lanarkshire Inebriates' Home.

Lanarkshire is in the unfortunate (or fortunate) position of having an inebriates' home and having no inebriates to put in it. The home at Hairmyres has only been in existence a few months and although it has no patients it seems, according to the convener of the committee, to have done good in a negative way already, as a number of those persons who had been often convicted have not been up during the last few months. One member of the committee suggested that in the meantime the building should be used as a consumptive home, but the general impression seems to be that unfortunately there will be no difficulty in getting inebriates to treat in the home.

Widal's Reaction.

The Clydebank and Renfrew joint hospital board has had before it a complaint by a local medical practitioner to the effect that a patient certified by him as suffering from enteric fever had been admitted to the hospital and discharged a few days later without any directions as to isolation and that after dismissal an examination of the blood gave a positive Widal reaction. The medical officer in charge of the hospital stated that he recognised the Widal reaction as a relative and not as an absolute test, and that he relied on the clinical diagnosis. If a patient could be cured with a dose of castor oil he would not detain him in hospital.

The Health of Aberdeen.

Dr. Matthew Hay, medical officer of health, reports that the death-rate from all causes during the month of April (17·72 per 1000 per annum) was considerably below the rate (19·26) for the preceding month and even still more below the rate (20·66) for the corresponding month of last year. Dr. Hay also reports that scarlet fever continued to decline, 12 cases with no deaths having been reported during the month, as against 16 cases with one death in the preceding month. Diphtheria greatly declined during the past two months, the number of cases notified in each month falling from 18 in February to eight in March and to two during the past month. There have been no deaths from this disease since January. Typhoid fever produced two cases during the month with one death. This is the first death from typhoid fever since last November and only the second death since April of last year. The epidemic of typhus fever, which gave cause for so much anxiety at the beginning of the year, appears now to be practically at an end. Except for one doubtful case removed for observation to hospital towards the end of the past month no case has been reported since April 11th. Six cases were notified in the early part of April but three of them were of cases which had been taken ill late in February or early in March but had not been sooner reported owing to the slight and somewhat doubtful character of the illness, the diagnosis having been rendered certain only by the occurrence of a subsequent undoubted case in each of the two families to which the cases belonged. The remaining three cases began in the last days of March, though not formally notified till the beginning of April, so that it may be said that the epidemic appears to have closed with the end of March. Four of the six cases notified were practically within one family and one case was that of a nurse at the City Hospital who had been nursing suspected cases. All of the cases have made a good recovery except one—a case of an old man whose daughter and grandchildren were suffering from typhus fever and who was believed to have had an attack of the same disease in early life. Erysipelas declined somewhat during the month, 17 cases having been notified as against 25 in the preceding month. There was one case of puerperal fever which terminated fatally. In the preceding month there was also one case, but up to that month there had been no case for four months. Measles declined greatly during the month, only 17 cases having been intimated or discovered, as against 55 in the preceding month. Three deaths were registered during the month, as against one in the preceding month. Whooping cough showed also a considerable decline during the month, 15 cases having been reported, as against 24 cases in the preceding month. One death was registered, as against four deaths in the preceding month. There were six deaths from influenza, as compared with 11 deaths in the preceding month.

May 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Ireland.

AT a stated meeting of the President and Fellows of the Royal College of Physicians of Ireland held on May 5th Dr. A. Traill, Provost of Trinity College, Dublin, was unanimously elected an honorary Fellow of the College.

Public Health of Ireland.

From the returns of the Registrar-General, which were published on May 17th, it appears that the number of deaths in Dublin for the month is only slightly better than that of three other districts which are dealt with in the report. Galway is very high, with an average of 34 per 1000, and Sligo is not far behind with 31, while in 15 of the areas the rate is about 20.

Irish Medical Association.

Much dissatisfaction has been caused among members of the association and others by the publication styled the "Irish Medical Directory for 1905" in which the qualifications of members appear in full and in black print while those who elected not to join the association are partially ignored. To judge by the resolutions which have been passed in Belfast and elsewhere that publication will not have a long life. It seems impossible to account for the recent action of the Irish Medical Association except one believes in the old Latin aphorism—that those whom the gods wish to destroy are first sent mad. Dr. L. Kidd of Enniskillen, Dr. R. Bodkin Mahon of Ballinrobe, and Dr. G. E. J. Greene of Ferns are all candidates for the direct representation of the medical men of Ireland on the General Medical Council in opposition to Sir William Thomson, who has been their representative for many years.—At a meeting of the North Down branch of the Irish Medical Association, held in the Medical Institute, Belfast, on May 18th, Sir W. Whitla was re-elected President for the ensuing year, and Mr. J. Wybrants Olpherts (Downpatrick) honorary secretary and treasurer.

Retirement of Dr. P. O'Keeffe of the Irish Prison Medical Service.

Dr. P. O'Keeffe has recently announced his retirement from the Irish Prison Medical Service after a career of 40 years. His resignation was signalised by an entertainment given to him by the chief officers of his department, including the chairman and other officials of the Prisons Board. Dr. O'Keeffe is well known in Dublin and Cork society and is highly esteemed. He has had many interesting criminals under his charge d[illegible] Dr. Kirwan, who was [illegible] of Ireland in his time, [illegible] on Ireland's Eye. Other and more modern criminals who have been under Dr. O'Keeffe's supervision would be more interesting to hear of now. It is hoped that at some time he will publish an account of his curious experiences.

The St. John Ambulance Association.

The annual inspection of the Belfast division of the St. John Ambulance Association was held in the large inclosure at the rear of the Central Fire Station, Belfast, on May 19th, and was in every way a success, Mr. J. C. Denham, assistant commissioner of the association, stating that the division represented by the fire brigade was one of the most efficient which he had examined this year. It was stated that last year the ambulance (worked by the fire brigade officials) was called into requisition 2393 times, and during the present year, that was, from the end of June, 1904, it had been in use on 2105 occasions.

May 23rd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Medical Superintendent Resigns after 29 Years' Service.

Dr. Charles O'Reilly, medical superintendent of the Toronto General Hospital, a position he has occupied since 1876, has resigned, his resignation to take effect on June 30th. When Dr. O'Reilly came from the hospital at Hamilton, Ontario, to take charge of what was ultimately to become the largest hospital of Canada, there were only 12 members on the acting and consulting staff, while to-day there is a staff of over 60. During the period of his superintendency 100,000 patients have been cared for in the wards, whilst in the maternity department some 4000 births have occurred. The hospital has gradually developed until to-day there is a constant floating population in the institution of some 500 people. Some years ago Dr. O'Reilly was instrumental in having established in the centre of the city an emergency hospital which annually attends to 2500 accidents and other emergency cases. Dr. O'Reilly will be entertained at a banquet by the profession of Toronto in the latter end of June. For a year or two he will travel abroad with his family.

Ontario Board of Health.

During the latter part of the month of April the regular quarterly meeting of the Ontario Board of Health was held in Toronto when the secretary, Dr. C. A. Hodgetts, presented the quarterly report of his department. He referred to the fearful mortality still prevailing throughout the province from tuberculosis, which had amounted to 500 lives for the first quarter of 1905, and urged the establishment of dispensaries for the treatment of cases of tuberculosis until such time as sanatoriums could be erected to take care of these cases. Dr. Hodgetts also took up the subject of the disinfection of Pullman and sleeping cars, which at the present time is not carried out in Ontario, and urged the board to recommend that legislation should be enacted in this direction. Notice of motion was given that at the next regular meeting of the board a discussion would take place upon the advisability of recommending the Government to establish a separate department of public health. The question of curtailing infant mortality was also considered and steps will be taken to lessen this through the coming summer months.

Professor W. Osler's Successor a Canadian Graduate.

Dr. Lewellys Franklin Barker, who has been appointed Professor of Medicine along with Dr. W. S. Thayer to succeed to the duties lately relinquished at Johns Hopkins University by Professor Osler, is a graduate of the University of Toronto of 1890. Dr. Barker was born near Philadelphia but early in his life his parents moved to Ontario, and Dr. Barker has received all his preliminary education in Canada. After graduation he entered the Toronto General Hospital for a year as house surgeon, going to Baltimore in 1892. In 1900 he was appointed to the chair of anatomy in the University of Chicago.

Ontario Hospitals Association.

The annual meeting of the Ontario Hospitals Association was held in Toronto on April 12th, the principal item of business being the formation of a special deputation to wait on the members of the provincial government asking for an increased grant to the hospitals of the province, to raise it from 50 cents per patient to 75 cents per patient. At the present time the Ontario Government gives annually to the hospitals of the province $110,000. The Premier has promised consideration of the subject. The statistics show that in the Ontario hospitals 39,223 patients were treated in 1904, as against 35,912 in 1903. The total revenue for these hospitals in that year amounted to $844,881, including the Government grant of $110,000. When divided this actually averaged 17 cents per day for each patient entitled to receive it, while the actual average cost of each patient was 89 cents per day. Mr. Edward Gurney of Toronto was elected President, Dr. Charles O'Reilly Vice-President, and Dr. John Ferguson, Toronto, secretary-treasurer.

British Columbia's Statistics for 1904.

The thirty-second annual report of the provincial registrar of British Columbia of the births, marriages, and deaths in that province in 1904 shows the registrations under the three headings to be as follows: births, 2139; marriages, 1252; and deaths, 1734. The figures for 1903 were: births, 2093; marriages, 1160; and deaths, 1572. Of the 2139 births in 1904 1121 were boys and 1018 were girls. Victoria and Vancouver, the two chief cities, contributed over one-half of the births, the figures for each being 471 and 593 respectively. The death-rate continues low. Under three years the deaths numbered 416; from 3 to 10, 69; from 11 to 21, 98; from 22 to 40, 484; from 41 to 60, 341; from 61 to 70, 169; from 71 to 80, 98; from 81 to 90, 45; and over 90, 3. Pneumonia claimed the greatest number of victims from any one disease, the number being 104. From tuberculosis the number was 79.

The Newfoundland and Labrador Medical Mission.

Dr. Wilfrid Grenfel, the English medical missionary who for the past 13 years has been devoting his life to the amelioration of the ills of the fisherfolk of Labrador and the north-west coast of Newfoundland, has been making his annual visit to New York, Toronto, and Montreal in the interests of his mission. Dr. Grenfel has been instrumental in establishing three hospitals amongst these people, and by the generosity of Lord Strathcona he has a hospital ship which during summer time he sails up and down the coast administering to the needs of the sick. In winter his dog team and sled carry him often 100 miles to a patient, and patients have been brought to him that distance on dog sleds. This summer Dr. Grenfel has secured the services of two young specialists of Boston to accompany him.

Toronto Clinical Society.

The last regular meeting of this society was held on the evening of May 3rd when the following officers were elected: President, Dr. Adam H. Wright; Vice-President, Dr. H. B. Anderson; recording secretary, Dr. George Elliott; corresponding secretary, Dr. W. J. McCollum; treasurer, Dr. Geoffrey Boyd; and executive committee, Mr. E. E. King, Dr. W. B. Thistle, Dr. R. J. Dwyer, Dr. D. J. Gibb Wishart, and Dr. H. J. Hamilton. The annual banquet was held on May 6th, when a most enjoyable evening was spent, most of the fellows and members being present.

News Items.

The Manitoba Medical College, Winnipeg, will erect a new medical building at a cost of $50,000.—The General Hospital, Montreal, is erecting a new administration building and two new wings at a cost of $200,000.—Dr. Francis Wayland Campbell, Montreal, Dean of the Medical Faculty of Bishop's College University, has died at the age of 58 years.—The Medical Faculties of Bishop's and McGill Universities, Montreal, are to amalgamate.

May 16th.

NEW YORK.

(FROM OUR OWN CORRESPONDENTS.)

Professor W. Osler's Retirement.

IN the end of April Professor Osler gave a farewell address at the annual meeting of the Maryland Medical Society at Baltimore on the subject of Unity, Peace, and Concord and this was followed by a banquet at which he was the principal guest and several excellent speeches were made. There have been several minor leavetakings at professional societies and a portrait is in process of being painted, but the chief compliment paid to him by his medical brethren occurred on May 2nd in a monster banquet at the Waldorf-Astoria Hotel, when some 600 physicians, surgeons, and gynæcologists assembled from all parts of the United States and Canada. The large hall was filled, the Stars and Stripes and Union Jack were mingled, and the two tiers of galleries were crowded with ladies. Dr. Tyson (Philadelphia) acted as chairman, or, as it is called here, toastmaster, and on Professor Osler's left was Dr. Keen, the Philadelphia surgeon. Other seats at the high table were occupied by Dr. Gibson, Dr. Dickinson, Dr. St. John Roosa, Dr. Malloch, Dr. Delafield (New York), Dr. Wilson (Philadelphia), Dr. Frank Billings (Chicago), Dr. Frederick Shattuck (Boston), Dr. Musser (Philadelphia), Dr. Shepherd (Montreal), Dr. Chadwick (Boston), Dr. S. Weir Mitchell (Philadelphia), Dr. F. M. Sandwith (London), Dr. John S. Billings (New York), Dr. Jacobi (New York), Dr. Welch (Baltimore), Dr. Polk, and Dr. Janeway (New York). Dr. Shepherd spoke of Professor Osler's able work in Canada from 1870 to 1884 and was followed by Dr. Wilson who spoke on Professor Osler in Philadelphia as teacher and clinician, and by Dr. Welch who spoke on Professor Osler in Baltimore as teacher and consultant. Then followed Dr. Jacobi who humorously praised him as an author and physician and then Dr. Weir Mitchell, after a most graceful speech, presented to the guest a beautifully bound copy of Cicero's "De Senectute," translated by James Logan and printed by Benjamin Franklin, both of Philadelphia. Professor Osler, in a most feeling speech, thanked all present for the overwhelming regard and friendship shown to him by his many professional friends. "I have had but two ambitions in the profession," he said, "first to become a good clinical physician and, second, to built up a great clinic at the Johns Hopkins University on Teutonic lines." During the evening some former pupils sang to the tune of the British National Anthem some impromptu verses, of which this is one:—

> "Look at his arteries,
> Judge of his age by these,
> Scarce thirty-five.
> May he ne'er pass his prime,
> In symptom or in sign,
> Younger in spite of time;
> Long live our chief.
>
> *Chorus*—God save the mighty chief,
> We part from him in grief,
> God save our chief."

The evening was a very eventful one and all agreed that no other member of the medical profession in America could have had such a farewell.

Yellow Fever in Panama.

Colonel Gorgas, chief sanitary officer of the American Isthmian Canal Commission, has recommended that no more employés be sent to the isthmus until suitable quarters can be provided for them. On May 8th Mr. R. R. West, auditor of the Panama Canal Commission, died from yellow fever in Panama.

Meningitis in New York.

There has been an increase in the number of deaths from cerebro-spinal meningitis in the week ending May 6th compared with the preceding week. The weekly death report of the department of health states that for the week ending May 6th there were 110 deaths from the disease in the city of New York, against 87 in the preceding week. In the two previous weeks there were 104 deaths and 117 deaths from this cause respectively. The Marine Hospital Service of the United States is for the first time keeping a separate record of deaths from cerebro-spinal meningitis. The reports of this service up to the present time, which are probably far from complete, give the number of deaths from the malady in the United States since July 1st, 1904, as 2856. The entire number of deaths from this cause in the State and city of New York is given as 2315. In New Jersey the deaths from the disease numbered 170 and in Massachusetts 74 cases proved fatal. As illustrating the deadliness of cerebro-spinal meningitis it is stated that of 231 cases of the disease reported to the Marine Hospital Service 167 proved fatal.

May 16th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Continued Excessively High Rate of Mortality from Plague throughout India.

THE plague epidemic continues with unabated virulence. For the week ending April 22nd 54,602 deaths were recorded, as compared with 51,786 for the preceding seven days. The death-roll for 1905 promises to exceed all former records. In 1901 the total deaths from plague were returned at 273,679, in 1902 the number rose to 577,427, in 1903 it reached 851,263, and in 1904 it was 1,022,299. From Jan. 1st of the present year up to April 15th the number of fatal cases is reported at 576,366 and it is very doubtful whether these figures tell the whole truth. Of the total of 64,214 seizures with 54,602 deaths during the week ending April 22nd the Bombay Presidency had 3497 cases and 2787 deaths; Madras, 65 cases and 65 deaths; Bengal, 4993 cases and 4351 deaths; the United Provinces, 18,249 cases and 16,637 deaths; the Punjab, 33,162 cases and 27,362 deaths; Burma, 183 cases and 175 deaths; the Central Provinces, 223 cases and 175 deaths; Mysore State, 50 cases and 40 deaths; Hyderabad State, 401 cases and 316 deaths; Central India, 117 cases and 24 deaths; Rajputana, 2924 cases and 2406 deaths; and Kashmir, 359 cases with 215 deaths. These detailed figures will show how the disease has extended over the country and the heavy mortality of the cases. The mortality is higher this week in the Punjab by 3420; in the United Provinces by 753; in Rajputana by 200; in Burma by 20; in Kashmir by 28; in Bombay city by 132; and in Calcutta by 130. The only noticeable decrease is in the districts of Bengal, where the epidemic seems to be abating. In this area, however, the outbreak occurred earlier in the season. During the present outbreak the anti-plague serum from the Pasteur Institute in Paris has been somewhat extensively used for the treatment of cases both in Bombay and Calcutta and although it is early to form a definite opinion numerous individual reports would seem to show its value.

The Encouragement of Inoculation against Plague

A somewhat novel proposal was made to the Government of Bombay that it should pay to the family of anyone who died from plague within one year after inoculation the sum of 100 rupees. This suggestion was not accepted by the Government of Bombay, which, moreover, in answer [illegible] usiasm for inoculation, [illegible] ss its support. It is very [illegible] shows its own faith in inoculation, and not only expresses it freely but offers some tangible inducement to the people, the benefits of this prophylactic are not likely to be taken advantage of by the masses. Another proposal has been put to the insurance companies—viz., that they should offer some form of assurance against death from plague and at the same time encourage inoculation by giving favourable terms to those who have been protected. The insurance companies might go even further and, following the principle of the sanatoriums for consumptives maintained in Germany by the insurance companies there, offer to give medical treatment to their inoculated clients attacked with plague. The risk of death from plague, even after inoculation, could be still further reduced by the use of anti-plague serum.

May 4th.

Obituary.

PROFESSOR EZIO SCIAMANNA.

PSYCHOLOGICAL research in the experimental laboratory and the clinical ward loses an accomplished and indefatigable votary in Dr. Ezio Sciamanna who died suddenly in Rome on May 15th. He had taken an effective part in the proceedings of the International Congress of Psychology recently held there and at its close complained of recurrent lancinating pains over the region of the heart. An attack of bronchial catarrh from which he had partially recovered but which was still active enough to induce frequent fits of coughing seemed to aggravate, if not to provoke, the cardiac symptoms and it was on the occasion of one of these said fits that early on the morning of the 15th he experienced a sudden sensation as if of impending asphyxia. Professional aid was at once in attendance but without avail and after a few convulsive seizures, accompanied by apnœa very painful to witness, he passed away.

A Roman by birth, having been born in the suburbicarian diocese of Albano in 1850, Ezio Sciamanna was educated at the metropolitan University and proceeded in due course from the faculty of arts to that of medicine in which he graduated with distinction in 1876. Having chosen medico-psychology as his special walk he made a series of visits to the great schools of the Continent and the British Isles, spending most of his time at those of Paris and London, in the former of which he gave much attention to the courses of Charcot and Magnan. Thanks to these he returned to Italy with unusually sound and varied equipment in psychological medicine and in 1881 was appointed "Liberodocente" in neuro-pathology in the Roman University. Four years thereafter he was promoted to the chair of Clinical Psychiatry in the same school and in conjunction with his colleague, Dr. Giuseppe Sergi of the Institute of Experimental Psychology and Anthropology, he founded the *Rivista di Psichiatria e Neuropatologia* which soon achieved an authoritative place among its sister periodicals and which still enriches its special subject matter with the same staff of contributors under its new name and form of the *Annali della Clinica Psichiatrica*. Sciamanna's contributions to both journals are over 100—hardly one of them without distinct merit for independent observation and research and for a truly "Latin" lucidity and charm of style. He was the first of his professional compatriots to prosecute experiments on the "electric excitability of the cerebrum humanum," while his communications on "cerebral tumours," on "constructional psychoses," on "psychic tic," and cognate lesions or maladies have found honourable mention in more than one treatise—Italian and English, French and Austrian, German, Dutch, and Danish. At the recent International Congress he read a paper on the thesis that the psychical functions are not the special outcome of one part of the encephalon only but that they energise in necessary relation with the "attività complessiva dell' intero encefalo" (the combined action of the encephalon as a whole). He strengthened his position with observations on apes and vindicated them in the discussion which followed with a dialectic skill and a cogency which made his contribution one of the most memorable of the congress. Apart from his work in medico-psychology Sciamanna was a strenuous antagonist of obscurantism in all its forms, and though an ardent and uncompromising combatant never failed in the courtesy due to sincere, if mistaken, controversialists. These truly chivalresque qualities endeared him to colleagues and pupils alike, while his "sense of citizenship," all too rare in Italian public life, roused him on occasion to intervene in the municipal and even the political arena, when interests cherished by all enlightened sons of Italy and of Rome appealed for vindication or support. He was a "Consigliere della Congregazione di Carità"—a post in which he showed that true benevolence which is all the more appreciated that it is circumspect and discriminating. He was buried on May 17th in the family vault at the Campo Verano in the presence of numerous colleagues, pupils, past and present, and prominent citizens.

GEOFFREY RICHARD SLADE, M.A., M.D. CANTAB., M.R.C.P. LOND.

AFTER a short illness Dr. G. R. Slade died at the London Hospital on May 16th in his thirty-third year, having been on duty at the Pathological Institute of the hospital within a week of his death. He was educated at Charterhouse and Trinity College, Cambridge, where he had a distinguished career as a classical scholar. After obtaining first-class honours in 1893 he selected medicine for his future profession and entered the London Hospital as a third-year student in 1896. He qualified in 1900 and held the usual resident appointments. Three years ago he became associated with the Pathological Institute, of which he was director at the time of his death. In this capacity he did much good work, a specimen of the results of which appeared a few weeks ago in THE LANCET. Professionally he was a most conscientious worker with a true love of science and a great knowledge of medicine and pathology which he was able to impart in a lucid and convincing style.

As a colleague the truthfulness and straightforwardness of his character commanded the deepest respect and his faultless unselfishness inspired everyone with the sincerest admiration and devotion. As an individual his manifold virtues endeared him to all. He was the recipient of many confidences and his large stores of wisdom and sympathy were in constant request. So passes from among us one of the most promising of the rising generation of physicians. Proficient not only in medicine but also in letters and philosophic thought, he was the embodiment of a type of which the profession, as well as his fellow workers and friends, might well be proud. He died from septicæmia contracted in the performance of his work, and by his death another name is added to the long roll of martyrs in the cause of medical science. To those who mourn him we offer our sincere sympathy.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Eugène Hubert, professor of midwifery in the University of Louvain, at the age of 66 years.—Dr. Yêrofêieff, formerly professor of ophthalmology in the University of Tomsk.—Dr. Conrad Eckhard, professor of physiology in the University of Giessen, at the age of 83 years. He published many valuable works on anatomical and physiological subjects.—Dr. Samuel von Bash, extraordinary professor of experimental pathology in Vienna. His published works cover a wide range and include very interesting accounts of the reign of the ill-fated Emperor Maximilian whom he accompanied to Mexico. His name is also well known in connexion with a sphygmomanometer which he devised.

WATER-SUPPLY OF WOOLACOMBE.—At the meeting of the Ilfracombe (Devon) district council held on May 17th it was stated that the inhabitants of the little watering-place of Woolacombe had decided on taking the water-supply from the Ilfracombe district council.

MIDLAND MEDICAL UNION: CHESTERFIELD BRANCH.—The annual dinner of this association was held on May 11th at the Portland Hotel. Dr. G. Godfrey Macdonald, the President of the Union, occupied the chair, and Dr. J. G. Shea (in the unavoidable absence of Mr. R. G. Allen, the Vice-President) was in the vice chair. Amongst those present were Dr. George Booth, Dr. W. Dyson, Mr. R. J. Pye-Smith, Mr. J. F. Cheesewright, Dr. S. Worthington, Dr. J. W. Martin, Dr. H. J. Rankin, Dr. Arthur J. Hall, and many others, together with Mr. G. S. O'Rorke, LL.D. (general secretary). The toast of "The Midland Medical Union" was proposed by Mr. Cheesewright and responded to by the President. The toast of "The Guests" was proposed by Dr. Booth, the ex-President, and responded to by Dr. Martin and Mr. W. H. Rowthorne. An informal discussion took place on matters relating to the objects of the union and interchange of experience in attaining fair and reasonable remuneration for medical contract services by unity of action in particular districts.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 23RD.

THE eighty-first session of the General Council of Medical Education and Registration was commenced to-day at the offices, 299, Oxford-street, London, W., Dr. DONALD MACALISTER, the President, being in the chair.

New Members.

Sir Thomas Myles, appointed by the Royal College of Surgeons in Ireland as a member of the Council in room of Sir Charles Ball, was introduced by Sir William Thomson and took his seat. Dr. Arthur Atock, appointed by the Apothecaries' Hall of Ireland as a member of the Council to succeed the late Mr. C. R. C. Tichborne, was introduced by Dr. Little and took his seat.

The President's Address.

[The PRESIDENT commenced his address by referring to the losses sustained by the Council through the deaths and resignations of members and officials. He continued:—]

I would now allude briefly to certain matters which have occupied my attention during the recess. In accordance with your resolution of Nov. 29th I addressed a communication to the Lord President of the Privy Council on the subject of medical and dental companies and of the abuses to which they give rise. The Lord President, in reply, asked for detailed evidence in support of our representations. This evidence the Registrar, with the help of members of the Companies Bill Committee, was enabled to collect and to forward. It is now under the Lord President's consideration. It will be remembered that, according to the judgment of Chief Baron Palles, a dental company whose proposed title is such as to mislead the public into supposing that its business is carried on by qualified persons may lawfully be refused registration under the Joint Stock Companies Acts. The question arose whether a company already registered, whose title was open to the same objection, might lawfully remain upon the register. A judgment in the negative has now been given in the High Court of Justice in Ireland by the Master of the Rolls in the case of the Attorney-General *versus* Appleton and others. This important decision was made the subject of questions in Parliament by Sir John Tuke who has been most active in pressing the matter on the attention of the Government; and I communicated a full report of the case, courteously furnished by the British Dental Association, to the Lord President. The purpose of these questions and communications was to ascertain what steps could be taken to procure a similar declaration of the law in Great Britain. The replies will be laid before you. The last of them, received on Saturday, is of primary importance to the dental profession, but the underlying principle admits of a much wider application. The documents indicate that definite advance is being made in the direction desired by the Council in its resolution of May 31st, 1904, and you will doubtless refer them to the Companies Bill Committee for its information. As the result of a confidential communication from the Army Council this Council on Nov. 22nd, 1904, appointed a committee to inquire into the operation of the Anatomy Acts and their effect on the teaching of anatomy and practical surgery in Great Britain. A further communication from the War Office was received in March, from which it is apparent that the inquiry you directed is of pressing importance. To facilitate the work of the committee I have opened communications with a number of the authorities concerned, and the information thereby obtained, much of which is of a confidential character, will require careful consideration. The Office Site Committee, with the valuable aid of your solicitor, has been occupied in arranging for the future tenancy of the Council's house in Hanover-square, the existing lease of which expires at Midsummer next. The negotiations have been protracted and sometimes difficult but I may be allowed to anticipate the report of the committee so far as to say that we have now found a satisfactory tenant at a rent considerably larger than that hitherto obtained and on conditions which the Council has already approved in advance.

The Council will also learn with satisfaction that the accounts for the year 1904 are more favourable than those for any year since 1895. At the end of 1903 our deficit was some £2165; at the end of 1904 it was only £218, or about one-tenth as great. The Finance Committee will report on the items which have contributed to this substantial improvement, but it is noteworthy that the result is attributable not to any increase of ordinary income but to greater economy of expenditure. Whether this degree of economy can be maintained in future years without impairing the Council's efficiency it is difficult to forecast. But though I may be, as I have been, charged with incurable optimism regarding the Council's finances I still think that in ordinary years equilibrium between income and expenditure is possible of attainment, even without the aid of fresh legislation, and I am strengthened in this belief by the opinion of the Finance Committee. If the vigilance of your officers is supported by the resolve of the Council to discountenance all expenditure of time and money that does not directly conduce to efficiency it is not extravagant to hope that the accounts of the coming years may be even more satisfactory than the last. The closing year of office of my distinguished predecessor in the chair has shown us what can be done in this direction and it will be my ambition to assist to the best of my power in maintaining the ground we have gained under his leadership. But while we strive after economy on the one hand we must not neglect any legitimate means for the improvement of our income on the other. Where the equilibrium is precarious even a small addition to the right side of the balance is important. Dr. Mackay's suggestion—that the fees for the restoration of lapsed names to the registers and for the registration of higher titles should be slightly raised—has proved to be fruitful, for it has added over £400 to the receipts of the year. The higher fee, so far as it represents a fine for negligence, will incidentally tend to keep the registers more correct. The fee for recording additional qualifications, being, as it were, a small tax on new dignities, is paid with comparative complacency by the newly dignified. Dr. Mackay's proposal is thus abundantly justified and the Chancellor of the Exchequer in search of fresh sources of revenue might well take counsel with him.

The suggestion has been made from an important quarter that one of the services gratuitously performed by the Council might be made self supporting in a similar way. I refer to the maintenance of our Students' Registers. The General Registrar, with the help of the branch registrars, has ascertained that the ordinary expenditure on this branch of our work—for printing, postage, salaries, and time occupied in committees and councils over its details—may be estimated at about £400 a year. Against this outlay the only receipts are some £20 a year from fees for late or exceptional registration. If a fee, say, of 5s. were charged for the certificate of registration in ordinary as well as exceptional cases the actual cost would just be covered and the Council's funds would be relieved to a corresponding extent. It is represented that for such a step no new legislation would be required, that the Students' Registers might remain on their present "voluntary" basis, that the trifling fee would be readily paid and easily [illegible] the Council and of [illegible] registration would [illegible] entations are just, and I offer them for your mature consideration, the Council might be well advised to make the experiment. The improvements in the office sanctioned at the last meeting have been carried out under the supervision of the General Registrar and, thanks to his care and [illegible] well within the estimate. T[illegible] better keeping of the register[illegible] to registration has now been provided and the new system, already tried and approved in the dental department, is being rapidly applied to the others. The expense in this case will certainly contribute to efficiency. The like statement may also be made regarding the outlay on cleaning and redecorating the Council chamber. This work had been postponed until it was certain that our occupancy of the premises would continue. When the doubt was finally removed the Registrar was instructed to put the chamber and galleries into tenantable condition. The work of the [illegible] when it is carried [illegible] reports of the [illegible] es of Oxford and London would be brought before the Council by the Examination Committee. In his opinion they were highly satisfactory. After referring to the Pharmacopœia Committee the President announced that the penal cases would be heard on Wednesday and Thursday and concluded his address by assuring the chairmen of committees and other members of the Council of his willingness to assist them in every possible manner.]

On the motion of Dr. WINDLE the President was thanked for his address, which was ordered to be printed in the minutes.

The Business Committee.

Dr. NORMAN MOORE moved that the following members should compose the Business Committee: The President, Dr. Windle, Dr. Bruce, Sir Christopher Nixon, and Mr. Young.

Sir JOHN MOORE seconded the motion, which was agreed to.

Yearly Examination Tables.

On the motion of Dr. WINDLE, *seconded by Dr.* NORMAN MOORE, the following yearly tables for 1904 were received and entered on the minutes:—

[illegible] for commissions in the [illegible]

Vote of Thanks.

Sir PATRICK HERON WATSON moved:—

> That the th[illegible] of the Medi[illegible] General of the [illegible] for India resp[illegible] to the Counci[illegible] tinue to be furnished to the [illegible]

Dr. MCVAIL seconded the motion which was agreed to.

Restoration of Name.

The Council having sat *in camerâ*,

The PRESIDENT intimated that the Council had resolved to direct the Registrar to restore to the Medical Register the name of Samuel B. Shekleton.

Amendment of the Companies Acts.

The PRESIDENT said he had now to lay before the Council a statement of the steps taken since November, 1904, in regard to the suggested amendment of the Companies Acts by himself and also by Sir John Batty Tuke, to whom they owed a great deal for having pressed these matters on the attention of the Government. The latest expression of opinion by the Privy Council was contained in the following letter:—

> Privy Council Office, May 19th, 1905.
>
> SIR,—Referring to your letter of 17th inst. on the subject of the registration of medical and dental companies and inquiring whether, in view of the decision of the Master of the Rolls in Ireland in the case of the Attorney General for Ireland v. Appleton and others, the [illegible] General for England would take similar proceedings in the [illegible] matter, [illegible]
>
> I am, &c.,
>
> (Signed) A. W. FITZ ROY.
>
> The Registrar, &c.

The process should be that through the Attorney-General who must consent to act an injunction should be asked for to prevent a company already registered with a title which had been misleading from remaining on the register of joint-stock companies If one good case were brought up and the decision were the same as that given in Ireland that would mean that a number of companies with misleading titles in connexion with medical and dental practice might be removed from th[illegible] companies. The sugg[illegible] Association should t[illegible] position, no doubt, to [illegible] case and present it in a proper form and in proper course. He moved that the documents in connexion with the matter be placed before the Companies Bill Committee to be considered.

Mr. TOMES, in seconding the motion, said that the Council was deeply indebted to the President for bringing about this result.

The motion was agreed to.

It was agreed to enter the report in the minutes of the day.

Request for Change of Designation.

The Council considered the report of the Executive Committee in regard to the petition from 767 Licentiates of the Apothecaries' Society of London requesting an alteration in the Medical Register of the designation therein given to the qualification granted by the Society.

The report was ordered to be entered on the minutes.

The PRESIDENT said the prayer of the petition was as follows:—

> Your petitioners therefore humbly pray that the General Council will forthwith order that, in respect of all persons who have passed or shall pass the qualifying examination of the Society conducted in manner prescribed by the Medical Act, 1886, and have received or shall receive the diploma of the Society, the qualification entered or to be entered in the Medical Register shall be changed from "Licentiate of the Society of Apothecaries" to "Licentiate in Medicine, Surgery, and Midwifery of the Society of Apothecaries," or such abbreviation thereof or other title as shall indicate that the persons holding the said qualification are legally qualified to practise in medicine, surgery, and midwifery.

He would direct the attention of the Council to the Medical Act of 1858 which governed this matter. It described the qualifications that were to be registered. After consideration of all those points the committee had no option but to come to the conclusion that without a change on the schedule of the Acts, which would require fresh legislation, the Registrar would not be justified in changing the designation of the Licentiates of the Society of Apothecaries.

Sir HUGH BEEVOR supported the recommendation of the Executive Committee.

Dr. WINDLE moved the approval of the report which was seconded by Dr. NORMAN MOORE.

Sir THOMAS MYLES said that apparently the Council had no power to alter the title, but he would like to know whether they might not suggest to those gentlemen how they were to get the alteration which they desired.

Dr. ATOCK agreed with the suggestion of Sir Thomas Myles.

Mr. BROWN hoped that the Council would do more than simply acknowledge the petition.

Sir CHRISTOPHER NIXON submitted that the application for the change which the Licentiates desired should come from the body itself. They had no right to interfere with the status or title of a body simply on the application of the Licentiates. If the body made an application to the Council the Council would point out that they would have to obtain an Act of Parliament for the privilege they wanted and that the Council would be prepared to assist in obtaining that. He thought that the Society of Apothecaries had an extremely strong case.

Dr. NORMAN MOORE said that he took an entirely different view. There had been prevalent in their profession an unfortunate desire, which he thought ought to be discouraged, to claim titles which had not been earned. They constantly heard that people who passed a certain examination were quite as good as those who had studied at the University and who had the degree of doctor. This was a degrading tendency, against which the Council should set its face. The Society of Apothecaries of London had an honourable history and if he were a Licentiate he should be proud of the title and not anxious to assume another.

The PRESIDENT said that there was no intention on the part of the committee to send a curt reply to the petitioners. The petitioners asked a definite thing and it was wise on the part of the Council to confine itself to a definite answer. The petitioners did not ask the Council to help them to obtain fresh legislation or to promote a Bill in Parliament. The finding of the committee was a precise answer to a well formulated and clear question. The Council placed on the certificate of registration the statement that the qualification was a complete qualification for medicine, surgery, and midwifery, and on the first page of the Register there was a statement to the same effect. Mr. Muir Mackenzie advised the committee that that was the utmost extent to which their legal powers enabled them to go. It showed that the Council was anxious to make it clear to the public that those gentlemen were fully qualified.

The motion was agreed to and the report approved.

Investigations by Medical Unions.

The Council next considered the petition from the County of Durham Medical Union requesting that when cases have been investigated by their society or any similar one the General Medical Council should accept the conclusions arrived at and take action accordingly. In reference to this petition the Executive Committee recommended that a reply should be sent pointing out that in all proceedings before the Council the rules of evidence in judicial proceedings in courts of law must as far as possible be followed and that accordingly the suggestion of the petitioners was one that the Council was unable to adopt.

The report was received and entered on the minutes.

The PRESIDENT pointed out that the legal advisers of the Council had again and again insisted that the rules for evidence in judicial proceedings in courts of law must so far as was practicable be followed.

Dr. WINDLE moved approval of the recommendation of the Executive Committee.

This was seconded by Mr. JACKSON and agreed to.

Invalid Medical Certificates.

The Council took up a communication from the British Medical Association which was referred to the General Medical Council by the Executive Committee for its information.

> On May 24th, 1904, a communication was read to the Executive Committee from the Medico-Political Committee of the British Medical Association forwarding a communication from the education committee of the borough of Bootle in regard to the giving of a medical certificate by a person described as a local chemist and druggist in the case of a girl unable to attend school, whereupon the following resolution was passed: That the attention of the Medico-Political Committee of the British Medical Association be called to Section 37 of the Medical Act, 1858; that they be informed that on the face of it the certificate forwarded to the Council appears to be invalid under that section and that the Council has no jurisdiction over chemists who give invalid certificates.
>
> On Nov. 21st, 1904, a further communication on the subject was considered by the committee and the whole correspondence was remitted to the General Council, by whom it was considered on Nov. 24th and 25th, 1904, on the latter of which dates Mr. Muir Mackenzie gave an opinion to the effect that:—
>
> Although Section 37 of the Medical Act, 1858, imposes a statutory duty on public bodies not to accept in specified cases certificates given by unregistered persons, there is no statutory penalty against either a public body for accepting or an individual for giving invalid certificates, but if the public body acted so systematically in this way as to create a public mischief the Attorney-General might intervene to prevent the provisions of the Act from being contravened. If a public body is not required by statute to receive certificates signed only by medical practitioners, it can accept certificates if it chooses from chemists or unregistered persons.

A further communication had been received from the British Medical Association. The medical secretary, referring in this letter to statements made by members of the General Medical Council, said statements appeared to have been made that the "certificate" was written on a chemist's memorandum form and that it purported to be signed by a chemist and druggist.

The letter proceeded:—

> I enclose the certificate and am instructed to point out that it is given on a printed form issued by the local education authority and headed "Form of Medical Certificate," and the document contains no indication that the person who signed it was not a registered medical practitioner.
>
> It will also be observed that this is not a case, as was suggested in the debate in the General Medical Council, i[illegible] authority knowingly accepted certificates of [illegible] from others than registered medical practitioners, but, on [illegible] the local education authority, on finding out that the signatory was not a medical practitioner, did not accept the certificate but brought it to the notice of the British Medical Association.
>
> It appears to the Medico-Political Committee that the exact form of this certificate is a matter of public importance as affecting the question whether the law at present makes adequate provision against imposition upon the public by the signing, by persons other than registered medical practitioners, of documents which purport to be medical certificates. I am, therefore, instructed to request that you will be so kind as to bring this letter before the Council in order that the form of the certificate in question may be made known to the Council and may be reported in its public proceedings, thus correcting misapprehensions to which the report of the debate in November last is found to have given rise.

BOOTLE EDUCATION COMMITTEE.

FORM OF MEDICAL CERTIFICATE
(for Educational purposes).

Bootle: *13th Feb., 1904.*

I hereby certify that *Elizabeth Hickey*, of *81, Seaforth St.*, is suffering from *Impetigo on back of head*, and is not fit to attend school, but will probably be able to return in *Two* { weeks. / months.

P. Williams,
123, Derby Road.

Sir VICTOR HORSLEY moved that the communication be received and entered on the minutes.

The PRESIDENT, in seconding the motion, said he was afraid he was responsible for some of the misapprehension that had existed in the debate. He was glad the certificate in question had been produced.

The motion was agreed to.

Mr. BROWN suggested that some action should be taken.

The PRESIDENT said that if Mr. Brown wrote out a motion indicating the action he wished to take they would then discuss it.

Dental Business.

The Executive Committee presented the following report on the dental business transacted since the last meeting of the Council:—

himself and various Government departments and the chairman of a departmental committee of the Board of Trade on the operation of

if possible, in coöpera-

tion with the Medical Counc

society the right to continue

answer to this communication

direction of the President.

On the motion of Dr. WINDLE, seconded by Dr. NORMAN MOORE, the report was received and entered on the minutes.

Visitation and Inspection of Qualifying Examinations.

The Executive Committee presented a series of revised standing orders for adoption by the Council relating to the visitation and inspection of qualifying examinations.

The PRESIDENT said that at the last meeting some ambiguity was discovered in the standing orders, and the Executive Committee had considered the matter, and the orders now proposed were the result of its consideration. The only question was whether they would express more clearly what the Council had acted upon for years. There was no change.

On the motion of Dr. MCVAIL, seconded by Sir VICTOR HORSLEY, the Council went into committee to consider the orders.

Dr. WINDLE moved the adoption of the first rule—viz.:

in

on

Dr. MCVAIL said that he had no objection to the rule if it were interpreted in the sense that visitation and inspection were to be distinct and different. If visitation and inspection meant the same thing he asked that the matter should be further looked into.

The PRESIDENT said that Dr. McVail was anticipating the discussion on the other rules. They had more than one legal opinion that visitation was a right conferred upon them by the Act of 1858, which could be carried out at any time they pleased, and that inspection was a right conferred upon them by the Act of 1886 which could also be carried out at any time. Therefore inspection and visitation could be carried out together if they thought fit. This rule did not force them to combine the two if they chose not to do so. He would point out that the tenth rule said that it would be the duty of the visitors and inspector to report "jointly or severally." The word "reports" was also used.

The motion was agreed to.

The second standing order was also approved after some discussion. Its terms were:—

The visitations shall be conducted by one or

Act, [illegible].

At this stage the Council resumed and then adjourned till the following day, when the time was taken up by the consideration of penal cases.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the first examination of the Board at the April quarterly meeting of the examiners in the subjects indicated:—

pool; Stanislaus Joseph Lauder, London Hospital; James Arthur Richard Lee, Sheffield University; Frederick Martin Lipscomb,

Charing Cross Hospital; and John Pryce Williams, Manchester University.

Practical Pharmacy.—John Henry Dyke Acland, St. Thomas's Hospital; Charles Amarasuriya, Ceylon Medical College and King's College Hospital; Berkeley Noel Ash, St. Bartholomew's Hospital, Harold Percivall Aubrey, Thomas Frederick Brown, Sidney Howard Browning and Vincent Ackroyd Palliser Costobadie, Guy's Hospital; Charles William Treskilder Baldwin, Charing Cross Hospital; Edward John Blewitt, Leonard Howard Bowkett, and Malcolm Ogden Cruickshank, London Hospital; Percy John Chissell, Middlesex Hospital; Cecil Ernest Clay, Yorkshire College, Leeds, and Edinburgh University; George Leslie Curnock, John William Doherty, and Frederic Nicklin Doubleday, private study; Sidney Herbert Daukes, Cambridge University and London Hospital; Adolf Henry Coombs Dawes, University College, Bristol, University College, and Westminster Hospitals; George Bennicke Edwards, London Hospital; Henry Granger, St. Thomas's Hospital; George Frederick Greening, Guy's Hospital; Cyril Verity Griffiths, King's College Hospital; Bernard George Gutteridge, private study; Reginald Beaumont Heygate, Middlesex Hospital; Richard Rossiter Huxtable, Charing Cross Hospital; Robert Rutson James, St. George's Hospital; David Morgan Jones, Glasgow University and London Hospital; Arthur Rieussett Littlejohn and Urban Marks, St. Mary's Hospital; Albert Lawrence Loughborough, St. Thomas's Hospital; Thomas Fletcher Lumb, Cambridge University and Middlesex Hospital; Owen Reginald McEwen and Echlin Storey Molyneux, London Hospital; [illegible] George Gordon Rigby, and Robert [illegible] hester University; Albert Clifford [illegible]; Cecil Walpolo Richard Preston, Guy's Hospital; Harold Edgar Priestley, St. George's Hospital; James Edmund Smith, Alan Richmond Snowdon, Charles Fitz-Gerald Willes, and Kenneth Wolferstan, St. Bartholomew's Hospital; William Hugh Raymond Streatfeild, Cambridge University and St. George's Hospital; George Thom, King's College Hospital; Harold Thomsett Treves and James Montague Wyatt, St. Thomas's Hospital; Richard Grenville Vaughan, University College, Bristol; and Harold Douglas Wyatt, Guy's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—A. Bernfeld (Section I.), Royal Free Hospital; J. A. Davies (Section II.), Manchester; J. W. Rollings, Charing Cross Hospital; J. L. Schilling (Sections I. and II.), Leeds; I. C. Thorburn (Section II.), Liverpool; J. A. R. Wells (Sections I. and II.), St. Thomas's Hospital; G. Wilmersdoerffer (Sections I. and II.), Royal Free Hospital; and R. W. L. Wood (Sections I. and II.), Leeds.

Medicine.—R. Heathcote (Sections I. and II.), Manchester; W. V. Pegler (Section I.), Leeds; C. A. Sampson (Sections I. and II.), Charing Cross Hospital; and J. L. Schilling (Sections I. and II.), Leeds.

Forensic Medicine.—J. B. Bradley, Birmingham; W. G. H. Cable, London Hospital; W. L. Crabtree, Leeds and Charing Cross Hospital; A. G. C. Findlay, University College Hospital; R. J. O. Harley, Dublin and McGill; R. Heathcote, Manchester; W. A. King, Charing Cross and St. George's Hospitals; W. S. Mitchell, St. Mary's Hospital; W. G. O'Malley, London Hospital; J. L. Schilling, Leeds; and A. L. Walters, St. Thomas's Hospital.

Midwifery.—W. V. Pegler and J. L. Schilling, Leeds; R. Spears, University College Hospital; and E. Sutcliffe, Leeds.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: J. B. Bradley, J. A. Davies, R. J. O. Harley, J. W. Rollings, J. L. Schilling, I. C. Thorburn, J. A. R. Wells, and R. W. L. Wood.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

C. A. K. Ball, B.Ch., &c., Univ. Dublin; J. J. Bell, L.R.C.S.I., &c., Edin.; J. S. Dunne, L.R.C.S.I., &c.; P. H. Falkner, L.R.C.S.I., &c., Captain R.A.M.C.; W. H. Hornibrook, L.R.C.S.I., &c.; J. P. Marnell, L.R.C.S.I.; T. J. Nicholl, L.R.C.S.I., &c.; and J. P. Ziervogel, L.R.C.S.I., &c.

The following have passed the primary part of the Fellowship examination:—

J. M. Alcorn, student, R.C.P. & S.I.; C. M. Benson, B.Ch., &c., Univ. Dublin; J. B. Butler, student, Royal Univ. Ireland; H. M. Johnston, B.Ch., Royal Univ. Ireland; J. M'Namara, student, R.C.P. & S.I.; and A. A. Murphy, student, R.C.P. & S.I.

TRINITY COLLEGE, DUBLIN.—At the previous medical examination the following passed in the subjects indicated:—

Anatomy and Institutes of Medicine.—Bethel G. H. Solomons and Arthur E. Knapp.

Physics and Chemistry.—Thomas P. S. Eves, James P. S. Dunn, and Francis W. H. Bigley.

Botany and Zoology.—Richard H. Mathews, Thomas A. Watson, Henry H. James, and James D. Murphy.

At the final examination in surgery held in Trinity Term the following candidates were successful:—

William J. Powell, George MacG. Millar, Charles R. Morris, John Murdoch, Joseph W. Houston, Henry H. A. Emerson, William Nunan, John A. Pringle, Cecil A. Boyd, William G. Harnett, Cecil Scaife, Montgomery D. Ferguson, Charles C. Williams, and William F. Samuels.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. Emilio Cavazzani of Padua has been recognised as *privat-docent* of Pharmacology.—*Florence:* Dr. Nazareno Tiberli has been recognised as *privat-docent* of Bacteriology.—*Budapest:* Dr. Johann Wenhardt has been recognised as *privat-docent* of Internal Medicine.—*Prague (German University):* Dr. Friedrich Ganghofner and Dr. Alois Epstein, Extraordinary Professors of Children's Diseases, have been promoted to Ordinary Professorships.—*Vienna:* Dr. Robert Brewer has been recognised as *privat-docent* of Internal Medicine and Dr. Otto Loewi as *privat-docent* of Pharmacology and Toxicology.

H.R.H. the Duchess of Albany has promised to attend a garden fête to be held at the Manor House, Stoke D'Abernon, Surrey, by kind permission of Mr. and Mrs. F. A. Phillips, on Saturday, June 17th, in aid of the funds of the Royal Waterloo Hospital for Children and Women.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a meeting of the President and Fellows of the College held on May 5th, Dr. A. Traill, Provost of Trinity College, Dublin, was unanimously elected an Honorary Fellow of the College.—The Licence in Medicine of the College has been conferred on Mr. J. E. St. George Queely and the Midwifery Licence on Dr. A. C. Dondy.

VOYAGES D'ÉTUDES MÉDICALES.—The recent visit to Paris of so many British medical men has caused renewed interest in this organisation. It was started by Dr. Carron de la Carrière and is a scheme for bringing the merits of the French health resorts into greater prominence than they now enjoy. For the purposes of the scheme France is divided into five districts. Each year a separate district is taken and the health resorts in that district are visited and examined in detail. This year's voyage is to be to the Pyrenees and the stations included will be, among others of the spas, Luchon, Barèges, St. Sauveur, Eaux Bonnes, and Eaux Chaudes, and of the health resorts Pau, Biarritz, and Arcachon. A feature of this journey is Lourdes to which great interest attaches from a psychological standpoint. The number of British adherents to the Voyages d'Etudes Médicales has hitherto been small and it would be highly fitting and very gratifying if the excellent relations recently established could be cemented by a considerable accession to the number this year. The time of the year selected is the first week in September; the price is very moderate, amounting to about £12 for a fortnight's travelling and accommodation. The travelling is by first-class special train throughout and the accommodation is the very best which each place affords. Full particulars of this year's trip are not yet available but this, at any rate, is certain. The rendezvous is at Luchon on Sept. 1st, the stations to be visited are interesting and important in the highest degree, the district surpasses in beauty even that of the Alps, and last, but not least, visitors from this country will meet with a welcome the cordiality of which will surprise and delight them. Inquiries, which may be in English, should be addressed to Dr. Carron de la Carrière, 2, Rue Lincoln, Paris.

MODERN IMPROVEMENTS IN THE HYGIENIC CONDITIONS OF INDUSTRIAL OCCUPATIONS.—At a meeting of the Royal Statistical Society held on May 16th a paper, entitled "The Effect, as shown by Statistics, of British Statutory Regulations directed to the Improvement of the Hygienic Conditions of Industrial Occupations," was read by Mr. Leonard Ward, H.M. Inspector of Factories. The paper opened with a brief historical survey of the hygienic clauses of the Factory and Workshop Acts and the Coal and Metalliferous Mines Acts, and proceeded to review the well-known unhealthy conditions and absence of hygienic surroundings attending the employment of adults and children in factories and mines which obtained prior to, and during the early stages of, industrial legislation. The effect of progressive legislation in ameliorating the insanitary conditions was next considered from three different, but closely related, standpoints—namely, the effect on (1) the mortality-rates; (2) the "sickness experience"; and (3) the physique of the operatives employed in the several typical occupations under review. The steady improvement which has taken place in the conditions of employment in the cotton manufacture during a century of statutory sanitary reform was traced. The decline in the death-rates from phthisis and respiratory diseases in certain typical "cotton towns" was shown to be largely due to the enforcement of the hygienic clauses of the more recent Factory Acts, especially the Cotton Cloth Factories Act, 1889. Comparisons on the bases of weight and height were made between factory children of 1833 and factory children of 1873 and between non-factory children of 1833 and non-factory children of 1873. The results led to the inference that there had been a relative retardation of growth in children employed in textile factories, and that one effect of factory legislation had been to prevent undue deterioration in this class of operative. In the sections relating to the pottery, white lead, and lucifer match industries it was shown that substantial improvement in the shape of less lead and phosphorus poisoning had resulted from the enforcement of special sanitary measures. With regard to the health of coal and ironstone miners the evidence proved that 50 years of statutory regulations had produced such salutary results that the mortality of coal-miners of the present day only slightly exceeds that of agriculturists. Mr. Ward estimated that more than 15,000 lives had been saved during the last 50 years solely by the prevention of explosions of fire-damp or coal-dust, and that this had been mainly brought about by the provision of "adequate ventilation" as required by the Coal Mines Act of 1855 and subsequent Acts.

The Late Dr. J. E. Dutton: An Impressive Funeral.—A mail which has arrived at Liverpool from the Congo confirmed the news of the sad death of Dr. J. E. Dutton, of the Congo expedition of the Liverpool School of Tropical Medicine, on Feb. 27th. His death was the direct result of overwork. He persisted in working during his convalescence *from a severe attack of spirillum fever* which he was at the time closely investigating. He was suddenly taken ill and after four days of unconsciousness died in the presence of Dr. J. L. Todd and Dr. Heiburg, other members of the expedition. The esteem in which he was held by the natives was very strikingly displayed at the funeral, which took place on Feb. 28th. A simple cross was placed on the coffin and the officers of the post laid a palm branch on it. There were 12 bearers, all native sergeants, and the coffin was preceded by a bugle band and followed by Dr. Todd, Dr. Heiburg, Commandant Verdick, and all the white officers, together with soldiers and natives, the latter saluting before joining in the funeral procession. Over 1000 people were present to see the coffin pass to its resting place and the Burial Service was read by Dr. Todd.

Volunteer Ambulance School of Instruction.—The annual banquet of the staff and members of the school took place at the Trocadéro Restaurant on May 18th, Surgeon-Colonel P. B. Giles, 30th Field Army Brigade, Senior Medical Officer, being in the chair. Colonel Giles, in responding for the school, said that the school was very prosperous and that nearly 700 medical officers from all parts of the empire had passed through it as well as some 4000 stretcher bearers. He recognised that the prosperity and the efficiency were due to the loyalty of the instructors, the officers, and the non-commissioned officers. He really thought that the new examination for promotion would be beneficial as it required further study and a more intimate acquaintance with the interior economy of the Royal Army Medical Corps, and that the examination was popular with medical officers was evident, for at the present moment the school had a large class preparing for it. The chief difficulty to be faced was the dearth of officers entering the service and he felt certain from his knowledge of affairs that the regulation course at Aldershot or elsewhere was an impossibility; not 1 per cent. of officers could afford the time required to attend. He thought and hoped that as there was a member of the Advisory Board present the Government might see its way to issue allowances to officers attending the school provided that they attended regularly and passed the required examination. Such a concession would induce a greater number to join the service which at the present moment was imperilled wholly and solely by reason that the Government did not hold out sufficient inducement for well qualified men to join. He was glad to read in a recent speech of the Director-General that he intended to bring the Volunteer Medical Service more into line with the Royal Army Medical Corps and so obtain a higher state of efficiency from the senior medical officers; intelligent and liberal treatment of volunteer medical officers would create an efficient corps to supplement the Royal Army Medical Corps in time of national danger. During the late war had the Volunteer Medical Service been, as it should and very easily could be, made efficient then there would have been officers and men sufficiently trained to supplement the Royal Army Medical Corps and no need for the employment of civilians. During the evening the string band of the Cadet Battalion of the Royal Fusiliers gave an excellent selection of music. The arrangements for the banquet were made by the mess president, Surgeon-Captain E. M. Callender, and a very enjoyable evening was spent.

On July 17th next, says the *Russ*, the Pan-Russian Dentists' Congress will open in St. Petersburg.

Seamen's Hospital, Cardiff.—Sir W. T. Lewis has contributed £1000 to endow a bed, to be named "The Lady Lewis Bed," at the new Seamen's Hospital, Cardiff.

Presentation to a Medical Practitioner.—At the annual meeting of the Padstow (Cornwall) branch of the St. John Ambulance Association, Mr. Richard Palk Griffin, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., was presented with a cabinet containing cigars in appreciation of his services as honorary instructor.

Dawlish Cottage Hospital.—Mrs. Nosworthy of Dawlish, in Devonshire, has given £1200 to defray the cost of the reconstruction and enlargement of the Dawlish Cottage Hospital and the High Sheriff of Devon (Mr. Bayldon) has promised £120 for the heating of the new portion of the building.

Donations and Bequests.—Mrs. Caroline Judith Stanier has by will bequeathed £1000 to the Salop General Infirmary and £1000 to the North Staffordshire Infirmary.—The British Home and Hospital for Incurables, Streatham, has received a gift of 10,000 shillings from Miss Thomas of London towards the 200,000 shillings for which appeal is being made.—The late Mr. James Donald, manufacturing chemist, of Glasgow, whose will has just been proved at over £106,000, left amongst other bequests to public institutions £3000 each to the three Glasgow infirmaries—the Royal, the Western, and the Victoria.

Homes for Inebriates Association.—The report of this association, of which Sir Charles Cameron, Bart., M.P., is the president, for the year 1904–05, together with the twenty-first annual report of the Dalrymple Home at Rickmansworth, has just been published by Mr. H. K. Lewis, Gower-street, London, W.C. Though the number of patients presenting themselves for treatment was less than last year and financially the home accounts show a loss on the year's working of £74 10*s*. the work of the association has been satisfactory and the valuable services of Mr. F. S. D. Hogg, the medical superintendent of the Dalrymple Home, and his staff are cordially acknowledged by the committee of management. Mr. Hogg, in his report, states that during the year eight patients were admitted under the provisions of the Inebriates Acts and 23 as private patients, 31 in all.

[illegible]

inebriate st[illegible]
become mor[illegible]
ment frame[illegible]
are not law breakers.

34 patients have been discharged during the year and 16 remain under treatment. Adding this number, 16, to the total recorded discharges the result, 771, is the number of patients admitted since the home was opened. Donations and promises of annual subscriptions will be received by the chairman, the Rev. Canon Duckworth, D.D., 5, Abbey-road, St. John's Wood, London, N.W., and the secretary, Mr. John Swinford Francis, Court-chambers, 173, Marylebone-road, London, W. Cheques may be crossed "London and County Bank, Paddington Branch."

Central Midwives Board.—A meeting of the Central Midwives Board was held at 6, Suffolk-street, Pall Mall, London, on May 19th, Dr. F. H. Champneys being in the chair. It was reported to the Board that a certain midwife who had been admitted to the roll was not a person of good character. According to a newspaper cutting received this midwife was concerned in a police-court charge in an assault case connected with a man with whom she was stated to be living, though not married to him. It did not appear to the Board that such a report of immorality could be acted upon by the Board. In the case, however, of another woman who applied to be placed on the roll as a midwife the Board refused the application in consequence of a communication received from the clerk of the county council in whose district the woman resided informing the Board that the woman had been convicted of being drunk on three successive days in one week. The Board discussed certain applications from medical men as teachers of midwifery under Rule C 1 (3). Mr. E. Parker Young urgently insisted on the necessity of the Board recognising general practitioners as teachers of midwifery because, by refusing to sanction many of these applicants as teachers, a great injustice was done to women desirous of being trained as midwives. These general practitioners who were refused the sanction of the Board as teachers of midwifery had been instructing midwives in midwifery for many years. The localities where these general practitioners gave lectures were at some distance from institutions for training midwives. It was unfair to these poor women to make them travel in some cases more than 30 miles to attend lectures on midwifery, when by sanctioning general practitioners as teachers any such hardship could be avoided. General practitioners were perfectly competent to teach these women and it was the duty of the Board to make the Act work as easily as possible for women training as midwives. After Dr. Champneys had said that there had not been any boycotting of general practitioners, Mr. Young submitted a motion that certain general practitioners should be recognised as teachers of midwifery. The motion, however, was not adopted by the Board.

BRISTOL LUNATIC ASYLUM.—Dr. J. V. Blachford, the medical superintendent, in his annual report to the visiting committee of this institution for 1904 states that the percentage of recoveries on the admissions, excluding transfer cases, was 42·59. 112 patients were discharged recovered during the year, 10 being transferred to other asylums. There were 110 deaths, the death-rate on the average number of resident patients being 12·02 per cent.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Bubonic Plague in India and Scotland.

Mr. SEYMOUR ORMSBY-GORE has given notice of his desire to call attention to the increase of bubonic plague in India and to propose a motion and Mr. WYLIE has put down a similar motion as to the outbreak of plague at Leith and other parts of Scotland. No day has been fixed for either motion.

HOUSE OF COMMONS.

THURSDAY, MAY 18TH.

THE LANCET *and Vaccination.*

Sir JOHN ROLLESTON asked the President of the Local Government Board whether he was aware that the recently published opinions of Dr. S. Monckton Copeman and of the Commissioners appointed by THE LANCET in 1900 and 1902 to examine the various lymphs on sale in this country, supported the view that large marks were not an evidence of efficient vaccination, and that small marks were not an evidence of inefficient vaccination; and that the same authorities had shown that in consequence of the modern methods of vaccination it was possible to produce the Board's stipulated area of vesiculation—viz., not less than half a square inch—without leaving anything like a corresponding area of marks; and whether he proposed to take any steps to amend the Board's Vaccination Order of 1898 so as to make it more consistent with the latest medical evidence on these points.—Mr. GERALD BALFOUR answered: Dr. Copeman informs me that in his opinion large scars are not necessarily evidence of efficient vaccination and small scars are not in themselves evidence of inefficient vaccination, but that usually the area of the scar corresponds fairly closely with that of the vesicle which preceded it. These opinions do not, as I am advised, render it necessary or desirable to amend the Vaccination Order, 1898, which does not make the area of the scar a criterion of successful vaccination.

Disinfecting Clothing of Small-pox Patients.

Mr. DONAL SULLIVAN asked the Chief Secretary for Ireland whether his attention had been called to the fact that the Irish Local Government Board now stated that the disinfecting chamber erected in 1895 in the Athlone workhouse under the system known as Dr. Scott's Patent Hot Air Disinfecting Chamber, and approved by the Board, was useless and why the Board sanctioned the necessary loan.—Mr. LONG replied: The Board has not stated that this disinfecting chamber is useless but in reply to the guardians' inquiry whether it was sufficient for the purpose of disinfecting the clothing of small-pox patients it stated that such a chamber is not to be depended upon and that disinfection after small-pox requires special efficiency. The Board understands that disinfection by hot air is rapidly falling into disuse. Experience has shown that such disinfection is not as efficient as disinfection by steam, as the hot air does not penetrate the clothing so thoroughly as steam. When sanctioning a loan in 1895 the Board imposed no conditions upon the guardians as to the description of disinfector which they should obtain.

Blood Poisoning in an Infirmary.

Mr. SLOAN asked the Chief Secretary for Ireland whether he was aware that cases of blood poisoning occurred in the Cootehill union infirmary in January, 1904, alleged by the medical officer and inspector to be due to rotten floors and want of sanitary accommodation; and whether, [illegible] made on behalf of the seven electoral [illegible] necessary alterations to be made and tha[illegible] the Local Government Board to confer with the board of guardians, he could say what action, if any, had been taken in the matter.—Mr. LONG replied: Cases of septicæmia occurred in this workhouse in January, 1904. The medical officer was of opinion that the germs of the disease were in the floors and possibly in the walls. The Local Government Board's inspector inquired into the matter and reported that it was difficult to find the direct and definite cause of the outbreak, as there are several ways in which infection of the kind could be conveyed. He advised the guardians to make certain alterations and thereupon they decided to obtain an estimate of the cost. No further action has, however, been taken by the guardians but the new board will come into office next month and the Local Government Board will urge it to take the matter in hand.

MONDAY, MAY 22ND.

Insanitary Mattresses and Disease.

Mr. FULLER asked the President of the Local Government Board whether his attention had been drawn to the insanitary condition of certain cheaper kinds of flock used in the manufacture of cheap mattresses; and whether he would take steps, by legislation or otherwise, for the prevention of the spread of infectious disease arising from the use of insanitary and unwashed materials.—Mr. GERALD BALFOUR said: My attention has been drawn to the sale and use of unwashed flock for bedding and other purposes. The compulsory cleansing of the materials referred to could not be generally secured under the existing law. The point has been noted for consideration but I cannot at present hold out any prospect of legislation on the subject.

Evasions of the Medical and Dental Acts.

Sir JOHN BATTY TUKE asked the Home Secretary whether he had received an opinion from the Law Officers of the Crown concerning evasions of the Medical Acts and of the Dentists Act under the provisions of the Companies Acts; and, if so, whether he would communicate it to the House.—Mr. AKERS-DOUGLAS said: The Board of Trade has received an opinion from the Law Officers, but I am unable to accede to my honourable friend's request, as such opinions are treated as confidential.

TUESDAY, MAY 23RD.

The Prevention of Malarial Diseases.

Sir MANCHERJEE BHOWNAGGREE asked the Secretary of State for India whether he was aware that the efforts of the Mexican Government and the Superior Board of Health of Mexico to stamp out yellow fever and all malarial diseases by exterminating the mosquito by the adoption of certain scientific methods had met with considerable success; and whether, having regard to the fact that malarial fevers were constantly prevailing in parts of India, he would cause inquiries to be made in connexion with the Mexico experiment with the object of giving it a trial in India.—Mr. BRODRICK replied: I have seen a pamphlet on the subject by the Superior Board of Health at Mexico and propose to send a copy of it to the Government of India. Experiments of a somewhat similar kind have for some time past been in progress in India and the experts conducting them are doubtless aware of what is being done in the same direction in other parts of the world.

The Medica[illegible] and Denta[illegible] Registers.

Mr. WEIR asked the Home Secretary whether he could state how many medical and dental practitioners had been struck off the Register during the last ten years for infamous or disgraceful conduct; and in how many instances the names of practitioners had been restored to the Register during the same period.—Mr. [illegible] I have asked the General Medical Counc[illegible] information and when it is received I shall be happy to [illegible] it to the honourable Member.

SELECT COMMITTEE ON REGISTRATION OF NURSES.

The Select Committee of the House of Commons which is considering the expediency of the registration of nurses heard further evidence on May 18th.

Sir Victor Horsley and Dr. Langley Browne appeared as representatives of the British Medical Association and sat together at the witnesses' table.

Replying to the CHAIRMAN (Mr. H. J. TENNANT), Sir VICTOR HORSLEY said that the British Medical Association consisted of close upon 20,000 medical practitioners and it was therefore in their opinion, the only voice of the medical professi[illegible] the corporate bodies did not [illegible] the councils of those bodies—such as the College of Physicians. He was chairman of the representative meeting of the Association at Oxford last year. This meeting consisted of delegates chosen by each division of the Association. The following resolution was passed at the Oxford meeting:—"This meeting approves of the principle of the registration of nurses; and further resolves that the foregoing resolution be transmitted to the Select Committee." The representative meeting did not in any way enter upon the provisions of the two Bills now before Parliament, keeping an absolutely open mind as to details of legislation that might be proposed. The resolution was carried *nemine contradicente*, there being no opposition as far as he could recollect. The vote was taken by a show of hands. About 154 members were at the meeting out of a possible attendance of 200. In the discussion some delegates stated that they were not directly instructed by their divisions to vote on the point but they had full powers, the matter having been previously referred to their divisions. As far as he could remember one or two critical speeches were made against the resolution. He had received notice that at the Leicester meeting in July this year one division would appear in opposition to this vote. Practically all the members present at last year's meeting supported the resolution and the feeling was so clear that he did not think this further resolution at the Leicester meeting would have any chance of being carried. The matter of registration of nurses and the principle of it had been before the British Medical Association for a very considerable time about 20 years altogether. The first vote that was taken in a public meeting of the Association occurred ten years ago on July 30th, 1895. At the general meeting of the Association held in sub-committee.

What do you say about the s

perience. He had often known partially trained nurses pose as perfectly trained nurses and receive the same remuneration from patients.

be a penal clause punishing persons practising nursing for gain and illegally entering into competition with a person trained and registered. That was undoubtedly the idea in the minds of the British Medical Association. He would, however, regard as satisfactory a system of voluntary registration if managed by the State.

Mr. C. HOBHOUSE: Do you agree that nobody is to be allowed to nurse for gain unless after three years' training and registering?—Dr. LANGLEY BROWNE: Quite. I think that is the idea. Of course, it does not mean that one woman must not go to nurse another but that she ought not to be allowed to follow the profession of a nurse.

Sir VICTOR HORSLEY. The word in the Midwives Act is "habitually" As to the composition of the Central Board the opinion of the Medico-Political Committee was that the proposals in the two Bills were extravagant and that the boards therein proposed

practitioners of the country.

The committee *adjourned.*

Further evidence was taken on Tuesday, May 23rd.

Mrs. C. HOBHOUSE was first called. She stated that she had been on the committee of the Rural Nursing Association of Wiltshire since 1893 and had been treasurer, secretary, and chairman successively of that body. There were 15 nurses on the staff. Approximately 1000 nurses had passed through the hands of the committee, some for rural purposes and some for colonial work. She hoped that any Act which dealt with registration would not overlook the consideration of nurses fit to nurse the poor in the rural districts.

The CHAIRMAN: I think the committee would certainly bear that in mind.

WITNESS, continuing, said that the proportion of trained rural nurses was about 1 in 8. She had been satisfied with the manner in which they had discharged their duties. As a rule in rural districts the nursing required was of a simple character, the acute cases going to hospitals. Therefore, in the first place the rural district could not support the trained nurse financially and, in the second place, the best class of highly trained nurses would not remain because of the lack of acute cases.

The CHAIRMAN: If a Registration Act were passed similar to the Midwives Act you would be rather apprehensive that the partially trained nurse would not be able to nurse as she does now?

WITNESS: It depends on the lines which registration follows. It may be done in such a way as to make it extremely difficult to get probationers. Continuing, Mrs. Hobhouse said she thought that the best course to pursue with regard to these partially trained nurses was probably that suggested in the resolution of the British Medical Association. If it were possible for rural nurses to get certificates showing they were capable of doing a certain class of nursing and thereby work up to a higher grade later she thought it would be extremely advantageous. Her experience was that there was a great shortage of highly trained nurses in all parts of England. She thought the reason was largely that the training certificate usually approved by most committees was that of the London hospitals. There were not enough nurses turned out in London to meet the demands and therefore nurses trained in the provinces were also forthcoming. The training in many of the provincial hospitals was quite as good, if not better, than in many London hospitals, but broadly speaking in the public mind it was not so.

The CHAIRMAN: Would it not help the situation to have a system of registration?

WITNESS: It depends on how it is done. If it is made too stringent the shortage would be intensified. Hospitals might coöperate for the purpose and so level up the training in hospitals.

The CHAIRMAN: If registration were made reasonable you would welcome it?

WITNESS replied that if it were made reasonable it would be rather helpful. It might tend to give the provincial hospitals a status they did not now hold, although they deserved it.

The CHAIRMAN: How would you classify the nurses to be employed in the rural districts?

WITNESS: Primarily they would be obstetrical.

The CHAIRMAN: Would there not be some overlapping? Would they come under the Midwives Act?

WITNESS: Certainly.

The CHAIRMAN: Would you have them undergo two examinations?

WITNESS: I do not think you could make them pass both.

The CHAIRMAN: A nurse certified by the Midwives Board would not be allowed to nurse cases of pneumonia and diphtheria?

WITNESS: It would entirely depend on her knowledge.

Continuing, Mrs. HOBHOUSE said it would be most harmful to make it a penal offence for any person to nurse for gain unless she obtained a certificate.

As regarded the question of n[illegible] medical men. WITNESS said she h[illegible] men feared such competition. In [illegible] ground for that fear, but generally speaking there was not. It depended very much on the status of the medical man, whether he had been established for some years or had only just started. In the latter case people were apt to send for the nurse.

WITNESS thought some scheme of registration would be helpful but she wished to see something more definite before committing herself to any scheme. In the first place, the examination should be based upon a curriculum for training. There might be a minimum time limit for the highly-trained nurse of two years, although she did not think it was necessary. Another essential feature was that the training should not be in one hospital and hospitals should have the power of co-operation for the purpose. The mere fact of registration should not be regarded as a guarantee of a nurse's character. She would also have examinations based on a curriculum for the less highly-trained nurses who were quite able to pass an examination.

Replying to Mr. DOUGLAS, WITNESS said if a minimum training could be arranged for rural nurses so as to make it a first step in the nursing profession it would assist rural nursing considerably. The fact of other nurses having their certificates recognised by the State would be detrimental to the supply of rural nurses because they had to look forward after their time of service in the association for promotion and the tendency would be for every sort of appointment to go to registered nurses. She thought the disadvantage would be removed if hospitals were empowered to recognise in some degree as an instalment of training the work done outside. If nursing associations were allowed to certify the first year of a three years' curriculum the objection would be removed.

Questioned by Dr. C. F. HUTCHINSON, WITNESS thought that the standard of [illegible] ably improved during the [illegible] classification or two grad[illegible]

Dr. W. G. DICKINSON was next called. He said he had been in practice in London for many years. He considered the registration of nurses was unnecessary because the present arrangements were quite satisfactory. If the wealthy had bad nurses it was their own fault, and if the poor had bad nurses it was the fault of the institutions that sent them out. Compulsory registration of all nurses was quite out of the question. The only difficulty he had in regard to nurses was due to his own fault. He could recall several unsatisfactory nurses whom he took on their own recommendation instead of applying to a suitable body or hospital. He would be in favour of registering nurses' homes and institutions. He thought the scheme of registration would fail financially because the nurses would not register in the numbers that had been estimated.

Replying to Mr. HOBHOUSE, WITNESS said a great bulk of the members never took part in the proceedings of the British Medical Association and it was very easy to pass resolutions in which members were not particularly interested.

Mr. HOBHOUSE: Is this regarded as a burning question among medical people?

WITNESS: I should not say so.

Asked if he had anything to add WITNESS said it was stated the other day that the Incorporated Medical Practitioners' Society had passed a resolution in favour of the registration of nurses. That was the case, but the result was that a large number of members decided to resign and he believed the resolution was eventually rescinded.

Miss KENT, who said she had been engaged in nursing in the provinces and London for 13 years and was at one time night superintendent in a Dudley hospital, was called. She regarded registration as being most essential. It would safeguard the public and raise the status of the profession. A number of small nursing institutions were springing up all over the country which charged as much as 25 per cent. on the earnings of the nurses. They were managed by people who had no knowledge of, or sympathy with, nurses. They oppressed and sweated nurses.

The committee then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BLAKISTON, ARTHUR ALEX., M.R.C.S., L.S.A., has been appointed Deputy Medical Officer for the Third District of the Wells (Somerset) Union.

BRIDGES, E. CHITTENDEN, M.D., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Anæsthetist to the Victoria Hospital for Children, Chelsea.

CUNNING, JOSEPH, M.B., B S. Melb., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Victoria Hospital for Children, Chelsea.

HEATON, CHARLES, M.D. Brux., M.R.C.S., L.R.C.P., has been appointed Honorary Assistant Visiting Surgeon to the Royal Sea-Bathing Hospital, Margate.

HOOPER, GEORGE HENRY JAMES, M.D. Lond., L.R.C.P. Lond., M.R.C.S., J.P., has been appointed Chairman of the Sutton (Surrey) District Council.

HOOPER, Miss E., M.B., B.S. Lond., has been appointed Resident Clinical Assistant to the Hospital for Women and Children, Leeds.

JOLLIE, P. OSWALD, L.R.C.P. & S. Edin., L.F.P. & S. Glasg., has been appointed Medical Officer and Poor-law Vaccinator for Colmonell, Ayrshire.

LOCK, JOHN LEWIS, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Medical Officer to the Infirmary of the Uxbridge Union.

LYLE, H. WILLOUGHBY, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to the Royal Ear Hospital, Soho, and Consulting Ophthalmic Surgeon to the Beckenham Cottage Hospital.

SARGENT, PERCY, M.A., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Surgeon to Out-patients, Victoria Hospital for Children, Chelsea.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BETHLEM HOSPITAL.—Two Resident House Physicians, unmarried, for six months. Honorarium at rate of £25 per quarter, with board lodging, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

TOTTENHAM HOSPITAL, London, N.—Casualty Officer for six months. Salary at rate of £40 per annum, with residence, board, and [illegible]

[illegible]LUM.—Second Assistant Medical [illegible] £150 per annum, with board, [illegible]

[illegible] FOR POORER CONSUMPTIVES.—[illegible]ed. Salary £200, rising to £300.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at New Ross, in the county of Wexford.

Births, Marriages, and Deaths.

BIRTHS.

BATEMAN.—On May 19th, at Avenue road, Regent's park, N.W., the wife of A. George Bateman, M.B., C.M., of a daughter

CARRUTHERS.—On May 11th, at Manor-house, Batheaston, the residence of her father, the wife of Alan Eskrigge Carruthers, M.A., M.B. Cantab., of a daughter.

FISH.—On May 20th, at Llanbedr Hall, Ruthin, North Wales, the wife of Cecil E. Fish, B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., of a son.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE STORY OF THE ST. HELENS HOSPITAL.

ACCOMPANYING the annual report of the St. Helens Hospital for the year 1904 is an illustrated pamphlet dedicated to the memory of "Doctor Herbert Knowles," giving the story of that useful institution *compiled from articles which have appeared in the public press.* 35 years ago there was no hospital in St. Helens, though the need for some place where the sick poor could be adequately treated was felt by many. On the suggestion of Mr. A. G. Kurtz, Mr. J. Fenwick Allen sought out a suitable building which within three months was transformed into a hospital with four beds. The first patient was a farm labourer, the conditions of his admission being the payment of a shilling a day and that his own medical man should attend him. Mr. Allen became the first honorary secretary. How the hospital gradually grew to its present size with accommodation for 100 patients and with everything necessary for their proper treatment and comfort and the building of a nurses' home is sympathetically told in the pamphlet under notice, which is embellished with portraits of many prominent individuals connected with the history of the hospital. The illustrations [illegible] hospital [illegible] cost of [illegible] £22,500 [illegible] large subscriptions and by the generosity of working men, leaving a balance of nearly £4000 still to be provided. The management of this institution seems to be equally satisfactory to both medical men and their patients from the account given of the working of the hospital in the annual report, though to our mind the absence of a resident medical officer is not to be regarded as a safe condition of things unless there is some stipulation that cases of great emergency will not be received. The conditions of admission are aimed at solving some of the problems of hospital economy and are worth studying I. Every patient must contribute one shilling a day towards the funds of the hospital during the time he remains in, or have been a regular subscriber of one penny per week (or one halfpenny in the case of women and children) previous to the commencement of the sickness or date of the accident which causes him to seek admission. *II. At the works where a penny-a-week subscription* is made the workmen will be allowed the extra advantage of the admission of their wives and children under 13 years of age, free of charge, provided there be not more than one of a family in the hospital at a time. III. Accidents are admitted at all times. IV. Every patient selects and pays for his own medical man. V. Cases of sickness must be recommended by a medical man as suitable. VI. Patients admitted to the hospital as penny-a-week subscribers, or as members of the family of any such subscriber, will be sent to the Southport Convalescent Hospital, the Devonshire Hospital, Buxton, and the Eye and Ear Infirmary, Liverpool, free of charge to them, whenever the medical attendant considers it desirable that they should be sent there. VII. Patients for the Eye and Ear Infirmary, Liverpool, must procure certificates, one from a medical man and another from the works where they pay their subscriptions, and attend at *the hospital for instructions. The* permission to the patient to choose his own medical man, which clearly follows on the condition that he should pay him, puts the hospital at once in a different position from that occupied by the ordinary charitable institution. But is not the danger likely to occur that the patient, though assisted by charity and attended by medical men at the lowest possible cost, may believe that he is only receiving a due return for his pence?

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

[illegible] for your opinion on the following [illegible] B is also practising in a village [illegible]n in practice about 19 years. B has been in practice about three years. A has a patient whom he used to attend before B came to the neighbourhood but on B's arrival the patient employs B and soon the patient asks A to meet B in consultation, which he does on two occasions. In a few weeks after the second consultation the patient sends to A saying he has finished with B and wants A to attend him, saying at the same time that if A refuses he is going to employ another medical man from the town. Now is A correct in accepting his old patient again as his ordinary medical man? Both A and B are general practitioners.

I am, Sirs, yours faithfully,

May 22nd, 1905. M.D.

*** The point upon which our correspondent invites our opinion is practically the same as that with which we dealt in our issues of April 29th, p. 1174, and May 6th, p. 1243, and he will find our opinion stated there. [illegible]ight [illegible] to change his [illegible] has [illegible] given up wish [illegible] the [illegible] patient will c[illegible]rise. [illegible] We therefore [illegible]

HOW A CHOLERA EPIDEMIC WAS STARTED.

Major Sykes. British Consul at Kerman, writes in his report for 1904-05: "For the first time since my residence in Kerman cholera broke out. A pilgrim returned from Meshed and died from cholera a few miles out of Kerman. His body was washed in running water and his clothes were sent into Kerman and sold, thus starting the epidemic. The entire Persian official community ran away, followed by everyone who could procure a mount, and as a result the villages were immediately affected. Business was at an utter standstill and the only bright side was the heroic labours of the medical men of the Church Missionary Society who fought the epidemic single-handed. Fortunately, the cold weather was near and by the end of December, after having run its course for about two months, with a loss of life aggregating perhaps 500, the epidemic ceased. Two salient points were brought out—viz., the necessity of providing properly trained Persian doctors and also the equal necessity of training the people to obey a few simple regulations for the preservation of their health."

THE BORIC ACID OF TUSCANY.

IN the course of a special report on the mineral wealth of the provinces of Siena and Grosseto, Mr. Chapman, the British Consul-General in Italy, mentions that a remarkable natural phenomena occurring in Tuscany are the "soffioni," or "blowers," which are to be seen in the neighbourhood of Pomarance. These emit steam and water at a very high temperature, as much as 257° F. it is said, with a noise similar to that of steam escaping from a boiler under very high pressure. In the year 1779 two savants of the period, Mascagni and Hoefer, in the course of their investigations into the nature of the curious phenomena, discovered that boric acid was present in the waters ejected by the "blowers." At the time the discovery was considered to have merely a scientific interest, but in the year 1818 it occurred to certain speculators, with M. Larderel, a native of France, at their head, that the recovery of the boric acid might be a profitable venture and works for this purpose were established on a small and tentative scale. To effect the evaporation of the waters and to recover the boric acid present artificial heat was adopted. But the process, for this reason, was not a success, the cost of fuel in a district bare of forests was found to be excessive. In the year 1825 the works and concessions were taken over entirely by M. Larderel and they have since remained in the same family. The financial success of this undertaking began to date from 1827, when M. Larderel solved the problem by applying the natural heat of the sources to the evaporation of the waters collected in boilers or tanks. This industry enjoyed remarkable prosperity during a period of about 40 years when both the producers and the parties to whom they sold their output for a term of years obtained practically their own prices. But the discovery of borax in California and Chili and of boracite on the borders of the Sea of Marmora brought about a great change in this respect. The Tuscan industry, however, holds its own and with an increasing consumption of this substance all over the world the outlook is more favourable now than it has been for some years past. The production of boric acid in Tuscany averages about 2700 tons per annum of the approximate value of £54,000.

"CHINOSOL COMPRESSED TABLETS."

IN our analytical notices last week it was incorrectly stated that the chinosol tablets mentioned contained five *grammes* of the pure powder. The quantity should have been reported as five *grains*.

AN OLD LANCET CASE.

To the Editors of THE LANCET.

SIRS,—I have recently come across an old silver lancet case which, so far as can be judged from the somewhat obliterated hall-marks, is of the date 1795-96, and perhaps Sheffield was the assay office. It bears on it the initials, doubtless of its original owner, "C.F.S." It contains two lancets, and the chief reason why I venture to trouble you with this communication is that I am desirous of knowing whether these lancets are contemporary with the case or of modern date. One of them bears as the name of the makers "Savigny & Co." and the other "Pratt." Perhaps some of your readers can kindly give me information as to these makers. I do not see the names in the list of surgical instrument makers in the Post Office Directory but, of course, that does not prove that the firms are not now in existence.

I am, Sirs, yours faithfully,

May 24th, 1905. PROVENANCE.

A. G.—How an "overworked doctor in hidden-away districts" comes to "want keeping up to his duty" passes our understanding. The man who already does more work than he ought cannot need spurring to do more; at any rate, no wise person would suggest the treatment. Patients with typhoid fever who are in poor circumstances can in London very seldom be nursed in their own homes.

Lancelot.—The regulations concerning the carriage of medicine by rural postmen are laid down in Clause 21 of the general regulations published in the Postal Guide. The Postmaster-General can withdraw the permission either generally or in any particular case, but we have no knowledge of its having been withdrawn so far.

General Practitioner.—Our correspondent sends us a report of what we presume was a public meeting and the matter to which he draws attention formed a portion of the report read at the meeting in question. In these circumstances we do not consider that the question of advertising can arise.

Ternuh.—From the information which our correspondent has sent us we do not think that there would be any objection to the marriage of the children in question, presuming, of course, that they exhibit no mental instability as they grow up.

B.Sc. would like to be referred to any book containing a clear account of the different theories of the numerous writers on Evolution since Darwin, also to the works of Mendel, Weismann, Beard, Bateson, and Weldon.

B. S.—The preparation mentioned by our correspondent contains bromides. These salts are, of course, very commonly given for epilepsy but they should certainly not be so given except under medical supervision.

Hector.—The same precaution should be taken with regard to diphtheria as with other infectious diseases.

W.—Our correspondent will find our opinion of Liquozone at p. 1309 of THE LANCET of May 13th.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.).

TUESDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.).

WEDNESDAY (31st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.) Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Mr. Ballance: Surgery of the Nervous System.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to *the Agent to whom the subscription is paid, and not to* THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

Discours

SUR

LES CONDITIONS GÉNÉRALES DES ÉTUDES MÉDICALES ET DE L'ASSISTANCE PUBLIQUE À PARIS,

À PROPOS DU VOYAGE DES MÉDECINS BRITANNIQUES.

PAR LE DOCTEUR LUCAS-CHAMPIONNIÈRE,
CHIRURGIEN DE L'HÔTEL-DIEU; MEMBRE DE L'ACADÉMIE DE MÉDECINE.

LE voyage de nos confrères Britanniques à Paris a été un grand succès pour nous. Tous ceux d'entre nous qui avions été à Londres en Octobre avions conservé de l'accueil de nos hôtes un souvenir si parfait que nous avions à cœur de leur en témoigner notre reconnaissance et de leur montrer qu'à Paris nous ne manquions pas de faits et d'établissements scientifiques dignes de leur attention et bien prêts pour leur examen. Nous avons eu une première satisfaction: nos confrères sont venus nombreux. Les maitres les plus eminents ont bien voulu se mettre à leur tête. Ils n'ont point redouté la fatigue, se sont mêlés à toutes les fêtes et ont donné par leur parole un éclat singulier à toutes nos manifestations scientifiques.

Dès son arrivée sur la terre Française Sir Dyce Duckworth nous avait adressé en un Français correct et élégant un aimable salut au nom de tous les confrères Britanniques. Sir William Broadbent chaque jour, et plusieurs fois par jour, avec la bienveillance et la finesse d'esprit qui le caractérisent a pris la parole au nom de tous ceux qu'il présidait. Le Professeur Clifford Allbutt à la Sorbonne comme au banquet en un Français bien clair et plein d'érudition nous a montré combien il avait su conserver de la science Française qu'il était venu étudier. En Français aussi le Professeur Pye-Smith nous a parlé. Il a même à l'Hotel-Dieu rappelé ses souvenirs de Trousseau qui ont été au cœur de tous les élèves de ce grand maitre. En Français encore les deux discours fort remarquables prononcés sur la tombe de Pasteur par le Docteur Kingston Fowler, doyen de la Faculté de Médecine de l'Université de Londres, et par le Docteur Augustus Waller, chef des Laboratoires de l'Université de Londres. Tous deux ont été remarquables par la facilité de leur élocution, par la perfection de leur langage et par la très juste et vraiment éloquente appréciation de l'œuvre de notre grand Pasteur. J'ai été personnellement très enchanté d'entendre le Professeur Waller émettre cette pensée très philosophique sur laquelle j'ai pour ma part insisté il y a quelques années: "Nous sommes encore trop près de Pasteur pour juger l'œuvre et le savant. Il faut le recul du temps pour apprécier justement les découvertes qui ont transformé la science actuelle et qui auront sur la science future une répercussion que nous ne pouvons soupçonner." En Français encore un discours du Docteur Georges Ogilvie, qui nous avait déjà habitués à Londres à sa bienveillance d'une part et d'autre part à sa parfaite connaissance de notre langue, de nos habitudes, de notre esthétique et même de notre quartier latin.

Si les discours en Anglais ont été moins bien compris de la masse des médecins Français ils n'ont pas été moins bienvenus ceux qu'ont prononcé Sir William Macewen, l'un des chirurgiens dont les travaux sur les maladies et opérations des os sont les mieux connus en France; le Surgeon-General Keogh, qui nous a parlé de nos grands maitres militaires et de leur fraternité d'armes avec les chirurgiens Anglais, en chirurgien erudit; et enfin M. Lynn Thomas.

Nous sommes encore tout particulièrement reconnaissants aux dames Anglaises d'être venues nombreuses. Elles ont donné aux fêtes un grand éclat. Puis mêlées aux dames Françaises qui les ont reçues, elles nous ont donné la preuve que si une union scientifique entre les peuples est d'importance capitale, l'union morale, intellectuelle et familiale par les dames donne à l'union par la science tout le charme qui lui aurait manqué.

Ce n'est pas à un Français de décrire les fêtes de cette rencontre pourtant je tiens à dire que j'espère que le [illegible] organisées [illegible] lui a bien [illegible] Ville même, il se trouve que le Président du Conseil Municipal, le Docteur Brousse, est un médecin des plus estimés. Il avait tenu à ce que les médecins Britanniques ne l'oubliassent pas.

Je voudrais à propos de cette visite rappeler à nos confrères Britanniques, à ceux qui sont venus nous visiter, comme pour ceux qui n'ont point parcouru les hôpitaux Français, quelles sont pratiquement les conditions de nos établissements scientifiques et de nos établissements de bienfaisance. Au cours de ces journées j'ai été souvent interrogé sur plusieurs points, sur certaines conditions de notre éducation médicale et sur certaines conditions de notre assistance publique qui ont paru surprendre nos confrères. Certaines conditions leur ont paru peu comprehensibles. Certaines dispositions [illegible] montrer ici [illegible] tions et qui [illegible]

Un fait domine toutes nos institutions. En Grande Bretagne l'effort individuel est toujours libre et encouragé. En France des institutions de commune et d'état le remplacent souvent et l'empêchent de se développer. En Grande Bretagne nombreux sont les groupes dont on a respecté l'autonomie. En France centralisation à outrance. Les deux systèmes ont des avantages et des inconvénients et cadrent avec les mœurs très différentes des deux pays. Mais s'il est juste pour ceux qui souffrent d'un système de s'en plaindre il est juste aussi d'en reconnaitre les avantages.

L'enseignement médical est avant toutes choses tout particulièrement centralisé puisque Paris, à lui seul, produit beaucoup plus de médecins que les six autres Facultés Françaises de province ensemble. La faculté de Médecine de Paris représente théoriquement une agglomération de six mille étudiants en médecine en cours d'étude. On conçoit qu'une pareille agglomération doive échapper à toute surveillance disciplinaire et l'on peut dire qu'à Paris l'élève de l'enseignement supérieur est en état de liberté absolue tandis que l'élève de l'enseignement secondaire (lycées et écoles d'enseignement) était dans un état de surveillance et même de réclusion, ce qui est déjà bien différent de ce que l'on voit dans le Royaume Uni. Sauf certaines conditions d'examen et d'actes de présence pour certains travaux (anatomie et physiologie) il est absolument libre de travailler beaucoup ou de ne rien faire du tout. Les hôpitaux Parisiens ne sont pas comme les grands hôpitaux de Londres, des écoles et des centres d'enseignement. Cependant ils jouent dans cet enseignement un rôle considérable. La Faculté de Médecine leur emprunte bien [illegible] faire des services de clinique [illegible] t là qu'une très faible [illegible] Celui-ci est surtout [illegible] les hôpitaux Parisiens. Aux heures de visite, tout étudiant comme tout médecin a le droit, la liberté absolue de pénétrer partout. Il peut suivre toute visite. Il peut être appelé par le chef de service à participer à l'enseignement donné dans le service.

Le concours a fait de tout chef de service un professeur. Habitué par la préparation du concours, à la parole à la leçon impromptue, malgré l'absence de toute mission officielle, par coutume et par tradition, le chef de service est partout un maitre qui peut se faire entendre. Beaucoup de ces services, sans qualification officielle, ont été des centres d'études considérables et sont connus dans le monde entier.

Les études cliniques des élèves ont surtout pour fondement l'organisation du concours de l'internat. Les élèves dans les hôpitaux, les aides directs des chefs de services sont les externes et les internes. Ils ne peuvent les choisir que parmi eux. Deux degrès de concours les mènent au titre et à la fonction. Ils représentent une minorité, car les élèves en cours d'études à la Faculté de Médecine de Paris étant estimés au nombre de six mille, il y a seulement 750 externes et 240 internes. Les externes sont nommés pour trois ans; les internes pour quatre ans. Cela ne fait qu'un millier d'élèves, c'est à dire un sixième de ceux qui seront qualifiés pour l'exercice de la médecine. Mais on remarquera surtout le petit nombre des internes: 60 à 70 au plus chaque année deviennent internes. Le travail de préparation de cet internat représente un effort considérable, une éducation préalable extrêmement complète. Il en résulte que nos aides dans les hôpitaux ont déjà par eux même des titres personnels et une véritable valeur scientifique. Mais il en résulte aussi pour eux une durée considérable des études proprement dites.

Un bon élève qui passera par l'externat et l'internat n'arrive guère à l'externat qu'en troisième, à l'internat en quatrième ou en cinquième année d'études médicales proprement dites et souvent plus tard. L'internat durant quatre an ses études proprement dites sont de huit à dix années au moins. En compensation, la pratique hospitalière en fait un sujet très expert en clinique médicale, chirurgicale ou obstétricale. Il a quatre ans d'expérience hospitalière incomparable. Ce système a même pour l'éducation générale de très grands avantages car les internes agissent habituellement comme maitres vis à vis des autres élèves. L'enseignement mutuel est très en honneur dans les hôpitaux de Paris.

Cet enseignement est très peu coûteux pour les élèves car tous ceux qui conduisent ces études cliniques ne reçoivent aucune rémuneration. Un nombre seulement de médecins ou chirurgiens reçoivent de la Faculté de Médecine une petite somme pour prendre soin des élèves stagiaires, c'est à dire de tous les élèves non externes ni internes qui sont obligés de passer deux ans dans les services des hôpitaux et de justifier que pendant ce temps ils ont étudié la clinique. Le service des externes et internes compte pour ce stage.

Tous les chefs de service des hôpitaux ont été nommés à la suite de concours, c'est à dire qu'il leur a fallu justifier en public de leurs aptitudes pour la clinique, de leur éducation générale et de leur aptitude à parler et à écrire scientifiquement. Le concours a ses défauts et ses qualités. Il a comme qualité incontestable de donner un ensemble de médecins nécessairement instruits. Une fois qu'ils sont entrés par le concours des hôpitaux ils occupent les places successivement, par une hierarchie fondée sur l'ancienneté de nomination. On remarquera que presque tous les chefs de service ont commencé par être internes.

L'organisation des hôpitaux est sans analogie avec celle des hôpitaux Britanniques issus de l'initiative privée. L'administration de l'Assistance Publique, à coté de laquelle les établissements de bienfaisance privée ne représentent qu'une infime minorité, est chargée de toutes les formes de secours au pauvre, à l'indigent. L'indigent qui habite Paris a un véritable droit à ce secours. Les ressources de cette administration viennent de ses propriétés personnelles issues de dons généreux, de certains droits qui lui sont attribués (droit des pauvres ou contributions de tous les spectacles) et d'une subvention de la ville de Paris. Son budget annuel depassé 45,000,000 de francs. Le but qu'elle poursuit c'est de répondre au droit qu'à Paris tout indigent a d'être hospitalisé ou secouru. De fait ce programme est réalisé. On peut constater qu'aucun des malades pauvres voulant entrer à l'hôpital n'est refusé. Cette facilité d'accès amène même quelques conditions fâcheuses pour le service.

Malgré d'énormes efforts financiers les hôpitaux de Paris sont loin de pouvoir fournir une place normale aux pauvres malades. Le population pauvre s'est augmentée bien plus que la population riche. Aussi pour ne refuser aucun malade les services s'encombrent de lits supplémentaires. Cela donne à nos salles un aspect particulier. Déjà les lits normaux des malades y sont plus rapprochés que dans la plupart des hôpitaux Anglais. Mais lorsque de brancards ont été mis le lits sont extraordinairement serrés. Dans mon service de l'Hôtel-Dieu, ou j'ai 56 lits reguliers souvent, en hiver surtout il y a plus de cent malades. Il arrive qu'outre les brancards il y ait des matelas à terre lorsque les lits supplémentaires ont manqué. C'est là sans doute quelque chose de très mauvais pour le service. Les accumulations de la population en certaines régions font que certains hôpitaux sont plus particulièrement encombrés : Hôtel-Dieu, Lariboisière, St. Louis, Beaujon. Dans l'hôpital dont les habitants sont ainsi doublés le budget reste le même et le personnel est aussi le même. Il en résulte une surcharge difficile pour les finances et un surmenage effrayant du personnel de service.

L'encombrement dans les services de chirurgie a des conséquences particulièrement graves. On doit le redouter d'une façon spéciale parcequ'il crée des chances d'infection. On a cherché à remedier aux inconvénients de la promiscuité. Quelques chirurgiens ont voulu subdiviser les services en services de suppurants et services de non suppurants. Mais d'une part cette séparation n'est pas facile à réaliser. Elle exige une appropriation spéciale des locaux qui ne se trouve que dans les hôpitaux neufs. Enfin, elle n'est utile que là où la méthode de Lister n'est pas rigoureusement employée. Il suffirait sans doute d'écarter certains sujets des services généraux. Malheureusement ces sujets y sont toujours conservés, les anthrax, les grands phlegmons septiques, les infections puerpérales. Ce n'est que depuis peu que les érysipèles ont été enlevés des services de chirurgie d'une façon systématique. La création de nouveaux hôpitaux est le véritable remède. On le poursuit.

Nos confrères ont pu voir qu'à Paris comme à Londres les maladies contagieuses ont été isolées systématiquement. Il y a des services spéciaux pour la variole, la scarlatine, la diphtérie, la rougéole. Toutefois il y a chez nous deux infériorités marquées. Les meilleurs hôpitaux d'isolement ne sont pas encore [illegible] it d'abord dans des locaux [illegible] is surtout nos mœurs n'ont p [illegible] de la loi sur les maladies contagieuses, le public et souvent les médecins eux-mêmes n'ont pas obéi à la loi; cependant depuis quelques années de grands progrès ont été faits. Pour la variole en particulier l'isolement d'une part, et les mesures de vaccination générale l'ont fait disparaitre dans une large mesure. L'hôpital des contagieux de l'Institut Pasteur représente une forme très particulière de l'isolement des malades séparés en chambres individuelles. Il s'agit là d'une expérience faite à très grands frais.

Les hôpitaux à Paris sont d'aspect très irreguliers. Les uns sont vieux et mal construits pour l'usage. Les autres sont plutôt trop luxueux. C'est le cas des derniers construits comme l'Hôpital Boucicaut. C'est un fait que l'on observe un peu partout. Il est pardonnable pour une administration autonome comme celle de l'Institut Pasteur dont la mission est de faire le mieux possible. Elle n'est pas pardonnable à une administration qui est chargée de ménager le bien des pauvres. Elle n'est pas pardonnable pour les agents de cette administration, les médecins et les chirurgiens qui devraient en toutes circonstances rechercher les moyens les plus économiques en même temps qu'ils sont les plus sûrs pour la guérison des malades.

Un fait a paru frapper nos visiteurs, le temps considérable consacré par chacun de nous à notre service d'hôpital. Ce service est fait chaque matin par le chef de service lui même et ordinairement entre neuf heures et midi toute la matinée est consacrée par lui à son service hospitalier. En chirurgie, dans la journée et la nuit seulement les cas d'urgence sont opérés par les chirurgiens recemment nommés dont la fonction est d'abord de remplacer les chirurgiens titulaires. Ils sont de garde tour à tour et appelés au telephone par les internes constamment en service à l'hôpital. En compensation de ce travail local très intense un médecin ni un chirurgien n'est jamais comme à Londres attaché à plusieurs établissements hospitaliers. Pour ses services le médecin ou le chirurgien ne reçoit pas de paiement à proprement parler. Il lui est alloué une *indemnité* pécuniaire insignifiante. A l'Hôtel-Dieu je touche chaque mois cent francs excepté en cas de congé ou ces cent francs sont remis a mon remplaçant.

A Paris les études scientifiques sont complètement séparées des études médicales proprement dites. La Sorbonne, la Faculté des Sciences, le Collège de France, le Jardin des Plantes forment des services éloignés et distincts. Malgré l'importance du Musée du Jardin des Plantes nous n'avons point de Musée comme le Musée Hunter où soient réunies toutes les pièces concernant toutes les sciences naturelles, y compris la médecine. Sauf l'Hôpital St. Louis qui a un musée composé surtout de pièces moulées consacrées à la description des maladies de la peau et le musée de l'Hôpital Necker consacré aux maladies des voies urinaires il n'y a dans les hôpitaux aucun musée d'anatomie pathologique. C'est un grand malheur pour les hôpitaux où les autopsies sont faites plus souvent qu'en Angleterre et où on aurait amassé des collections importantes en conservant une petite partie des pièces qui ont été étudiées.

Nos confrères ont aussi remarqué la grande différence qui existe entre leurs hôpitaux et les nôtres pour le personnel des aides. Nos aides médecins sont instruits et laborieux et relativement nombreuse mais ne sont pas choisis par nous. Ils coûtent fort peu à l'administration. Les externes ne sont pas payés et les internes le sont très misérablement. Le personnel d'aides non medical est bien loin de celui que nous avons vu dans les hôpitaux de la Grande Bretagne. Il est payé mais d'une façon tout à fait insuffisante. Il se compose d'un très petit nombre de surveillantes et pour deux hôpitaux encore, de religieuses qui dirigent le personnel d'infirmiers ou d'infirmières dont malheureusement la fonction est habituellement mixte et qui s'occupent alternativement des soins de propreté de la salle et des soins medicaux des malades. Depuis quelques années l'Assistance Publique a pris à cœur la modification de cette situation. De très grands efforts sont faits pour avoir un corps d'infirmiers

tout à fait séparé de celui des saniteurs. Mais la question de dépense qui applique à tous les établissements hospitaliers met en présence de frais enormes fait que la solution de cette question sera très lente à obtenir. Nous devons nous résigner pour longtemps à une grande infériorité sur ce point.

Pour prendre une idée des obligations de l'Assistance Publique, il ne faut pas oublier qu'en dehors d'hôpitaux, elle a la charge des bureaux de bienfaisance, c'est à dire des secours directs en ville, des accouchements des pauvres, des enfants abandonnés, des vieillards infirmes, des établissements pour les maladies contagieuses, et qu'elle possede en province nombre d'établissements de convalescence ou de traitement et de vieillards. Sans doute ces charges enormes font que chaque malade ou chaque pauvre secouru n'est pas secouru avec autant de luxe ou autant de confort qu'on le fait à l'étranger. Mais il est probable que le secours atteint un plus grand nombre d'individus. Dans la ville de Paris l'indigent est fort de son droit et vient demander les secours ou l'entrée à l'hôpital non comme une faveur, un fait de charité, mais comme un droit. L'administration de l'Assistance Publique a été l'objet de bien des critiques. Cependant, la diffusion des secours est bien réelle non seulement pour la maladie, mais pour les accouchements qui ont un service d'hôpital et de ville réellement bien organisé.

Il existe à Paris un bon nombre d'établissements privés quoique la loi recente chassant les congrégations ait fait disparaitre les plus importants d'entre eux. L'Institut Pasteur est une rare exception parmi les établissements parcequ'il est absolument œuvre privée. On a vu l'admirable installation de ses services scientifiques et l'établissement de son service hospitalier qui est en voie d'achèvement. L'Assistance Publique n'est là pour rien. Le luxe hospitalier est considèrable mais combiné avec le développement parfait des services scientifiques.

Nous espérons que malgré la brièveté de leur séjour nos confrères Britanniques auront pu prendre une idée nette de nos institutions. Ils auront pu voir surtout combien est facile l'accès de l'hôpital aussi bien que celui de tout centre d'enseignement. Sans doute la différence des langues crée un obstacle sérieux, le nombre des Français parlant couramment l'Anglais n'étant pas très considérable. Cependant ce n'est pas là un obstacle insurmontable. Aussi, nous espérons bien que cette visite trop rapide leur aura donné de sérieuses idées de retour. L'entente parfaite des deux nations devrait s'accompagner d'une entente scientifique très profitable aux deux nations. Le groupement des maitres de la science médicale des deux nations projeté par M. Sillonville qui a eu l'idée première de ce rapprochement parait susceptible d'un très grand développement. Les mœurs et les habitudes scientifiques sont si différentes en France et en Angleterre que ce rapprochement sera riche d'enseigenements pour les deux pays. Les deux visites réciproques nous ont montré que malgré ces divergences, la cordialité de l'acceuil, l'analogie de la liberté de l'esprit philosophique, le désir de la marche vers le progrès pacifique, ont tout préparé pour cette union scientifique dont le début remonte aux siècles passés.

Nos confrères ont pu voir que l'activité scientifique est considérable en particulier dans nos hôpitaux. De tout temps les études cliniques ont été en honneur en France. Elles sont poursuivies chez nous avec une grande liberté qui nous parait très profitable pour tous ceux qui veulent les suivre et en apprécier le progrès.

A Post-Graduate Lecture

ON

LARYNGEAL PARALYSES AND THEIR DIAGNOSTIC VALUE.

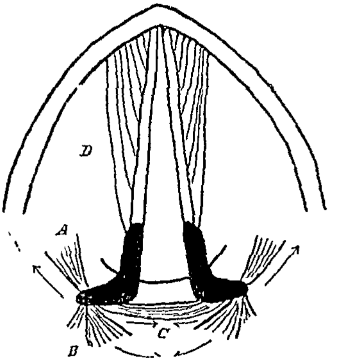
Delivered at Mount Vernon Hospital for Diseases of the Chest on Feb. 9th, 1905,

BY HAROLD BARWELL, M.B. LOND., F.R.C.S. ENG.,

LARYNGOLOGIST TO THE HOSPITAL; ASSISTANT SURGEON TO THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL; CLINICAL ASSISTANT TO THE THROAT DEPARTMENT, ST. GEORGE'S HOSPITAL; CONSULTING SURGEON FOR THROAT AND EAR DISEASES TO THE CRIPPLES' HOME FOR GIRLS.

GENTLEMEN,—The larynx is frequently affected by lesions of organs at a distance through disturbance of its innervation and the appearances thus produced make the laryngoscope of great importance to the physician as an aid to diagnosis; its use may be compared with that of the ophthalmoscope in cases of cerebral tumour. More especially is this the case in that many of these laryngeal palsies give rise to no symptoms whatever, and cannot be diagnosed or even suspected without laryngoscopic examination. I wish to lay stress upon this because there is a general impression that if there is no hoarseness, if the patient can speak and even sing normally, there can be no paralysis. This, however, is not the case, for in the common form—abductor paralysis—there need be no disturbance of vocalisation. As I propose to discuss only motor lesions to-day I will dismiss the superior laryngeal nerves very shortly; these are the sensory nerves of the larynx but supply one pair of muscles, the crico-thyroids. Owing to the short course of these nerves isolated paralysis of the crico-thyroid muscle is very rare but it occurs occasionally from section of the nerve—especially in suicidal wounds, and from pressure on it by tumours and enlarged glands. Lesions of the vagus above the origin of this branch will also paralyse the crico-thyroid, but the palsy, the signs of which are not well-marked, will be obscured by that of the other muscles of the cord. The action of the muscle is to render the cord tense, and when it is paralysed the affected cord remains slack on phonation and flaps up and down with respiration; the voice is not lost but is weak and easily tired. The remaining muscles are supplied by the recurrent laryngeal nerve. The crico arytenoideus posticus is inserted into the muscular

FIG. 1.



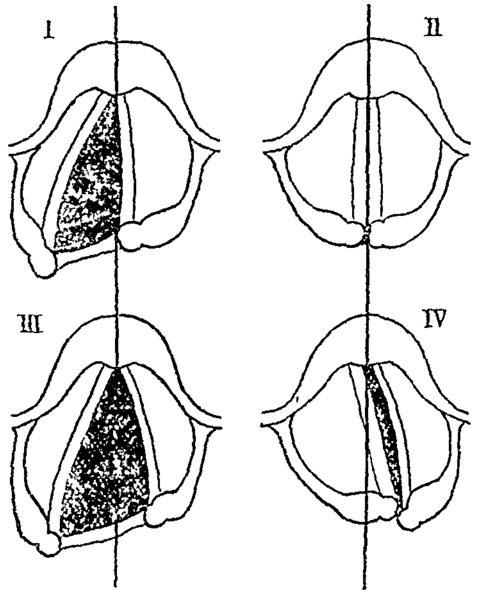
Schema illustrating the action of the intrinsic laryngeal muscles (after Watson Williams). A. Crico arytenoideus lateralis B. Crico arytenoideus posticus. C. Arytenoideus. D. Thyro-arytenoideus.

process of the arytenoid and acts by rotating the cartilage about a vertical axis and so moving the vocal process outwards and abducting the cord; the lower fibres cause a gliding movement, drawing the cartilage outwards and backwards; further, by fixing the cartilage from behind it allows the crico-thyroid to make the cord tense. The crico-arytenoideus lateralis rotates the arytenoid in the opposite direction, adducting the vocal process and cord; it does not adduct the cartilage as a whole. This action, which closes the cartilaginous part of the glottis, is performed by the arytenoideus. The thyro-arytenoideus, or "internal tensor," lies along the outer side of the vocal cord which forms its tendinous margin. Acting alone it would draw the arytenoid forward and relax the cord, but when the cord is tightened by the crico-thyroid its contraction renders the edge of the cord sharp and straight.

During phonation the edges of the cords are straight, parallel, and almost in contact; on deep inspiration they are widely abducted. Most people show hardly any movement of the cords during quiet breathing; the "position of rest" is fairly constant and is maintained by a tonic action of the abductors, for in the "cadaveric position," assumed after death or in complete paralysis, the cords are distinctly nearer the middle line. In any gradually progressive lesion of the nerve path the muscles become affected in a certain definite order, the enunciation of which is known as Semon's law. The abductor (*crico-arytenoideus posticus*) is the first affected and may remain for years the only muscle paralysed; then the internal tensor fails, and finally the lateralis muscle becomes powerless. The arytenoideus is not paralysed in unilateral cases, for its nerve-supply comes from both recurrent laryngeal nerves.

There has been in the past a very lively discussion as to the cause of this peculiar sequence of events. Krause believes that the median position, which the cord at first assumes, is due not to paralysis but to spasm, and that the more powerful adductors overcome the weak abductor muscle; but it has been shown, especially by Semon, that the abductors are less resistant and lose their irritability sooner than the adductors; post mortem the abductor muscle is found to be early and extensively atrophied in these cases, and it is improbable that a spasmodic contraction could hold the cord in the median position for years. There is little doubt that the lesion is a paralytic one and that the most vulnerable muscle succumbs first; the abductors are analogous to the extensors of the limbs, which are also more readily damaged than the flexors.

FIG. 2.



I., Left abductor paralysis; inspiration. II., Left abductor paralysis; phonation. III., Left recurrent paralysis; inspiration. IV., Left recurrent paralysis; phonation.

When abductor paralysis has occurred the affected cord lies in the middle line; during phonation the sound cord adducts to meet it and the larynx appears normal, but on inspiration the affected arytenoid remains in the same position, while the sound one is drawn outwards and backwards behind the level of its fellow, making the paralysed cord appear the shorter; in this position the sound cord also lies at a slightly lower level, because the crico-arytenoid joint is placed obliquely with its outer end lower than the inner. There is no alteration in the voice; as the maximum available aperture is reduced by half there will be some dyspnœa on active exertion, but in adults there is no obstruction to quiet breathing; owing to the much smaller size of the glottis in children unilateral abductor paralysis does cause dyspnœa which occasionally may be so severe as to necessitate tracheotomy.

In the cases of bilateral abductor paralysis both cords lie together near the middle line; when paralysis is complete they do not abduct at all on inspiration but, on the contrary, are drawn closer together; this is due to the shape of the cords, the sharp edges of which look upwards and inwards and act under the downward rush of air somewhat like the cusps of the aortic valves. In consequence, dyspnœa is a marked symptom, it is inspiratory and accompanied by stridor; severe paroxysmal exacerbations are prone to occur not only on the slightest exertion but also during sleep, and these may at any time prove fatal; for this reason it is advisable in all such cases to perform tracheotomy as a precautionary measure; a plug may be worn in the tube but it can be rapidly removed when dyspnœa becomes urgent. Phonation is quite good, but the difficulty in taking a full inspiration gives to the speech a peculiar breathless character.

When the thyro-arytenoid muscle fails the edge of the cord is no longer straight but forms a concave line, but the cartilaginous glottis is still well closed; the cord appears more rounded and narrower, first, because it retracts behind the ventricular band, and later from atrophy of the muscle. The voice now becomes gradually hoarser. Finally, when total recurrent paralysis has occurred the cord assumes a position between the middle line and the normal position of rest; this is called the "cadaveric position." During inspiration the sound arytenoid lies abducted and at a posterior level; on phonation it is drawn across the middle line by the unparalysed interarytenoideus and pushes the paralysed cartilage obliquely aside and usually backwards, probably because the structures of the affected cord are rendered slack by atrophy; the sound cord lies at a slightly higher level than the paralysed one on phonation. As the cords are still able to meet, the voice is not lost but it is hoarse and easily tired; it sometimes has a peculiar "rattling" quality due to the coarse vibrations of the slack cord. In bilateral recurrent paralysis, the severe dyspnœa present in the stage of double abductor paralysis passes off and the voice is lost. Both cords lie in the cadaveric position; sometimes even now a slight inward movement of the arytenoids may be seen on attempted phonation, owing to the action of a partially active arytenoideus muscle; it has been conjectured this muscle may at times receive part of its supply from the superior laryngeal nerve.

The diagnosis of cord paralysis can only be made by inspection but with the laryngoscope it is usually easy; even when the patient is very intolerant and only a fleeting glimpse of the posterior part of the larynx can at first be obtained, the view of one arytenoid lying asymmetrically behind the other is strongly suspicious and should put the observer on the track. Sometimes in nervous patients the cords are imperfectly separated, or even adducted, during inspiration and may thus assume the aspect of double abductor paralysis; if the patient is directed to phonate as long as he can, the cords will abduct naturally during the involuntary inspiration which follows. Fixation of the arytenoid cartilage may occur, sometimes from disease of the crico-arytenoid joint, but more often from adhesions around it; the cause may be syphilis, tubercle, or simple perichondritis occurring after typhoid fever, diphtheria, or other infective fever. The cartilage is usually fixed near the cadaveric position, so that the diagnosis has to be made not so much from abductor palsy as from complete recurrent paralysis. The distinction is seldom difficult, for fixation is nearly always accompanied by scars, swelling, or deformity; when this is not the case the diagnosis can only be made by observing that the immobile cartilage is really absolutely motionless and on phonation is not pushed aside by the sound arytenoid, as it is in cases of unilateral recurrent paralysis. When a cord has been long paralysed some fixation of the joint usually results and the voice becomes stronger in consequence; in such cases of old standing a certain diagnosis between paralysis and fixation may not be possible.

We must now consider the causes of these paralyses, for on our knowledge of them depends the diagnostic value of these lesions The larynx is an organ which has two functions, more or less antagonistic, that of phonation and that of respiration, the adductor muscles subserve the former function and the abductors the latter Of the two, phonation is the more recently acquired and, being directly controlled by the will, has a well-marked cortical centre, situated bilaterally in the lower part of the ascending frontal convolution; stimulation of either "phonatory" centre causes adduction of both vocal cords On the other hand, the respiratory function is older, more vital, and less under conscious control, it can be maintained by the medullary centres after ablation of both cerebral hemispheres in dogs Although a cortical centre for abduction has been found near the phonatory centre it is less well defined In accordance with this functional disturbances always produce paralysis of the phonatory mechanism, while organic lesions paralyse the abductor muscles From these considerations it appears that no unilateral lesion above the bulbar nuclei can paralyse the cords, for they are controlled by both cerebral hemispheres, and that if both tracts from the cortex are destroyed the resulting paralysis must affect both cords and be adductor in type, as in a case reported by Eisenlohr And this is in accordance with clinical experience, in cases of hemiplegia, even with aphasia, the larynx is not paralysed any more than are the muscles of respiration Four cases are recorded (two by Déjerine and two by Garel and Dor) where unilateral cerebral lesions appeared to cause unilateral paralysis of the opposite cord, but as in all four the cord assumed the cadaveric position it may well be argued with *Horsley and Semon that the lower neuron must have been* affected, for the abductor function is controlled by the bulbar nuclei

From the bulbar nucleus the nerve fibres pass in the roots of the bulbar accessory to the vagus and thence to the recurrent laryngeal, the lesion causing paralysis may, therefore, be situated (1) in the medulla, (2) at the base of the brain, (3) in the vagus, or (4) in the recurrent laryngeal nerve. The cause is often hard to find, according to Lermoyez[1] it remains undiscovered in more than a third of cases, recurrent paralysis occurs twice more often in men and twice more often on the left side

In cases of paralysis from bulbar disease and from lesions at the base of the brain neighbouring nuclei are prone to be affected as well, the soft palate, uvula, and pharynx are supplied from the bulbar accessory centre, paralysis of *one cord and of the same side of the palate* is an important symptom complex and points to nuclear disease, a few rare cases have been recorded of paralysis of cord, palate, sterno mastoid, and trapezius from involvement of the bulbar and spinal accessory roots Persistent frequency of the pulse, due to disease of the cardio inhibitory centre, is an important sign of bulbar disease Paralyses of bulbar origin are frequently, but by no means always, bilateral Tabes dorsalis is the commonest cause of cord paralysis of bulbar origin and is so common that it should always be thought of in cases of palsy of uncertain causation, it may affect one or both cords Though usually associated with other better known symptoms, it may be for years the only discoverable lesion, Lermoyez states that 34 out of 100 tabetics had laryngeal troubles Other laryngeal neuroses are found in tabes—anæsthesia, paræsthesia, and the so called "laryngeal crises", these begin with a series of coughs resembling whooping cough, the glottis being closed by a spasm which is occasionally so severe and prolonged as to prove fatal In general paralysis abductor palsy is not uncommon, Permewan observed it seven times in 34 cases Syphilitic nuclear disease, gummata at the base of the brain, and syphilitic pachymeningitis are fruitful causes of laryngeal palsy, the ocular muscles, especially the external rectus, are often affected as well In bulbar paralysis laryngeal palsy is the rule and is nearly always bilateral, but it rarely appears until late in the disease, when the tongue is atrophied and the palate and pharynx are paretic Syringomyelia and amyotrophic lateral sclerosis are rarer causes, disseminated sclerosis seldom produces paralysis, but the intention tremors may be well seen in the larynx

Of peripheral causes, neuritis is probably a more frequent factor than was until lately supposed. Several forms may be distinguished, toxic, due by far the most often to lead, rarely to alcohol and arsenic, and infective, due chiefly to diphtheria, less often to typhoid, influenza, and other fevers, in such cases other typical lesions of neuritis will usually coexist. Some cases of paralysis occurring in the course of tubercle or syphilis may be explained by a neuritis In addition there are cases of so called primary neuritis similar to cases of Bell's facial palsy where the paralysis is transient and the only cause appears to be "cold" Here one may mention those cases where the posticus muscle seems to have been directly injured by the passage of a large or hard body down the œsophagus

In lesions of the vagus above the origin of the superior laryngeal nerve the sensory fibres from the larynx are involved, producing at times anæsthesia or reflex bilateral spasm of the glottis Peripheral lesions, however, more often affect the vagus below this level or the recurrent laryngeal nerve, they are rarely bilateral Traumatism is a rare cause, perhaps it most often results from a surgical operation, especially excision of the thyroid gland or œsophagotomy, the cord, of course, assumes at once the cadaveric position Paralysis is usually due to compression of the nerve and the most frequent causes of this compression are, in order, (1) aneurysm, (2) enlarged glands, usually tuberculous, sometimes syphilitic or malignant, and (3) cancer of the œsophagus Rarer causes are mediastinal growths, pulmonary tubercle, goitre, cancer of the lung, pleurisy, and massive pericardial effusion

Of all causes of laryngeal palsy aneurysm is the most frequent, though tabes comes not far behind The left cord is the most often affected owing to the course of the left recurrent nerve but an aneurysm of the innominate may compress the right cord and bilateral paralysis has resulted from a very large aortic aneurysm and from the simultaneous presence of two aneurysms. In addition to paralysis the pressure of an aneurysm may cause glottic spasm, not by *compressing the recurrent nerve which contains no afferent* fibres except some of muscular sense but by irritation of the vagus or trachea, the same irritation causes the cough of aneurysm which has as a rule a peculiar "brassy" quality, though if there is complete paralysis of a cord it loses this character and becomes "wheezy" like the cough of a cow Finally, in cases of aneurysm dyspnœa may result from pressure on the trachea or a main bronchus, if the trachea is compressed the narrowing may be visible with the laryngoscope or a pulsating area may be seen, according to Moritz Schmidt[2] a slight pulsation of the tracheal wall where it is crossed by the aorta may sometimes be seen in healthy persons In a doubtful case of thoracic tumour I believe that paralysis of the left cord is somewhat in favour of aneurysm rather than of a mediastinal new growth This paralysis of the left vocal cord is often the earliest, and for *some* time the only, sign of thoracic aneurysm, a small aneurysm in the concavity of the aortic arch may early cause laryngeal palsy but for a long time elude all attempts at diagnosis For this reason the prognosis should always be guarded in cases of cord paralysis, on the other hand, though few cases recover their mobility, unilateral palsy is not dangerous in itself and may be due to some harmless cause, such as an enlarged bronchial gland, so that the outlook is not necessarily grave

Tuberculosis is a fairly frequent cause of recurrent paralysis, either by pressure of bronchial or tracheal glands, when the left cord is generally attacked, or by involvement of the nerve in a tuberculous infiltration at the apex of the lung, the right recurrent nerve lies close to the pleura and is the most often affected in this way—so much so that unilateral paralysis of the right cord should always suggest the possibility of phthisis In addition the laryngeal muscles may be damaged by infiltration or degeneration in tuberculous laryngitis or by functional failure from general weakness Of peripheral causes of bilateral paralysis cancer of the œsophagus and goitre are the most frequent The association of laryngeal palsy with a thyroid tumour, though suspicious, is no conclusive proof of malignancy An innocent goitre may affect the recurrent nerve, especially if growing rapidly or becoming inflamed or if hæmorrhage occur into a cyst Compression of the trachea by a goitre can be well seen with the laryngoscope In bilateral cases the side-to-side compression produces a characteristic "scabbard-shaped" contraction.

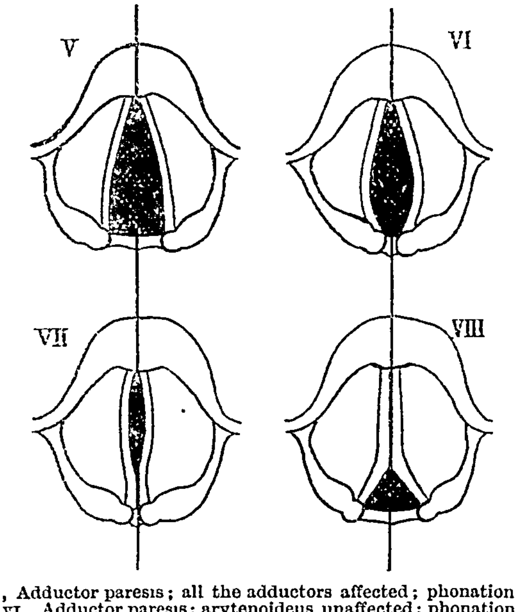
[1] Semaine Médicale, 1897, p 167

[2] Krankheiten der Oberen Luftwege, 1903

A totally different class of laryngeal palsies is that which affects the phonatory function—*adductor paralysis*. This is nearly always bilateral and is not due to organic disease of the nerve path but either to a neurosis—the so-called "functional aphonia"—or to local disease, such as laryngitis, directly interfering with the action of the muscles. Functional aphonia is a common manifestation of hysteria but it should be clearly borne in mind that many cases, probably even the majority, are not purely hysterical. Anything which makes the effort of phonation greater than usual—constitutional debility, thickening of the cords, or laryngeal catarrh—predisposes strongly to this affection, which is characteristic rather of debility than of hysteria. It occurs in men as well as in women, though much less frequently, and I see a large number of such cases among consumptives at the Mount Vernon Hospital. In purely hysterical cases the cough is usually not aphonic; the onset is sudden, as also is the recovery, for many cases regain the use of the voice, as it were miraculously, on the application of the faradic current or a strong astringent.

Paralysis is very seldom complete, usually amounting only to an imperfect apposition of the cords; unilateral adductor paralysis is extremely rare; it is due to local interference with the muscles and in a few cases to toxic causes. The three sets of adductors may be all affected, or the arytenoideus may escape, or the thyro-arytenoidei may be affected alone. The arytenoideus may, though rarely, be paralysed alone from hysteria or catarrh; this gives rise to a very peculiar appearance, a triangular chink being left at the posterior part of the glottis. Adductor paralysis may be mistaken for complete bilateral recurrent paralysis, as the cords do not come to the middle line on attempted phonation; attention must be directed to the action on deep inspiration, for in recurrent paralysis the cords will not move, but in incomplete adductor paralysis they will now move further outwards; in complete adductor paralysis there is no difficulty, for the cords are extremely abducted well away from the cadaveric position of recurrent paralysis. These adductor paralyses thus form a marked contrast to the group of abductor palsies; they produce a prominent symptom, aphonia, which attracts early attention, they are not due to serious organic disease and they are not in themselves dangerous to life.

FIG. 3.



V., Adductor paresis; all the adductors affected; phonation. VI., Adductor paresis; arytenoideus unaffected; phonation. VII., Paralysis of the thyro-arytenoidei, phonation. VIII., Paralysis of the arytenoideus; phonation.

In conclusion, I would again remark that in a knowledge of the appearance and of the causes of laryngeal paralyses we have an important aid to diagnosis in many obscure cases, an aid which the practitioner can by no means afford to neglect.

THE CONDITIONS AFFECTING THE DEVELOPMENT OF FLAGELLATED ORGANISMS FROM LEISHMAN BODIES AND THEIR BEARING ON THE PROBABLE MODE OF INFECTION.

BY LEONARD ROGERS, M.D. LOND., M.R.C.P. LOND.,
CAPTAIN, I.M.S.; ACTING PROFESSOR OF PATHOLOGY, MEDICAL COLLEGE, CALCUTTA.

IN THE LANCET of July 23rd, 1904, p. 215, I first described the development of flagellated organisms from Leishman bodies, and in the November number of the *Quarterly Journal of Microscopical Science* I described and illustrated the changes more fully, tracing the development day by day, flagellated forms being only found, as a rule, after three or four days. In one case, however, fully developed forms were found in 24 hours and these appeared to be more like trypanosomes than those which appeared on later dates in the other cultures. This suggested that in the case of the more rapid growth the conditions must in some way have been unusually favourable and led me to carry out a very long series of experiments to determine the optimum conditions for the development in the hope that if found they would throw light on the probable mode of infection of the diseases caused by this parasite. For many months no progress other than that of a negative nature resulted, but recently an important advance has been made which appears to me to indicate strongly the direction in which the solution will be found of the difficult question of the manner in which the infection of the disease is conveyed from one person to another. I propose in the present paper briefly to record the general results of my attempts to cultivate the parasite under different conditions and then to discuss the bearing of these on the probable mode of infection of the disease.

My observations on the development of the flagellated forms have been already confirmed by my assistant, Dr. G. C. Chatterjee, Lieutenant S. R. Christophers, I.M.S., and by Major W. B. Leishman, R.A.M.C., and Captain C. J. B. Statham, R.A.M.C., and I have very little to add to the descriptions I have already published except some minor details. In the first place I should have mentioned the very marked vacuolation which is present from the first enlargement of the organisms up to the flagellated stage in varying degrees, being most marked in large and broad forms, and least in the longest, thin, and most completely developed ones. Another interesting point which I noted early in the inquiry, but the full significance of which was only gradually worked out, is a well-marked eosin-staining body of a round or oval shape, which usually appears on the second day, and is commonly situated between the macro- and micro-nucleus. When the stage of elongation is reached it travels up to what will become the anterior or flagellated end of the now pyriform double body and carries with it the micronucleus. When the flagella first appear they are seen as short processes projecting from these eosin bodies, and at this stage they cannot as a rule be traced to the position of the micronuclei. In the later stages, especially in the separate completely developed long flagellate forms, this body is absent, while in nearly complete stages I have frequently seen it either partly or completely extruded from the organism, and then the flagella can be traced close up to the micronucleus. It is possible that this extrusion may have been due to pressure in preparing the film, but I am inclined to think that it is a part of the developmental process, although I am unable to explain its significance. This eosin-staining body has been independently described by Major Lenehan, whose term "flagella body" appears to be a good one. A more marked feature of my long experience is the uncertainty of the development of fully flagellated forms being obtained in the cultures in citrated blood, although the earlier stages are nearly always seen. Success depends very largely on the number of parasites found in the spleen blood preparations used, only those in which they are numerous, which form a small proportion of the whole, as a rule giving good results. This is especially the case when the parasites are large and fat, the small shrunken ones, commonly met with in very chronic cases of the disease with very large hard spleen, seldom developing at all well. Again, if any micro-organisms are present and multiply rapidly the protozoal parasites degenerate and disappear. This applies especially to the presence of cocci, which are commonly found in the spleen and rarely even in the peripheral blood during the latter stages of the disease, and especially when cancrum oris is present, owing to an invasion of the system due to diminished phagocytic power of the blood, as I have several times demonstrated. On account of these various reasons I have only obtained fully developed flagellate forms in ten out of 60 attempts at culture in citrated bloods. Another marked feature is that in most of the successful cases the number of flagellated forms has been very small in proportion to the total number of the original and partly developed parasites present, multiplication of the smaller forms being a more marked feature than the pairing and elongation into flagellated forms, so that it is often necessary to examine several films carefully to find any of the latter. It is evident from this that the citrated blood is more suitable to the simple multiplication of the organisms than to their ultimate development into flagellated organisms.

The facts just recorded led me to believe that citrated blood was not the optimum condition for the flagellation of the parasites, so repeated endeavours were made to discover a more favourable medium in the hope that it would furnish a clue to the natural conditions under which the organism exists outside the human body. The results obtained so far may be briefly summarised under the following heads.

Citrated spleen blood added to sterile distilled water.—Several experiments have been made by this method but no development has ever been obtained, although in controls of the same spleen bloods in citrated normal salt solution development has been traced. As a rule the organisms disappear in three or four days in sterile water, but in one case small undeveloped forms were found as late as the ninth day, a very large number having been originally added. If, however, the water is not sterile and bacilli or cocci develop the protozoal parasites rapidly die out. As they are not likely to find their way into sterile water in nature it does not appear at all probable that water is the medium in which they live outside the human body, although they might survive long enough in it to be swallowed by some form of animal life.

Different strengths of salt solution.—The fact that flagellation of malarial parasites was found by Ross to be brought about by concentration of the blood in the mosquito's stomach naturally suggested the trial of different strengths of salt solution as a culture medium for Leishman bodies. 5 per cent. citrate of soda dissolved in NaCl solutions of strengths varying from 0·5 to 1·4 per cent. were used. The greatest strength appeared to be unfavourable to the development, but variations of from 0·5 to 1·1 did not seem to make any difference, possibly owing to the presence of such a large percentage of citrate of soda.

Anaerobic conditions.—Of greater interest and importance is the effect of excluding oxygen from the cultures, which was done either by placing the tubes in an atmosphere of hydrogen gas or by placing them in Buchner's tubes and absorbing the oxygen by caustic soda and pyrogallic acid. In either case the result was the same, for no development was ever found to take place under anaerobic conditions, although in controls of the same citrated blood in ordinary atmosphere good development occurred. On the other hand, the absence of oxygen did not appear to have any deleterious effect on the organisms, for they could be found in good staining condition up to the fourteenth day in one instance, although in the control development and subsequent degeneration had occurred before that time. Moreover, in another experiment under anaerobic conditions no development had taken place at the end [illegible] well marked in the control, but [illegible] tube under ordinary atmosphe[illegible] commenced and [illegible] I. another case in a[illegible] took place in three [illegible] atmospheric oxygen very rapid and complete development in two days occurred, unusually long flagellated forms being obtained. It is clear from these experiments that anaerobic conditions while hostile to the development do not destroy the vitality of the organism.

In oxygen.—If the natural habitat of the organism outside the human body is in the circulating blood of some other form of animal life, then it would appear to be probable that the bottom of a test-tube containing citrated blood and covered with half an inch or more of fluid would not contain sufficient oxygen for the full development of the organism. In order to test this the supernatant fluid has been removed after the spleen blood has settled down and the tubes placed nearly horizontally to allow as much aeration as possible but no improved development was obtained in this way. Further, a number of cultures have been made by placing the citrated blood tubes in a bell jar and passing a current of oxygen through until the emergent current lit a glowing piece of wood. The results again have been negative, no difference in the rate or degree of development having been noted in these tubes as compared with the controls. It would appear from this that the abundant supply of oxygen, such as is present in circulating blood, is not specially favourable to the development of the flagellated form of the organism.

In acidified citrated blood.—The above attempts to find the optimum conditions of development having all proved unsuccessful I next turned my attention to the conditions obtaining in the stomachs of biting insects, and especially of bugs, the latter in particular appearing to me to be specially likely carriers of the disease, for the reasons to be given presently. On adding fresh blood to the stomach contents of bugs which had fed on blood within a day or two I found that no immediate crenation or dissolution occurred, so that the amount of salts present did not appear to differ widely from that of human blood. The contents of their stomachs, however, consisted of a grumous material, staining of a reddish-brown colour with Romanosky's method, and in most of the insects examined the red corpuscles had lost their shape and been broken up. The reaction was markedly acid, and this observation led me to try neutralising and acidifying my citrated salt solutions either before or after adding the spleen blood containing the parasites to the culture tubes. On adding weak hydrochloric acid to render the citrate solution slightly acid and resterilising by heat I found the solution had again become alkaline owing to some chemical decomposition. The use of citric acid got over this difficulty. On using such an acidified medium controlled by another culture of the same blood in the ordinary alkaline citrate solution (which I found has a somewhat greater degree of alkalinity than that of the human blood) very different results were obtained. Thus in the first attempt as much development took place in the acidified solution in 12 hours as is usually found in a successful culture in the alkaline medium after two days. At the end of 24 hours, however, I was disappointed to find that the development had not continued at the same rate which was discovered to be due to the solution having again become alkaline. On acidifying once more with citric acid development proceeded well and on the third day flagellated organisms were obtained and on the following day were numerous. In a control in alkaline solution only a very slight degree of development occurred—namely, slight enlargement—but no double elongated or flagellated forms appeared. In a third tube of the same spleen blood which was just neutralised the earlier stages of development only took place, while in a fourth tube which was acidified and placed in oxygen good development with the formation of flagellated bodies took place, although they were less numerous than in the acid tube in ordinary air, no advantage having been obtained from the excess of oxygen. In a third experiment portions of the same spleen blood were placed in three tubes of citrated normal salt solution. The first was allowed to remain alkaline, as in all the former cultures, and no development at all occurred, the number of parasites originally present [illegible] s just faintly acidified [illegible] occurred in this either. The third was [illegible] adding twice as many [illegible] ormal citric acid as was required to just neutralise [illegible] tube and the tube was placed under anaerobic [illegible] No development whatever took place by the end of the third day. On now placing the tube in the air very marked development of elongated pairs, some with commencing flagella, was noted on the following day and one day later very numerous fully elongated narrow flagellated forms were seen, some in pairs and some already separated. In fact, these forms very closely resembled the exceptionally long and complete forms which developed in my first successful cultures in 24 hours and which I had been striving to obtain again for the last nine months. It now appeared to be clear that the acid medium was far more favourable for the development than the alkaline one, for in three successive cases it had given very good results while the control alkaline cultures showed little or no development under otherwise similar conditions. That the acid medium is very favourable to the development of the flagellated forms as opposed to simple division and multiplication of the small oval spleen form of the parasites is confirmed by another very marked feature of these acid cultures. It has already been mentioned that in the alkaline medium rapid multiplication of the small forms is a more marked feature than the development of flagellated organisms and that when the latter are found in small numbers very much more numerous undeveloped and partly developed forms will be present, including many of the smallest size. On the other hand, in the acid medium when the elongated pairs and flagellate forms have appeared the small oval forms are either very few in numbers or even absent altogether. This striking fact strongly indicates the acid medium to be the optimum for the flagellation of the parasite and also points to the acid-containing contents of the stomachs of some blood-sucking insect as the place in which the parasite undergoes the extra-corporeal stage of its existence. Such an acid medium is also unfavourable to the growth of bacteria, which I have shown are very inimical to the protozoal parasites under consideration. As a matter of fact, I have found the stomach contents of bugs to be, as a rule, sterile and free from bacteria, although they may be occasionally present in large numbers. Further, on two occasions I have mixed the contents of the stomach of bugs, which had recently fed, with spleen blood containing the parasites, a portion of the former having been microscopically examined to exclude the previous presence of the parasites. No development has yet been obtained in this way but it has been found that the parasites remained in good staining condition for several days under these conditions, while as the controls did not develop in alkaline citrated blood and in one case but very few parasites were present the absence of development is not surprising. The experiments at least show that the conditions are not inimical to the continued life of the parasites, but that is all that can be said at the present time.

The above facts taken as a whole strongly indicate that the stomach of some blood-sucking insect is the most likely place in which to find the natural development of the extra-corporeal stage of the parasite and that some such insect is the most likely carrier of the infection.

The nature of the parasite.—The exact nature of the flagellated organisms which I have obtained from Leishman bodies is still uncertain. On the one hand, in favour of their being stages of a trypanosoma are the facts that they so closely resemble the various forms of trypanosoma Brucei described by Rose Bradford and Plimmer, to which may be added the fact that most of the forms obtained by Dr. Thiroux in cultures of the trypanosoma Paddæ, which are figured in the Annales of the Pasteur Institute of February, 1905, resemble very closely in appearance forms which I have obtained in my cultures. On the other hand, the failure of all observers to find any trace of an undulating membrane as yet is against this view and points rather to the organism being of the nature of a hepatomonas, but I observe in the figures in S. Prowazek's paper on the Hepatomonas in the *Arbeiten aus dem Kaisrerlichen Gesundheitsamte* that he repeatedly figures a double flagellum arising from a single micronucleus, a condition which I have never seen in any of my numerous specimens. It can only be said at present that there is nothing known incompatible with the organisms being stages of a trypanosome but proof that it is so is still incomplete and it may possibly prove to be some other form of flagellate when the forms naturally developed outside its human host are discovered.

The probable mode of infection in kala-azar and cachexial fever.—In 1897 in my report on the Assam epidemic fever kala-azar I recorded a large amount of evidence to show that the mode of communication of the disease was essentially a house infection. Thus, when tracing the spread from village to village it was nearly invariably found that someone with the fever had gone to reside in a previously uninfected village and that the next cases occurred in the household in which he lived. Further, in the rare cases among Europeans some native employé in the house had suffered from the fever before the residents were attacked. Since that time I have obtained from various sources several most instructive histories bearing on this point, which it is very necessary to record in order that the danger of infection may be avoided in the future. It is not essential to give in detail all the histories of which I have notes as they are only too similar to each other. It will suffice to say that in three cases in which there was much kala-azar in the coolie lines the infected Europeans either frequently had coolie women brought to their bungalows at night or visited them in their own lines. In three more cases the Europeans each cohabited with a native woman, each of whom was actually suffering from kala-azar and in two of these cases the women were known to have eventually died from the disease. What is still more conclusive is the fact that in two of these latter cases there was no other source of infection within several miles, as the coolie lines at these places were quite free from kala-azar at the time. The importance of recognising and avoiding such a source of infection is my reason for recording these undoubted facts. One other point must be referred to in this connexion—namely, that the moving of all the healthy people out of infected lines during the cold season, when I found new cases to be at a minimum, has proved a complete preventive of the disease as long as no infected people are admitted to the healthy lines. The line first moved at my suggestion over eight years ago has remained quite free from the disease to the present day and that, too, in spite of the fact that it is situated only half a mile away from the old infected one which has now been almost depopulated by kala-azar. It will be noted that this distance is not absolutely beyond the range of mosquito flight.

The above data refer to the Assam epidemic form of the disease but I have also some facts pointing to a similar house infection applying to the endemic form of the disease in Bengal which I have named "cachexial fever." During the last year I have been able to examine all cases of this disease admitted to the European General Hospital of Calcutta and have been much struck with the frequency with which more than one member of the same family have been admitted for cachexial fever at or about the same time. Thus within this period examples of father and child, mother and child, and several instances of two children of the same family being simultaneously affected have been met with among Europeans. All these facts bear out my original contention that the disease is a communicable one and that it is usually necessary to live for a time at least in the same house with an infected person in order to contract the disease. Further it appears probable in the light of the above facts that sleeping in the same bed is especially likely to lead to contraction of the disease, for this would account for its spread among children of the poorer European and Eurasian classes as well as in the Assam cases referred to above.

When we consider the above facts in view of my experiments proving that an acid medium is best suited to the development of the flagellated forms of the parasite and remember that such an acid medium is supplied in the stomachs of many blood-sucking insects, then we are forced to the conclusion that the most likely mode of infection is through the means of some such biting insect. But as to the most likely kind of insects to carry the infection we are on more uncertain ground, for experiment alone can determine this. Nevertheless, it is worth while to discuss which are the most probable kinds in order that precautions may be taken against them without waiting for absolute proof to be obtained. The choice will obviously depend on what we believe to be the most frequent avenue of escape from the body for the parasites. Major C. Donovan, I.M.S., describes forms with a single chromatin body as occurring in the peripheral blood, but in his coloured plate published in THE LANCET,[1] and from his descriptions I have been unable to see how he distinguishes these from ring-shaped malarial parasites which they so closely resemble. No other observer appears to have been able to find any such form in the peripheral blood. I have repeatedly taken several cubic centimetres of blood from a vein during high fever, both by day and at night, in cases in which the parasites had been found in large numbers in the spleen by puncture and after separating the bulk of the red corpuscles rapidly with the centrifuge have again centrifuged the fluid part of the blood. In this way very numerous blood plates can be found in the second sediment and any Leishman bodies would be found with them, but even by this method I have failed to find any parasites in the peripheral blood so they clearly cannot exist there in any numbers *unless*, indeed, they are present

---

[1] THE LANCET, Sept. 10th, 1904, p. 744.

[illegible] Lieu- [illegible] re fre- [illegible] on the [illegible] s from [illegible] of the [illegible] of the latter are well adapted for the development of the parasites I have indicated above, and although so far I have failed to find the parasites in bugs from the beds of patients suffering from cachexial fever in Calcutta and from kala-azar in Assam (the latter having been kindly supplied me by my friend Mr. J. Dodds Price, although they could not be examined until after a four days' journey), still I am of the opinion that bugs are the most likely carriers of the disease. That they abound in the wooden beds of natives, especially in Bengal and Assam, is quite certain while they are also a pest in the poorer native and E [illegible] native hospitals. Further work [illegible] very necessary, but I venture to [illegible] the bug or flea being the usual carriers of the disease is sufficiently great to render it advisable to take steps to [illegible] his way. [illegible] bility of [illegible] any in- [illegible] bed or [illegible] common [illegible] rable in the case of children who are very susceptible to the disease and in whom it is also exceptionally fatal, children under ten years in particular but seldom recovering from it.

In conclusion, I desire to express my thanks to Lieutenant-Colonel Harris and Lieutenant-Colonel Drury, I.M.S., for their very kind permission to make use of their cases and to Captain D. McCay, I.M.S., and Captain J. W. D. Megaw, I.M.S., for much help in examining cultures and for many valuable suggestions.

Calcutta.

A CASE OF WIDESPREAD ULCERATION OF SKIN AND CONNECTIVE TISSUE.

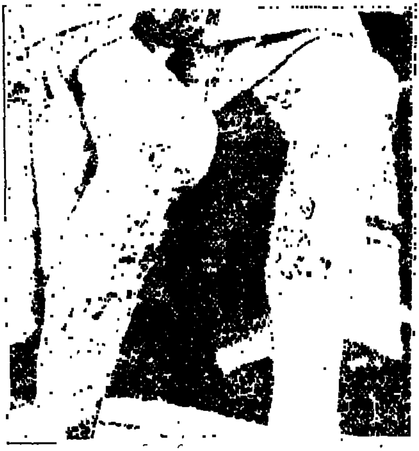
BY W. BERTRAM WATSON, M.D. LOND.,

HONORARY PHYSICIAN TO THE YORKSHIRE HOME FOR INCURABLE AND CHRONIC DISEASES, HARROGATE.

IN this paper it is proposed to give some short notice of a case of ulceration of skin and connective tissue which has recently come under my observation. The patient was a man, aged 61 years, employed in business, and came under my care in August, 1904. But for a somewhat severe attack of influenza 16 years and of pleurisy six years previously, he described himself as having been a healthy man up to the onset of the skin affection shortly to be described. He had never had syphilis and there was no family history of tubercle.

With regard to the skin affection, the patient gave the following history. In 1900 he noticed a small lump in the left buttock which slowly and painlessly increased in size and was followed in March, 1901, by a second lump which developed a little higher and nearer to the spine. Both of these ultimately burst. Shortly afterwards lumps began to form in the left groin and in August, 1901, recourse was had to surgical treatment, the lumps in the back and a number of enlarged glands from the groin being removed and the parts scraped by the late Mr. T. R. Jessop of Leeds. The result of this treatment was not satisfactory and ten weeks later the scraping was repeated. After a few months these places healed, but coincident with the improvement in these situations the disease showed itself in other localities. The course from now onwards was a progressively downward one. The skin gave way in a number of places at the back of the right chest and in the loins; early in 1902 he had considerable pain in the right shoulder and arm which was followed by inflammation of skin which broke down in numerous places and formed running sores. The same process commenced in the skin of the right leg in April, 1903, and the left leg became involved in July of the same year. From 1902 he had been compelled to lead a life of invalidism, could walk only with difficulty, and had considerable pain. His general health suffered in consequence and the body weight fell from 11 stones 7 pounds in 1900 to 9 stones in August, 1904.

The accompanying illustration will give some idea as to the character and extent of the skin lesions in August of last year. The patient could move only with considerable pain. The complexion was sallow and the blood, as evidenced by the colour of the lips and conjunctivæ, was deficient in hæmoglobin. Contrary to what one would have anticipated there was no evidence of lardaceous disease and the lungs, kidneys, and [illegible] no situation were th [illegible] It is not necessary to [illegible] tion of the skin. Many of the ulcers were deep and their bases where visible were seen to be irregular, yellow, and unhealthy. They were in varying degrees of inflammatory activity, with thin, ragged, undermined edges, and exuding thin, dirty-white pus. Some, which had entered into a quiescent state, were filled with yellowish-white grumous material. Between the skin and the bone over the shin of the right leg were several soft, semi-fluctuant tumours. On the back were scars indicating that in these situations the process of repair had been successful. With the presence of sinuses and numerous bunches of flabby, unhealthy granulations the character of the lesions, which was the same in all the localities affected, presented a complete clinical picture of tuberculous ulceration of the skin and connective tissues.



When the question of treatment came to be considered it appeared that the only possible chance of success was by means of radical surgical measures. Abscesses should be opened, fungating granulations and ulcers scraped, undermined skin cut away, and sinuses freely laid open. This would have required a series of operations under anæsthesia, which would have proved no light matter in a subject 61 years of age, exhausted by prolonged illness. This line of treatment, which was advised, was not, however, adopted as the patient was not willing to submit himself to further surgical interference. Accordingly he was kept at rest in bed and his constitution was strengthened by an abundance of good food, combined with cod-liver oil, syrup of iodide of iron in full doses, and other tonics. The ulceration of the skin was treated on ordinary antiseptic lines by means of [illegible] turn p[illegible] in a s[illegible] and b[illegible] chinosol, perchloride and biniodide of mercury being the antiseptics used. I found that Fairchild's enzymol was of special service in clearing away dead material in deep ulcers. Salicylic cream (acidi salicylici, two parts; acidi carbolici, one part; glycerine, ten parts) also proved useful. For dusting powder I made use of equal parts of iodoform and dermatol. On one occasion with the aid of local anæsthesia I incised one of the semi-fluctuant tumours over the shin, to which reference has already been made, and found it to contain curdy material. The effect of this treatment was remarkable. In a few days the ulcers cleaned and the purulent discharge diminished in quantity. The process of repair in the ulcerated surfaces was very rapid and after two months' persistent local disinfection the back, and after four months the whole of the areas involved (back, arm, legs) had completely healed. It is not necessary to give illustrations of the present condition as all they would show is extensive cicatrisation.

At the time of writing the patient is in excellent health. He is able to attend to business and his weight has increased to 11 stones. I thought that owing to contraction of cicatricial tissue walking would prove a difficulty and that it would be necessary to do something in order to free the action of the knee-joints. However, no further treatment of this kind has been required as their movement is quite free.

In conclusion, it may be mentioned that it was the opinion of the late Mr. Jessop, when he operated, that the case was tuberculous in origin.

Harrogate.

THE OPERATION OF JEJUNOSTOMY,

WITH A DESCRIPTION OF A NEW METHOD.[1]

BY A. W. MAYO ROBSON, D.SC. LEEDS, F.R.C.S. ENG.,
SENIOR VICE-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

JEJUNOSTOMY is an operation occasionally called for as a means of giving relief and prolonging life in patients suffering from advanced disease of the stomach, where on exploration it is discovered to be impracticable to perform gastrectomy, gastrostomy, or gastro-enterostomy. The indications for the operation are (1) extensive cancer of the stomach too advanced for gastrectomy and in which no healthy spot of sufficient size on the stomach wall can be found for the purpose of gastrostomy or gastro-enterostomy; and (2) general cicatricial contraction of the stomach, simple in character and due to the swallowing of caustic fluid, in which the stomach has been so far damaged that it no longer performs its functions or even allows of the proper passage onwards of food. It has also been suggested in pronounced hyperchlorhydria in preference to gastro-enterostomy in order to avoid peptic ulcer of the jejunum, but as the latter is extremely rare and practically only associated with anterior gastro-enterostomy, a method that is being replaced by the posterior operation, I do not think surgeons generally will be likely to endorse Neumann's suggestions; nor do I think that it is probable that jejunostomy will be likely to replace other methods of securing rest in the treatment of gastric ulcer or of hæmatemesis, as Cackovie has suggested, and as has been adopted on one occasion with success by Mr. Willoughby Furner.

Modes of operation.—For any operation to be a success the bowel must be so placed that it will serve the two purposes: (1) to permit the passage onward of the bile and pancreatic fluid poured into the intestine above the artificial fistula; and (2) to allow of food being introduced through the fistula without fear of regurgitation, either of the food or of the intestinal contents. In my first operation, performed in 1891, I used a method which, though successful in prolonging life, was inconvenient and cumbersome and I need not mention it further.

The operations now used are the following:—1. A modification of Witzel's method of gastrostomy in which a No. 12 rubber catheter is stitched into an opening in the jejunum and afterwards the catheter is buried in a groove in the bowel for a distance of about two inches, the line of suture being fixed to the abdominal wall (see Figs. 1 and 2). 2. Maydl's method of dividing the jejunum, implanting the proximal cut end into the distal portion a few inches from the original line of section, the open end of this section being fixed to the skin (see Fig. 3). 3. The operation which I have performed and which I believe is new. It consists in taking a loop of the beginning of the jejunum just sufficiently long to reach the surface without tension; the two arms of the loop are short-circuited about three or four inches from the surface, the short-circuiting being done either by means of sutures around a decalcified bone bobbin or by sutures alone; personally I prefer the former. A small incision is then made into the top of the loop just large enough to admit a No. 12 Jaques catheter, which is inserted and passed for three inches down the distal arm of the loop; this is fixed to the margin of the incision in the gut by a silk or Pagenstecher's suture and the entrance of the tube into the bowel is further guarded

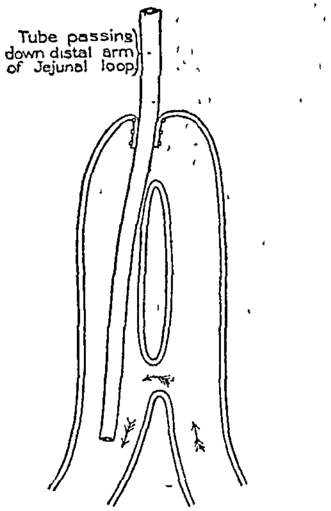
by two purse-string sutures, one over the other. The top of the loop is fixed to the skin by one or two stitches and the wound is closed. The patient can then be fed at once with some peptonised milk and brandy. The whole operation can be done in from 15 to 20 minutes and with very little visceral exposure (see Fig. 4). Should the patient be too ill to bear the little extra time occupied by the short-circuiting the tube may be inserted as directed and surrounded by two or three purse-string sutures, a proceeding which can be accomplished in a few minutes. In this case the loop of bowel must not be brought to the skin but had better be fixed by sutures to the peritoneal margin and the aponeurosis in order to leave part of the lumen of the attached loop within the abdomen for the direct passage onwards of the intestinal fluid with the bile and pancreatic secretion. The following case affords an example of the relief that may follow this operation.

FIG. 4.



Jejunostomy by the author's method, now described.

The patient, a woman, aged 46 years, was sent to see me on April 8th, 1904, when she was suffering great pain, which came on at frequent intervals, and she was vomiting five or six times a day; in fact, whenever she took food it was shortly afterwards vomited, the vomit being at times coffee-ground in character. A tumour in the epigastrium of about the size of a large flat orange could be readily felt and at short intervals the whole stomach became hard and rigid. No enlarged glands could be felt in the groin or above the clavicle. There was no tenderness on pressure and the hard nodular tumour was suggestive of cancer. Though she gave a history of indigestion and loss of health for eight years or even longer the acute symptoms had only existed for six months.

On April 13th the abdomen was opened by a vertical incision through the inner margin of the right rectus, when the stomach was found to be involved in cancer from end to end, and as the glands along the lesser curvature were involved and others could be felt passing up through the opening in the diaphragm and a number also in the great omentum, it was *clearly impossible* to perform gastrectomy and impracticable to do a gastro-enterostomy. A loop of jejunum was therefore brought up and short-circuited by suture over a decalcified bone bobbin and a No. 12 Jaques catheter was inserted as just described. The wound was rapidly closed and the patient was put to bed in good condition, the whole operation only having occupied half an hour or less. A meal of peptonised milk was given at once and repeated every two hours. From the time of operation up to now the vomiting has never been repeated and she has completely lost her pain. *On April 28th, 15 days after* operation, I wrote to Dr. ——: "Mrs. —— has made a good recovery and is now able to take a little food by the mouth, though the feeding is chiefly by the tube. She is free from pain and the tumour is less." The patient returned home on the nineteenth day, having gained flesh and strength. After the patient's return home, on May 17th, I received a reply from Dr. ——: "Mrs. —— is doing wonderfully well. No pain or sickness, and taking as much food as she requires. She is very content and is, I think, gaining flesh and strength, so that the result is even better than you had hoped for and much better than I ever expected. She is very grateful." On Oct. 10th I had a letter *from another practitioner to say that Mrs. —— had come* under his care in North Devon and that she had expressed herself as much improved, though there was a tumour *manifest. The patient survived for a year; ascites and* secondary growths developed.

The case is of interest, not only from the relief afforded by jejunostomy but also as showing the sequence of cancer on ulcer—a not uncommon incidence—and one which might be prevented by timely intervention in the pre-cancerous stage. It is now clearly proved that ulcer of the stomach is a much more serious disease than was once thought and that many cases fail to yield to medical treatment, but I do not think that it is fully recognised how frequently cancer follows on ulcer. In no less than 59·3 per cent. of the cases of cancer of the stomach on which I have operated the history, as in this case, clearly points to antecedent ulcer, the cancer being a later manifestation.

The operation of jejunostomy, which has a mortality of from 10 to 20 per cent., should be very seldom called for and would *not be if the early diagnosis and treatment of* gastric cancer were insisted on; but it must be distinctly recognised that if we intend to do the best for these cases we must make the diagnosis before tumour or coffee-ground vomiting leaves no doubt as to the nature of the ailment. Whenever a patient at or after middle age complains somewhat suddenly of indefinite gastric uneasiness, pain, and vomiting, followed by progressive loss of weight and energy, associated with anæmia, the possibility of cancer of the stomach should be recognised and if no improvement takes place in two or three weeks an exploratory operation is more than justified. Our diagnosis can only be rendered certain by a digital examination, which may be effected through a small incision that can if needful be made under cocaine anæsthesia with little risk. Let us not forget that the early recognition of cancer of the stomach means not only *the probability of relief* but the possibility of cure in a certain proportion of cases.

Park-crescent, W.

THE SECOND DENTITION: ITS MEDICAL ASPECTS.[1]

BY HUBERT ARMSTRONG, M.D., CH.B. VICT., M.D. LIVERP.,

ASSISTANT PHYSICIAN, LIVERPOOL INFIRMARY FOR CHILDREN.

WHEN it is remembered that calcification begins in the case of the first permanent molar during the twenty-fifth week of embryonic life, and that the final eruption of the "wisdom tooth," the last of the permanent set to appear, does not take place till early adulthood, and when in connexion with the lengthy intervening period the importance of a sound dentition to the general health is considered, and *vice versâ* the necessity of good health in the insurance of a sound dentition, it is obvious that the interest in the second dentition is not confined to the dental surgeon but concerns very largely the medical profession generally. It is not necessary here to enter into a description of the normal permanent teeth nor of the dates and the manner of their eruption, matters which are familiar to all of us. A passing reference, however, may be made to the first molar appearing at the sixth to seventh year. A friend informs me that the *extraction of this tooth* for caries and alveolar abscess was the most frequent operation which he was called upon to perform among some hundreds of youths in a naval training school to which he was formerly surgeon-dentist. This emphasises the need of a periodic examination for any early disease of the six-year-old molar and its prompt treatment when discovered. Treatment is unfortunately often postposed until too late through the parents' mistaken idea that since the tooth has not displaced any of the temporary series it consequently belongs to that set. Fortunately, if the tooth has to be extracted its loss is not very greatly felt and the later molars moving forward into its place cause none of the irregularity which attends the too early removal of a milk molar. The subject lends itself naturally to division under three headings.

---

[1] A paper read before the Liverpool Medical Institution on April 27th, 1905.

1. *General or local disease as a cause of faulty dentition.*—(*a*) *General.*—The influence of rickets in retarding the eruption of the milk teeth is a matter of every-day observation and the second dentition may be similarly affected. Doubtless the majority of rickety children have outgrown their complaint and with it the inhibitory influence by the time the permanent teeth are due, but I have seen patients as old as five years who had not yet cut even a single milk tooth, and it is obvious that they would have to compress a good deal into a short period if they were to be up-to-date with their permanent successors. Rickets, too, causes overgrowth of the jaw, with consequent crowding or malposition of the teeth, and occasionally total absence of one or two has the same origin, but these are both of rarer occurrence. The teeth themselves are often tapering and occasionally notched, and the enamel, though smooth, being translucent and thin they are readily prone to decay.

Cretinism exercises in an even more marked degree a similar retarding influence. An excellent example of this is mentioned incidentally in the recently recorded case[2] of a girl nine years old who before treatment had no signs of her second dentition.

Hereditary syphilis is said to have an opposite effect—accelerating the advent of the teeth, but while it is undoubtedly the case with the first dentition I have not been able to satisfy myself that this is not one of those statements passed on from one to another and yet devoid of a reasonable foundation. I do not see enough cases of hereditary syphilis at the right age to justify a complete denial but I may add that several dentists whom I have consulted on the point have likewise refused to commit themselves to a definite opinion. In something under 50 per cent. the teeth are affected in the manner described by Hutchinson and now familiar to us as corroborative evidence of the disease under the name of "Hutchinson's teeth." Shaped like the end of a screwdriver, the upper central incisors, which are the only ones having any diagnostic significance, slope towards (sometimes away from) each other, are dwarfed laterally and vertically, and along their biting edge are hollowed out crescentically through the rapid wearing out and chipping away of the deficient enamel. While ascribed by some to syphilitic alveolar periostitis, by others to the use of mercury, it must not be forgotten that similar deformity may be produced by other disease in infancy and so great an authority as Henoch considered[3] the result one of rickets rather than that of syphilis at all.

Acute disease such as the exanthematous fevers (according to Smale and Colyer[4] particularly measles), severe attacks of bronchitis or pneumonia, and the more chronic disturbances of nutrition due to improper feeding occurring during the first two years of life when calcification is proceeding in the tips of the incisors and canines and the crowns of the first molars leave permanent results in the enamel with a disastrous sequel in the after-history of these teeth. The bicuspids and other molars, in which calcification does not begin till the third year and after, only suffer, and that less frequently, when the illness occurs after that date and then the incisors, &c., escape. The effect is a thinning or even a total disappearance of the enamel, leaving pits and grooves in these "honeycombed" teeth which invariably become the seat of early caries. Here we have an argument, if any now be needed, against the practice of exposing young children to the infection of the exanthemata "in order to get it over" and in favour of maternal or, at any rate, a rational mode of infant feeding. In the earlier attacks the germs of the later teeth may suffer such nutritional changes as to lead to their destruction and consequent absence of the corresponding tooth. Serious disease in infancy is said to cause sometimes crowding and irregularity of the teeth by arresting the growth and development of the jaw, a selective phenomenon of which I have no personal experience. At a later period acute, or even chronic, illness with the exceptions mentioned does not appear to exercise any inhibition on the eruption of the teeth.

Mercury is not often given now to the point of salivation or worse and I agree with those who ascribe defects in the teeth to the constitutional complaint for which the drug may have been exhibited rather than to its use.

(*b*) *Local.*—If retro-nasal adenoids may be considered a local disease and not a manifestation of a diathesis they fall into this category. It is held by many that the consequent mouth breathing, or rather the obstruction to nasal respiration—there are various theories—produces a partial vacuum in the nares which draws upon the palate, causing a vaulted and saddle-shaped arch with crowding of the teeth in the bicuspid region or vaulted and V-shaped arch with protrusion of the incisors. If it be true here is one more indictment in the already overflowing charge-sheet of this disease, but this condition is not found in every case of adenoids and the arched palate is often present without that complication. I know I am on debateable ground but personally I am inclined to lay both the adenoids and the malformation when they are coincident to the account of the lymphatic diathesis. It appears to me that it is chiefly in children of that type that the two conditions are found together and I should term the adenoids a manifestation of the diathesis and the arched palate and crowded teeth a result of general want of "tone" in development and growth. More indisputable and quite preventable local causes of deformity are thumb- and lip-sucking which force outward the upper alveolus with subsequent protrusion of its incisors, and finger-sucking, which acts similarly on the lower jaw, and if for no other reason these habits, together with the use of the "comforter," should be discouraged in young children. Alveolar abscesses in connexion with the milk teeth and too early extraction of the latter lead to irregularities of their permanent successors, the one by interfering with the follicle or growing tooth, the other from the travelling forward of the first molar which ensues leaving no room for the second bicuspid, pointing the lesson that the deciduous teeth need watchful attention as much in the interests of the second dentition as their own. Abscesses also cause hypoplastic defects in the teeth developing in their immediate [illegible]. [illegible] those determined more generally by the exanthemata.

It is beyond the range of my subject to discuss the many congenital abnormalities, such as gemination, enamel nodules, supernumerary teeth, and variations in the number of cusps and roots and their positions, or others due to causes beyond medical control. I pass now to the converse of the first section.

2. *Faulty dentition as a cause of general or local disease.*—The eruption of the permanent teeth is a physiological process and as such ought to be accompanied by few, if any, symptoms beyond the loosening and dropping out of the milk teeth which are displaced. There is no doubt, however, that a little discomfort and restlessness at night, together with a trivial rise in temperature and some [illegible] in the morning the child's pillow is found [illegible] from the mouth or even blood-stained [illegible] the gums, are symptoms which at times accompany [illegible] otherwise normal dentition, and if they are not caused by it I have often been unable to find any other more satisfactory explanation of their presence. Pain, due to stretching of nerve filaments or to small cracks and fissures in the gums, is not uncommon, though never so severe as that of an exposed nerve in a carious tooth. A very frequent source of trouble, and at times quite serious ill-health, is found, particularly in hospital patients, in the incomplete detachment of the remnants of the first dentition. It may be due to simple want of courage in the child or perhaps to some consequence of our latter-day civilisation—for instance, a diminished use of hard food which would assist in dislodging the fragments—but, whatever the cause, it seems to be increasingly frequent to find the milk teeth, and especially the molars, retaining their adhesion to portions of the alveolar mucosa long after the supplanting bicuspid has arrived. Food accumulates and decomposes around these fragments and their short but sharp fangs cut into the cheek, causing ulcers which naturally become septic, while the odour of the breath is extremely offensive. The dread of having a tooth drawn is one of the most firmly implanted characteristics of the human being (of any age!) and I can only ascribe it to this factor, rather than to neglect or indifference, that I am constantly seeing cases of ulcerative

[4] Smale and Colyer: Diseases and Injuries of the Teeth, p. 111.

stomatitis with this origin of weeks' and even months' duration. Needless to say, from the constant swallowing and inhalation of such poisonous stuff as the mouth is harbouring the patients are often seriously ill. The neighbouring glands are swollen and painful but, curiously, rarely suppurate, and further complications may ensue, such as necrosis of the jaw, while in weakly children cancrum oris is said to follow, but in my experience this has never occurred. Fortunately, as a rule, rational treatment results in a very speedy cure. Short of infective stomatitis the same cause in other children sets up the dyspepsia, with anæmia and general debility in its train, which is the common sequel of inefficient mastication whether due to any dental pain or, as in later life, to the absence of the means essential to its performance.

I must recur here to the question of adenoids, because there is another theory of their causation in which the growths are compared with those of weeds in a stagnant ditch. On this assumption, which is the exact reverse of the one previously mentioned, the vaulted palate is the primary mischief and the adenoids secondary. The etiology of adenoids is a wide subject; it will suffice here to have mentioned the two theories which have a bearing on dentition, with the comment that neither carries conviction to my mind.

Dentigerous cysts and odontomes, the latter a very rare form of tumour occurring only in the lower jaw, are the result of perverted development and need merely be glanced at, while an occasional gumboil is not of much moment.

The diseases actually due to the second dentition we find then are not many. The importance, however, of a sound dentition in after-life has already been mentioned. The moral for us is that, whatever the dentist may accomplish, *nature only provides us with one set of teeth for that period*, and that it behoves us therefore to do all in our power during its development and eruption to remove any obstructions in the way of nature's satisfactory performance of her task.

3. *The influence of dentition upon concurrent general disease.*—This, which is not very great, is manifested chiefly in the neuroses, where occasionally one comes across cases upon which dentition has an accelerating or aggravating effect. The most obvious example is in epilepsy, in which one finds that the eruption of the teeth at times initiates the onset and at others increases the frequency of the fits. It must be added, however, that in children with unstable nervous systems very slight irritations may upset the balance and convulsions are never produced in healthy children [illegible] ea may [illegible] pecially [illegible] dicated [illegible] I have [illegible]

Many of the remarks under the last two headings are equally, or even more, applicable to the first dentition and to diseases of the teeth (e.g., caries) when independent of dentition, but I have excluded reference to these as irrelevant to the present discussion.

Liverpool.

TYPHOID FEVER AND PREGNANCY, WITH SPECIAL REFERENCE TO FŒTAL INFECTION.

By H. T. HICKS, F.R.C.S. Eng.,
GYNÆCOLOGICAL REGISTRAR TO GUY'S HOSPITAL;
AND
HERBERT FRENCH, M.D. Oxon., M.R.C.P. Lond.,
MEDICAL REGISTRAR TO GUY'S HOSPITAL.

THE number of published cases in which investigation has been made upon the typhoid reaction in the fœtus is small. The following case is therefore recorded by the kind permission of Dr. W. Hale White, under whose care in Guy's Hospital the patient was.

The patient, aged 24 years, had had three children and two miscarriages. She was seven and a half months pregnant when she became feverish and complained of headache. The fever increased and at the end of a week she was drowsy, with flushed face and furred tongue. The pulse-rate was 110 per minute and two typhoid spots were seen on the abdomen. On the eighth day she was delivered of a live fœtus. There was no difficulty during the labour and there was no excess of hæmorrhage. The infant weighed four pounds and died three quarters of an hour after delivery. The mother seemed much relieved after her labour; her pulse became slower and her fever ran the ordinary course for nearly a fortnight longer. Her temperature ranged between 103° and 104° F. She was frequently sponged. On the twenty-first day of the fever she was worse, her pulse became weak, and she died on the twenty-fourth day of the disease. At the necropsy there were found typical typhoid ulcers throughout the ileum, cæcum, and ascending colon. Involution of the uterus had taken place normally. The placental site looked natural. The necropsy [illegible] after death, revealed [illegible] es were inoculated with [illegible] kidneys, and remained sterile after 48 hours' incubation at 37° C. Unfortunately no bacteriological examination was made of the maternal blood. Widal's test was carried out on the mother and on the child. Blood taken from the mother at the time of labour gave a positive reaction in 5 per cent. solution, a partial in 0·5 per cent. The fœtal serum reaction was negative even at 50 per cent.

Table I. is a summary of the cases of a similar nature that we have found recorded in the literature.

Among the problems which present themselves are the following:—

1. *Are typhoid bacilli transmitted from the mother to the fœtus?*—In ten cases (Nos. 5, 10, 11, 14, 22, 23, 24, 26, 27, and 30 in Table I.) typhoid bacilli were found in the fœtal organs or blood. In Case 26 it is just possible that the fœtus may have been infected after birth. In Bolton's and in Fordyce's cases (Nos. 14 and 5) the fœtuses were born dead. The bacilli must therefore have entered the fœtuses before birth. In 11 cases (Nos. 1, 12, 13, 15, 16, 18, 19, 25, 28, 29, and our own) the typhoid bacilli were looked for in the fœtus and not found. Thus in about half of the published cases of typhoid fever in pregnant women typhoid bacilli have passed into the fœtal blood. In such cases they were probably freely circulating in the mother's blood but we have no proof of this. In future cases particular attention should be paid to the bacteriology of the maternal, as well as of the fœtal, blood.

It is interesting to note that when bacilli have been found in the fœtus delivery has been late in the fever. The times are: Third week, third week, twenty-fourth day, sixth week, fourth week, twenty-ninth day, and twenty-fifth day of a relapse; whereas in those cases in which no bacilli were found the times were comparatively early—viz., tenth day, tenth day, third week, third week, and eighth day from the onset of the mother's fever. It would seem, therefore, that the *duration* of the typhoid fever is an important factor in determining infection of the fœtus. This raises the question whether, in cases where the fœtus is viable, labour should not be induced as early as possible in order to save the child from infection.

2. *Does the typhoid agglutinin occur in the serum of a fœtus born of a mother suffering from typhoid fever?*—That agglutinins do sometimes so occur in the fœtal serum is well established. Positive reactions have been found in seven cases (Nos. 1, 5, 6, 8, 9, 14, and 20 in Table I.).

3. *Can the typhoid serum reaction occur in the fœtus in which no bacilli have been found?*—The evidence that this can be so is slender. Out of the seven cases in which a positive serum reaction was obtained in the fœtus three only were examined for bacteria. In two (Nos. 5 and 14) typhoid bacilli were found. In [illegible] ooked for but not found. This is [illegible] It is so important that we give [illegible] his own words:—

> [illegible] collapsus et elle succombe a [illegible] s sont [illegible] ment. [illegible] ment [illegible] sang [illegible] ganes [illegible] uvoir [illegible] d'une [illegible] épart [illegible] de 200. Le liquide amniotique a également un pouvoir de 200.

TABLE I.—TABLE OF RECORDED CASES OF EXAMINATION FOR TYPHOID BACILLI OR FOR WIDAL'S TEST IN FŒTUSES BORN OF MOTHERS SUFFERING FROM TYPHOID FEVER.

Number of case.	Name of observer.	Month of pregnancy.	Fate of mother.	Fate of fœtus.	Widal's reaction in the mother.	In the fœtus.	
						Bacilli in tissues.	Widal's reaction.
1	Etienne, G.[14]	5	Died.	Taken out at necropsy on fifteenth day of fever.	Positive 1 in 150.	Looked for and not found.	Positive 1 in 200.
2	Dogliotti.[8]	—	—	—	Positive.	Not examined.	Negative
3	Planchu and Gallavardin.[25]	8½	Lived.	Born on ninth day of fever; lived.	,,	,,	,,
4	,, [26]	6	,,	Born alive on thirteenth day of fever; died.	,,	,,	,,
5	Fordyce [15]	5	Died.	Born dead in sixth week.	,,	Present.	Positive.
6	Chambrelent.[6]	8	Lived.	Lived. No record of day of fever when born.	,,	Not examined.	,,
7	,, [7]	8	,,	Born on fourth day of fever; lived.	,,	,,	Negative.
8	Griffiths.[20]	9	,,	Born after three weeks' fever; lived.	,,	,,	Positive.
9	Mosso and Danic.[24]	—	,,	—	,,	,,	(?) ,,
10	Freund and Levi.[18]	5	,,	Born alive in fourth week of fever; died.	Not examined.	Present.	Not examined.
11	Etienne, G.[13]	5	—	Born dead on twenty-ninth day of fever.	—	,,	,,
12	Bolton.[5]	3	Died.	Born dead during third week of fever.	Positive.	Looked for and not found.	Negative.
13	,, [5]	8	Lived.	Born alive during third week; died in 12 hours.	,,	,,	,,
14	,, [5]	5	,,	Born dead on twenty-fifth day of relapse.	,,	Present.	Positive.
15	Rous and Lacroix.[29]	8	,,	Twins, born alive on tenth day of fever; died in four days.	,,	Looked for and not found.	Negative.
16	,, [29]	8	,,	Born alive on tenth day of fever; died in three days.	,,	,,	,,
17	Batty Shaw.[4]	9	,,	The mother had typhoid fever at fourth to fifth month of pregnancy; the pregnancy continued and the child was born alive at term, and was fed upon the breast.	Positive at time of fever; positive at time child was born.	Not examined.	Negative, even after five weeks' feeding on mother's milk.
18	Kirton.[23]	6	—	Dead; no details.	Positive.	Looked for and not found.	Negative.
19	,, [23]	9	—	Dead; no details.	,,	,,	,,
20	,, [23]	9	—	—	—	Not examined.	Positive.
21	Stengel.[30]	—	—	—	—	,,	Negative.
	Earlier cases in which the details are incomplete; investigated before the days of Widal's serum test.						
22	Eberth.[11]	—	—	Born dead, third week of fever.	Not examined.	Present.	Not examined
23	Hildebrandt.[21]	6½	—	Born dead on twenty-second day of fever.	,,	,,	,,
24	Giglio.[19]	—	—	—	,,	,,	,,
25	Frascani.[17]	—	—	—	,,	Looked for and not found.	,,
26	Janiszeski.[22]	—	—	Infant, premature; lived 15 days.	,,	Present after death.	,,
27	Durk.[9]	—	—	—	,,	Present.	,,
28	Resinelli.[28]	—	—	—	,,	Looked for and not found.	,,
29	Fraenkel and Kiderlein.[16]	5	Died.	Dead; born seventeenth day.	,,	,,	,,
30	Érnst.[12]	9	Lived.	Date of delivery uncertain. The child developed a spotty rash suggestive of typhoid fever; died on the fourth day after birth. No intestinal lesions.	,,	Present.	,,

The figures after the observers' names indicate the numbers of the references at the end of the paper.

The occurrence of agglutinins without bacteria in the fœtus appears to us contrary to expectation. It is a point requiring careful and repeated confirmation. If true, the deduction must be that a positive Widal's reaction in the fœtus is no proof that the fœtus has, or has had, typhoid fever. It further raises the question:—

4. *How does the fœtus acquire agglutinin?*—Since it is well established that typhoid bacilli are sometimes found in the fœtus it would be reasonable to expect that the fœtal tissues, reacting to the bacillary invasion, would produce their own agglutinins, the fœtus behaving as though it were an independent individual. If bacilli were always found in the fœtal tissues when the fœtal serum gave a positive reaction, as in Fordyce's and in Bolton's cases (Nos. 5 and 14), there would be ground for presuming that the fœtus always produced its own agglutinins in this way. Etienne's case, if true, seems to support the opposite view—namely, that the serum reaction can occur in the fœtus without bacilli being present. It is a most important case but it needs confirmation. If confirmed it would show that agglutinin may occur in the fœtus without bacillary infection. If this be the case there are two possibilities: either the fœtus receives the agglutinin directly from the mother across the placenta; or, the fœtus reacts to the maternal bacillary infection, by producing its own agglutinins in response to stimulation by maternal toxins.

The passive transmission of the agglutinin from the mother to the fœtus would seem possible, since we know that the virus of measles,[1] of variola,[2] and of syphilis can pass, and also soluble drugs[3] such as mercury, potassium iodide, alcohol, and chloroform. If, however, this be the usual method by which the fœtus obtains its agglutinins it is difficult to explain (1) why the fœtal serum reactions should be absent in so many cases (viz., Nos. 2, 3, 4, 7, 12, 13, 15, 16, 17, 18, 19, and our own), in all of which the maternal reactions were positive; (2) why, in a case such

as that given by Batty Shaw (No. 1
remained in utero for four months after
of typhoid fever, should give a negati
mother's serum gave a strong reactior
the fever and also at the time of the ch

We would further draw attention t
negative fœtal results have nearly all occurred in the cases in which early delivery had taken place. In the negative cases the times were: ninth day, fourth day, thirteenth day, tenth day, tenth day, eighth day, third week, and third week of the fever; whilst positive results were obtained at the *sixth week, third week, third month, and twenty-fifth day.* The times were appreciably the longer when a positive result was obtained. It is difficult to see why there should be this delay in the passage of agglutinins if the fœtus receives them from the mother; unless the placenta can be supposed to exert a *temporary* "barrier-action"[27] *against the passage* across it of agglutinins but ultimately allows them to pass. It seems equally reasonable to suppose that the fœtus produces its own agglutinins. It is a matter of regret that all the cases of positive serum reaction in the fœtus have not been bacteriologically examined.

The effect of pregnancy upon the mother who has typhoid fever.—Typhoid fever occurring during pregnancy does not affect the prognosis or alter the course of the disease. The results in the seven cases that have occurred in Guy's Hospital over a period of 28 years are given in Table II.

TABLE II.

Age of mother.	Month of pregnancy.	Fate of mother.	Fate of fœtus.
24	8	Died.	Born alive at *eighth day of fever.* Died in three-quarters of an hour.
26	5	Recovered.	Went to term. Born alive and lived.
21	2½	"	Abortion on seventeenth day of fever.
24	3½	"	" twenty-sixth " "
24	4	"	" fourteenth " "
20	8½	"	Labour on fourth day of fever. Child lived.
31	4	"	Abortion during fourth week of fever.

The death-rate was 14 per cent. Vinay[31] gives the mortality at 17 per cent. Duynot[10] gives six deaths in 36 cases, a mortality of 16 per cent. These figures do not differ widely from those given by the Metropolitan Asylums Board for all cases.

The effect of typhoid fever in the mother on the pregnancy.—The effect of enteric fever on the pregnancy is bad. In the majority of the cases abortion or premature labour takes place. This was so in six of the seven cases in Guy's Hospital—i.e., 85 per cent. Vinay gives two-thirds of abortions. Martinet's figures are 66 abortions in 109 cases. Penot[25] gives 65 per cent. of abortions. The delivery is most often easy and the patient experiences considerable relief. The uterus involutes just as if there were no maternal illness. The fœtus, even if viable, is often born dead or dies soon after birth. As we have suggested, it is possible that this heavy mortality amongst viable fœtuses might be reduced by the induction of premature labour in the earliest stage of the fever. Such induction would seem to be justifiable in the interests of the child when the prognosis for the mother is apparently so little influenced by labour.

Our best thanks are due to Dr. Hale White both for leave to publish the case and for his helpful criticism of our paper; we also thank Dr. J. W. H. Eyre heartily for his careful bacteriological examinations.

THE ACTION OF YEAST IN TUBERCULOSIS AND ITS INFLUENCE ON THE OPSONIC INDEX.

BY WILLIAM R. HUGGARD, M.A., M.D., M.CH. R.U.I.,
F.R.C.P. LOND.,

AND

EGBERT C. MORLAND, B.SC., M.B. LOND.

FOR the last ten or twelve years yeast and nuclein, which is sometimes held—though without sufficient warrant—to be *its active therapeutic constituent*, have been employed by many observers in the treatment of various bacterial diseases. The idea at the bottom of this mode of treatment is twofold. Nuclein *is a chief constituent of* the *white* blood *cells* and the administration of nuclein is commonly supposed to be followed, after a preliminary drop, by an increase in the number of these *cells*. In *addition to this, nuclein has a* bactericidal action. From these facts the inference was at hand that nuclein would reinforce the leucocytes in number and in activity and so help them in their struggle with invaders and that at the same time it would render the country *less suitable for the support of the intruders.*

In spite of the seeming soundness of the theory, and in spite of much favourable clinical observation, neither yeast nor nuclein has ever come into general use. Neither yeast nor nuclein is even mentioned in Hale White's admirable "Text-book of Pharmacology and Therapeutics" (1901); and Sir William Whitla,[1] speaking of nuclein, says: "Glowing reports were *published of the improvements* and even cures of tubercular disease of the lung. Notwithstanding these glowing accounts this drug, which was hailed as an 'essence of life,' is rapidly falling into disuse." In the exaggerated language quoted by Whitla we have doubtless one *great reason* for the neglect of the drug. Where the expectations are too high disappointment is bound to follow. Pure cultures *of yeast administered* hypodermically were strongly advocated a few years ago by de Backer of Paris; and his views, more concisely expounded, were put before the profession in England by Dr. H. Manders in his extremely interesting book on "The Ferment Treatment of Cancer and Tuberculosis" (1898).

One of us became acquainted with some of the virtues of yeast nearly 25 years ago. He had been suffering for about a year from successive crops of boils, against which various remedies had been tried *in vain*, when he was advised by Dr. (now Sir) Stephen Mackenzie to take yeast. He took yeast; a tablespoonful in milk daily. The boils in progress at the time became less severe and were not followed by a fresh crop. From that time on he has used yeast in furunculosis and always with good results. Some of the patients also were suffering from tuberculosis and not uncommonly while *taking yeast* they *appeared* to improve generally. From this point of view systematic observations have been made for the *last* two *years* on the influence, if any, of yeast taken internally on tuberculosis. The cases at first selected were chronic cases in which the patient had either "stuck in the mud" or was losing ground. Three or four advanced cases which were going downhill were also included in the observations. The results in some cases were striking, in some cases encouraging, in others almost *nil*. In *no* case was there any bad effect but some patients left off the drug because they disliked the taste of it or thought that it disagreed with them. All the cases, even those whose downward course was not arrested, appeared to derive some benefit from the remedy. In most cases the downward course either became less rapid or was arrested and the stationary cases improved. On the whole the results were good enough to lead to a more extended trial. 36 patients were under this treatment for periods varying from a fortnight to about 12 months. Besides these there were about half a dozen who took the remedy for less than a fortnight but who discontinued it for one reason or another, such as flatulence, dislike of the taste, or disgust at the smell of the yeast. The clinical outcome of all the observations is that some improvement was noted in almost every case where the remedy was taken steadily for at least a month, though in many cases improvement appeared much earlier. In all but one case tubercle bacilli were present when the yeast treatment was begun. For the purposes of the present paper the cases may be arranged as follows. (*a*) One case without tubercle bacilli in the sputum. (*b*) Five cases in which tubercle bacilli disappeared and the disease became seemingly arrested while under yeast treatment. (*c*) Seven cases in which the disease is tending towards arrest but in which tubercle bacilli have not yet disappeared. In all the foregoing cases recovery would be almost certain in the absence of any treatment not absolutely harmful, but yeast appeared to quicken the rate of improvement. (*d*) 11 cases of medium severity and of doubtful prognosis, the patients either losing ground or barely holding their own when the yeast was begun. All but one improved more or less; seven improved both locally and generally; two improved generally but not locally; one remained practically unchanged both generally and locally, though the opsonic index rose; in one (detailed more fully below) renal tuberculosis and albuminuria were found. In six of the cases there was a diminution of tubercle bacilli; in three of the cases an increase; and in two cases the numbers were unchanged. In two cases renal as well as pulmonary tuberculosis was present. In one of these cases the patient took urotropin for a considerable time before the yeast, but without noticeable effect on the tubercle bacilli. The urotropin was continued with the yeast. Tubercle bacilli have now almost disappeared. In the other of these two cases there was laryngeal as well as pulmonary tuberculosis and during the yeast treatment renal tuberculosis and albuminuria were discovered after the appearance of gouty pains (pains with tenderness in the joints of the hands and feet). The urine was normal in quantity and in specific gravity but contained a large quantity of albumin and a few granular casts. The patient felt well and seemed in better health than previously. The state of the lungs and of the larynx improved at the same time. (*e*) 12 advanced cases of bad prognosis, nine with more or less pyrexia. All appeared to benefit in general health to some extent, at least for a time. Seven improved considerably in local as well as in general condition and show some promise of reaching a stage of tolerance or quiescence. In two there was no material change in the local condition. In one case excavation which had already been extensive seemed to go on even more rapidly, in spite of some improvement in the general health. Two of the patients died subsequently.

[1] Sir William Whitla: Elements of Pharmacy, Materia Medica, and Therapeutics. Eighth edition, 1903, p. 547.

The masterly researches of Wright and his fellow-workers have recently placed in the hands of physicians a new test as to the course that a case of tuberculosis is taking. This test is the opsonic index. It shows the degree to which the serum of a person's blood prepares tubercle bacilli for being taken up and digested by normal white blood corpuscles; and, apart from disturbing influences, appears to be fairly constant. Two of Wright's papers especially will repay study by all who are interested in the subject: "A Lecture on the Inoculation Treatment of Tuberculosis"[2] and "On the Action Exerted upon the Tubercle Bacillus by Human Blood Fluids and on the Elaboration of Protective Elements in the Human Organism in Response to Inoculations of a Tubercle Vaccine"[3] (by A. E. Wright and S. R. Douglas). One important point brought out by Wright is that tuberculin treatment, unless under the guidance of this test, is not unlikely to be attended by evil results. The effect of a tuberculin injection is first a fall and then a rise in the protective elements of the blood, but if the injection is renewed before the rise has taken place the patient's resistance becomes progressively lower. Wright's researches suggested the desirability of testing the influence of the yeast treatment on the blood and observations to this effect were begun about the middle of January last. An interval of a fortnight or more was generally left between two examinations. Out of 25 cases available for comparison four had been under the yeast treatment for at least two or three months before the first examination was made. In three of these four cases the opsonic index was extremely high—over unity, that is, higher than in the case of a perfectly healthy person. . . .7— that is, rather above tl . Of the whole 25 cases, in ie it remained unchanged. nch the opsonic index fell, in three there had been an intercurrent ailment—influenza in two cases and febrile disturbance in the third. In one of these three cases there was a subsequent rise to about . . In the other case in which the opsonic in . explanation suggests itself. There was . . the patient's general condition, but the l ined practically unchanged, though there was some diminution in the amount of sputum. The following table shows the opsonic index at successive examinations in these 25 patients, the number of days from the first to the last observation, the rise or fall of the index, and the decrease or increase of tubercle bacilli in the sputum:—

Table of Opsonic Index in 25 Unselected Cases of Tuberculosis during Administration of Yeast.

Serial number.	Opsonic index. (Decimal point omitted for convenience.)	Number of days between first and last observation.	Rise (+) or fall (−) of index.	Decrease (−)* or increase (+) of tuberculous bacilli.

* The last column gives the decrease or inc
scale of tubercle bacilli in the sputum during
thus, an increase from No. 1 to 3 or from No. 5 to
a corresponding decrease by −2.

Observations on the foregoing table.—No. 1 had slight febrile disturbance between the first and the second examination. No. 6 had been taking yeast off and on for about a year. No. 12 had recurrent attacks of influenza between the two examinations. No. 17 had been taking yeast before the first examination; had taken it also last winter; and had an attack of influenza between the two blood examinations. No. 18 had been taking yeast before the first examination. The opsonic index was examined in many other persons, some well and some suffering from tuberculosis but not taking yeast, and some interesting facts came out. Persons recovering from tuberculosis showed, in four or five instances,

FIG 3

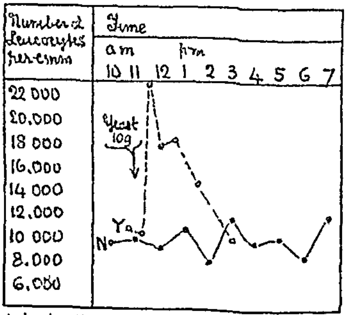

Chart showing the normal daily variation in the leucocyte count (N) and that following the administration of a single dose of yeast (Y)

were made at first every half hour The diagram shows that in the first half hour the number of leucocytes was more than doubled In the second half hour a fall equal to nearly half the rise took place Then with a slight fluctuation the fall continued until in about three and a half hours the number of leucocytes was rather below the level when the dose was taken A noteworthy circumstance is that the blood of persons (suffering from tuberculosis) who had taken yeast for some time yielded on the average lower leucocyte counts than did the blood of persons not taking yeast as is shown in the following little table

Average Leucocyte Count

28 counts of persons not taking yeast	10 800 leucocytes per c mm
60 „ „ taking yeast	7 800 leucocytes per c mm

Some patients were taking benzosol, quinine terpin hydrate, calcium glycerophosphate, or phenacetin, alone or in combination, before beginning the yeast treatment, and then in order to make as little change as possible, these were continued with the yeast—at any rate, for a time

As regards the general effects of the yeast some patients did not notice any influence whatever Some felt a sense of well being, two or three had a feeling of exhilaration Several patients said that their appetite and digestion were better on taking yeast A few complained of flatulence, less noticeable or absent when the yeast was taken on an empty stomach Two or three patients said that under its use the bowels acted more regularly Two or three patients found that owing to the taste or smell it caused a feeling of nausea or disgust and in these cases it was of course dropped at once In two or three cases gouty or rheumatic pains were complained of after yeast had been taken for some little time The discove
in one person who
all the other case
evidence of renal n
time before beginning the yeast treatment had had albuminuria with granular casts and another also had well marked renal tuberculosis before the treatment was begun Yeast did not appear to have any influence on the temperature of patients suffering from a febrile tendency Influenza in a mild form occurred in two or three patients while they were taking yeast which therefore can hardly be looked on as a preventive

The yeast employed has been of three or four different kinds Common German yeast or *presshefe* was most generally used Ordinary
or four patients while in
Swiss proprietary yeast wa
'Ferment de Raisin a Fr
used by three patients In the earlier observations the dose of yeast was generally a piece of the size of a filbert—about two or three grammes—once daily In most of the later observations a larger dose was employed, a piece of the size of a walnut was taken twice a day The dose was usually taken in cold or tepid milk or in water In view of the drop
c index the question occurs
be minimised and the sub
sequent ent dosage or by a different interval between the doses The plan of giving one dose of ten grammes—a piece of the size of a walnut—every five days is at present on trial

A few words must be said about the composition of yeast[4] In fresh yeast the proportion of water varies from 75 to 83 per cent According to
yeast, dried consists of
parts, proteid bodies—
stable phosphorised bodie
by subacetate of lead two parts, fatty matter, five parts, extractive matters (leucine, tyrosine guanin, xanthin), four parts and ash seven parts The various substances contained in the ash vary according to different analysts and specimens within the following limits potash 23 3 to 39 5 per cent, soda, 0 5 to 2 5 per cent, magnesia, 4 1 to 6 5 per cent, lime, 1 0 to 7 6 per cent, phosphoric acid, 44 8 to 59 4 per cent, sulphuric acid 0 3 to 6 4 per cent, silicic acid 0 9 to 1 9 per cent, and chlorine, 0 03 to 0 1 per cent Of the proteid bodies in yeast the nucleins only have been carefully studied. In an analysis of beer yeast by Stutzer nitrogen amounted to 8 65 per cent. and of this rather more

---

[4] The account of i taken chiefly from J Konig's Chemi in d Genussmittel Zweiter Band Viert

[5] Cited in Morat et Doyon Fonctions Elémentaires, 1904, vol. I. p 85.

than one fourth (2·65 per cent.) came from the nucleins. The cellulose and gum of yeast appear to consist largely of glycogen. König cites Clautrian and Laurent as estimating the glycogen in dried yeast at 31 per cent. and at 32·6 per cent. respectively. The amount appears, however, to vary a good deal according to the life period of the yeast; and Harden and Young are cited in Richet's Dictionary[6] as having found the average amount of glycogen in yeast only about 2 per cent.

A great number of different enzymes are contained in yeast. They are classified by König into four groups, according as they are hydrolytic or oxidising, reducing, or fermentative. The hydrolytic enzymes are subdivided according as they are sugar-splitting, proteolytic, or coagulating. Besides the constituents of yeast itself the products to which it gives rise have to be borne in mind. These products are twofold; the products of fermentation and the products of the metabolism of the living cells. The products of fermentation include carbonic acid and various alcohols; amongst which amyl-, propyl-, isobutyl-alcohols, aldehyde, and furfural have been found. Amongst the products of metabolism glycerine and succinic acid appear to be the most important. The products of fermentation and probably also the products of metabolism are considerably influenced by various circumstances besides the particular variety of saccharomyces. Thus temperature, the nature and composition of the fluid, its degree of concentration, the presence of certain nitrogenous substances, such as asparagin, pepton, or ammonium salts—all may influence the result.

Many interesting problems for future investigation are suggested by the facts already brought out. Is the action of yeast on the opsonic index due to nuclein, to an enzyme, to the products of metabolism or of fermentation after ingestion, or to the joint action of all? The rise in the number of leucocytes appears to be coincident with a fall in the opsonic index; and a final lower level in the number of leucocytes under the prolonged administration of yeast appears to correspond with a rise in the opsonic index. What is the explanation? Is the activity of the leucocytes themselves in any way modified by yeast or by its products? How long does the opsonic index remain up after yeast has been stopped? The clinical material for this paper was furnished by one of us (W. R. H.) and the bacteriological material by the other (E. C. M.).

Davos-Platz, Switzerland.

A NOTE ON THE TREATMENT OF THE TOXÆMIC SYMPTOMS IN SCARLET FEVER.

BY A. KNYVETT GORDON, M.B. CANTAB.,
LECTURER ON INFECTIOUS DISEASES IN THE UNIVERSITY OF MANCHESTER; MEDICAL SUPERINTENDENT OF MONSALL HOSPITAL.

THE cases of scarlet fever which occur most commonly in practice may, roughly speaking, be divided into three classes or types and this distinction is not invalidated by the fact that mixtures of these are occasionally met with. There is the simple variety, where the attack presents no special distinguishing features and is not at any time severe; the pyrexia subsides, as the faucial inflammation resolves, at the end of the first week or thereabouts, and, with the exception perhaps of a transient otorrhœa, there is no complication or sequel of note. In this type little treatment, except the preservation of asepsis in the surroundings, and accessible organs, of the patient, is needed for the disease itself, though symptoms may occasionally require relief. But a patient may be severely ill with scarlet fever in one of two ways: he may have an intense faucial inflammation which, instead of subsiding in due course, progresses. The ulceration of the tonsils or palate becomes deeper, sloughing occurs, the mouth, the nose, and the naso-pharynx are excoriated and filled with foul secretion, and from these cavities absorption takes place with the production of a general septicæmia which usually corresponds in intensity to the extent of the faucial affection. Otorrhœa, after often running a protracted course, almost certainly follows, and late nephritis is not uncommon. To this type, which is more common in isolation hospital practice by virtue of its being more frequently found in ill-nourished or uncleanly children, the convenient, though possibly somewhat inaccurate, name of "septic scarlet fever" has been given. It is, at all events, a better term than its predecessor "scarlatina anginosa." Of this type I do not propose here to speak.

In the third class the symptoms are very different. Here the patient receives a large dose of the scarlatinal poison, whatever this may be, at the onset. In some cases death occurs before the rash has appeared and a fatal termination within 24 hours of the first sign of the eruption is not uncommon. The patient is semi-comatose, cyanosed, and is evidently intoxicated; the pulse is rapid and feeble, and the respiratory-rate is so quickened as to suggest the presence of a pneumonia; the pupils are dilated, and there is low muttering delirium. To this type the appropriate name of "toxic scarlet fever" has been given, and this, again, is an improvement on the term "malignant" which usually denoted a case of this sort, but which was also loosely applied to any that appeared to be moribund or intensely ill. The frequency of this type certainly varies within wide limits. It appears to be more common in certain districts than in others—apart, that is, from epidemic prevalence. It is certainly, within my own experience, more common, for instance, in Manchester than in London. It also seems to occur more frequently in certain epidemics than in others; now and again it will crop up in a small country village or in a single spot in a town. It is difficult, therefore, to state its frequency with any accuracy. At Monsall Hospital I have met with 55 cases which I should describe as toxic out of 3403 consecutive admissions. Clinically it is a very fatal type of the disease. My own belief is that in the absence of adequate specific treatment about 80 per cent. die either in the acute stage or from subsequent prolonged septicæmia or pyæmia, for if the acute stage is passed these cases become "septic" like the preceding type.

In the absence of any accurate knowledge of the scarlatinal toxin, or toxins, all treatment must be empirical. Perhaps the more common plan is to give large doses of alcohol, digitalis, carbonate of ammonia, strychnine, &c., to which might be added, more recently, the cold bath, but I cannot say that I have ever seen any, or all, of these do the slightest good, though I have had the opportunity of trying them fairly thoroughly. It was, of course, obvious from the first that the only successful treatment of these cases could be by the administration of an antitoxin, if such could be found, and in 1897 I described a case of this type that had recovered after a small dose of some antistreptococcic serum obtained from the Pasteur Institute: this was a monovalent serum. Consequently I gave this serum in other toxic and in some septic cases but I never obtained any further good results with it. In one case under the care of a colleague it certainly seemed to do harm. At all events, it seemed to me that the chance of hitting off, so to speak, the particular streptococcal toxin with a monovalent serum was a small one.

Two years ago, however, I commenced to work with a polyvalent antistreptococcic serum prepared by Dr. W. Dowson, the director of the Wellcome Research Laboratories, and which then had its origin from the following streptococci: streptococcus erysipelatos, No. 1; streptococcus erysipelatos, No. 2; streptococcus pyogenes (empyema); streptococcus pyogenes (puerperal fever); streptococcus pyogenes (wound infection); streptococcus from a case of septic tonsillitis; and streptococcus "aus chorea." To what extent it was a bactericidal, and to what an antitoxic, serum is uncertain and it will be seen that it did not at that time contain any scarlatinal elements at all. Various other streptococci were, I understand, added from time to time, but until 1904 none of these had been isolated from cases that could have been scarlatinal in origin. At that time a streptococcus was introduced from a patient who may possibly have had scarlet fever but in whom the diagnosis was doubtful. Dr. Dowson, in order to enable me to test this point, very kindly sent me some serum prepared from this last streptococcus only and I found that its injection had no ascertainable effect whatever, though it was given early in the course of the disease and in large doses. In all probability, therefore, we can exclude this streptococcus from any participation in the results which followed the use of the combined serum.

As regards the bacteriology of these cases it is a significant fact that in the laboratory here, where a large number of cultures from scarlatinal patients are examined—and I may say, in passing, that a culture from the throat, the nose, and the ears of every scarlatinal patient is taken at least once during the patient's stay in hospital—it is exceedingly uncommon for a pure culture of any organism to be met with, though in the case of diphtheria this occurs quite frequently. I am informed by Professor S. Delépine also that he has had a similar experience in the Public Health Laboratory. In all the cases to be described streptococci of one kind or another were present in mixed culture. So far as this goes it is significant, as pointing to the improbability that the phenomena of scarlet fever are due to a pure infection with any organism. Whatever scarlet fever be in theory, it is in practice a mixed infection.

---

[6] Richet's Dictionnaire de Physiologie, vol. vii., 1905, p. 308.

This serum, then, was given to 50 out of the 55 toxic cases previously mentioned, and it was, in fact, only withheld in five who were *in articulo mortis* on admission. It was, in addition, administered to five others that were really examples of the mixed (septic and toxic) type. The dose varied considerably. At first 20 or 40 cubic centimetres only were injected but later doses of 50 or 100 cubic centimetres were employed. In the majority of instances the whole amount was given in one injection immediately upon the admission of the patient, which was as a rule on the second or third day of the illness. Of these 55 injected cases 13 died—a mortality of about 23½ per cent. A reduction was also apparent in the general scarlatinal mortality of the hospital, which was in 1902 6·1 per cent. and in 1903 (the first year in which the serum was employed) 4·7 per cent. and in 1904, with increasing use of the serum, 3·1 per cent. I do not wish to press this statistical argument unduly, as so many factors have to be taken into consideration which cannot be recorded statistically but which are capable of influencing the result, but there can be no doubt that life has been saved by the use of the serum in these toxic cases.

The whole subject of serum therapy in scarlet fever is empirical. We do not know what the organism of scarlet fever is or even if the disease is due to one germ or to many; we cannot reproduce the disease in an animal and we have not, in theory, an antitoxin for it. To record a dose in terms of so many cubic centimetres is valueless, for no antistreptococcic serum can be standardised. Many attempts have been made to obtain a serum from scarlatinal cases only. Moser's is perhaps the best known of these but it is unfortunately not obtainable commercially and its use is therefore restricted. I hope myself to publish later, in conjunction with Dr. Dowson, some further work on this point, but in the meantime I have communicated this preliminary note in order that a remedy which appears to have a decided clinical value, and which can be easily obtained, should have from others the further trial which I believe it merits.

I have never observed any ill-effects from the serum except a transient erythema, which is not, as far as my experience goes, so irksome to the patient as that met with after antidiphtheritic serum. The larger dose of 100 cubic centimetres is, in my opinion, more useful than the smaller ones and it is advisable to give all that is going to be administered in one injection. I have never seen any effect follow a repeated dose. Obviously, the serum should be given as early as possible in the course of the attack.

INNOMINATE ANEURYSM; SIMULTANEOUS LIGATURE OF RIGHT CAROTID AND SUBCLAVIAN ARTERIES; RECOVERY.

BY H. NASON DUNN, M.B., B.CH. DUB.,
MAJOR, R.A.M.C.

THE patient, an ex-soldier, aged 40 years, single, contracted syphilis in 1886, when he was under treatment for some weeks. Early in July, 1904, he suffered from severe neuralgic pains radiating from the right side of the chest to the back of the head and extending into the right shoulder. He attended the out-patient department of the Royal Arsenal Hospital, Woolwich, but no physical signs were apparently present at the time. On Sept. 27th, the pains being more severe, he again presented himself at the hospital and when seen by me a well-marked pulsatile swelling occupied the episternal notch and extended from the sternal origin of the left sterno-mastoid muscle to the junction of the inner and middle thirds of the right clavicle. The tumour measured three and a half inches laterally and projected upwards above the clavicle for one and a quarter inches, the lower margin being ill-defined, well-marked expansile pulsation with a systolic murmur being [illegible] displaced to the left; dysphagia [illegible] dyspnœa on exertion or assuming [illegible] complained of. He also suffered from severe pains along the right side of the head and neck and the right shoulder and arm, the radial pulse on the right being also smaller than that on the left side and its rhythm somewhat delayed. His voice was reduced to a whisper and his cough was "brassy" in character, the right vocal cord being fixed and motionless, due to direct pressure on the recurrent laryngeal nerve, but "tracheal tugging" was not observed.

As the man was exceedingly ill and the tumour was enlarging rapidly Mr. L. A. Bidwell of the West London Hospital kindly saw him and confirmed the diagnosis of innominate aneurysm. The patient was admitted to the hospital and was put on a modified Tufnell's diet and large doses of potassium iodide (30 to 50 grains) were administered three times a day. An attempt to get an x ray photograph of the tumour was unsuccessful. For the first few weeks after admission marked improvement, due to the rest and dieting, took place; but as the tumour subsequently increased in size operation was decided upon. With Mr. Bidwell's assistance the right common carotid was ligatured above the omohyoid muscle and the subclavian was tied in its third stage. The patient being a man with a long spare neck there was no difficulty about the operation, the subclavian being easily reached below the clavicle, as suggested by Mr. Bidwell, by elevating the shoulder. Both arteries were apparently healthy at the site of ligature; double strands of silk were the material used. Both wounds, with the exception of one small stitch point, healed without suppuration. The patient's temperature rose to 99·6° F. on the day following the operation and fluctuated between that and normal until the fourteenth day, when it finally settled down. He complained of severe pain along the right arm but no œdema took place nor did any head symptoms occur. Immediately after ligature of the arteries a decided diminution of the sac took place and that portion in the episternal notch became firmer and less expansile, but subsequently the remainder of the tumour enlarged slightly upwards and outwards and pulsated somewhat more freely than before ligature.

The following was the patient's condition on March 29th, 51 days after operation. That portion of the sac in the episternal notch had consolidated and felt firm to the touch although faint pulsation was still felt and the sac itself was tender on pressure. His voice had much improved but the cough was still "brassy" and paralysis of the right cord still persisted. Some difficulty in swallowing solids continued but pain had disappeared. He was discharged from hospital on April 7th at his own request.

On May 1st, 85 days after the operation, the patient was recommended for light employment. He now walks about one and a half miles to and from his work daily without dyspnœa and can follow his occupation of cleaning tools at the bench without pain or inconvenience of any sort except slight fatigue of the right arm and shoulder. The tumour has shrunk considerably and is firmer and less expansile, measuring two and three quarter inches laterally and extending for three quarters of an inch above the clavicle. Paralysis of his right vocal cord is still present and on inspection there is a slight fulness immediately above the sternal end of the right clavicle and the external jugular vein is more prominent than that on the opposite side. No temporal pulse is to be felt although a faint radial pulse is present and coldness and slight weakness of the right arm remain.

The following statistics taken from records available at the Medical Graduates' College, London, may be of interest. Mr. Bennett May in THE LANCET[1] reported the results of 35 cases of distal ligature of the carotid and subclavian for innominate aneurysm—of these, in 29 both arteries were ligatured simultaneously and six consecutively. 23 died, death being hastened by the operation; in six the disease was not checked and six were practically cured. He also reported 29 cases in which the common carotid alone was tied and of these 19 died from the operation or soon after; in six the disease was not arrested and four were practically cured or showed marked improvement. I have also been able to find accounts of ten other cases of simultaneous distal ligature of both arteries reported in the medical journals; in five the sac became firmer and smaller and the patients were able to do light work; in four death occurred in periods varying from ten days to one year (two from lung trouble and one as the result of hemiplegia); in one the condition was relieved but not cured; in no case, however, was there complete consolidation of the sac, although in one it was reported to have shrunk to the size of a walnut.

Royal Arsenal, Woolwich.

COEXISTENCE OF CYSTIC MESOMETRIUM AND TUBAL PREGNANCY.[1]

BY F. J. STRONG HEANEY, M.A., M.D. DUB., F.R.C.S. IREL.,
HONORARY SURGEON TO THE VICTORIA HOSPITAL, BLACKPOOL.

THE patient, a woman, aged 26 years, came to the out-patient department complaining of pain in the left iliac region of about two weeks' duration. She had been married seven years and had one child, aged five years. Following this pregnancy and up to the time of my seeing her menstruation had been regular with the exception of one short period ten months previously when about a week after menstruating she was seized with acute abdominal pain which lasted for three days. During this time she lost a certain amount of blood from the uterus and a substance supposed to have been a "mole" was passed per vaginam. She was confined to bed for four days and menstruation which had been regular up to the occurrence reappeared five weeks later.

On examination the uterus was found to be displaced to the right by a mass which bimanually gave fluctuation. The tumour was inseparable from the uterus and with the latter completely filled the pelvis. There were no signs of pregnancy and the sound passed into the uterus demonstrated that the cavity of the latter was of normal size. Provisionally I diagnosed cystic tumour and advised operation.

The abdomen was opened by separating the fibres of the left rectus muscle. The uterus was found occupying the pelvis on the right and a translucent cystic mass filling the remainder of the pelvic opening. This mass consisted of one large cyst and three smaller ones. On insinuating my hand behind the uterus I broke through some delicate membranous structures into a friable mass lying in the pouch of Douglas. This mass was separated and on bringing it into the light of day it was at once identified as dead placental tissue. A little further search was rewarded by finding a partially macerated fœtus. The mass had lain in Douglas's pouch, retained mechanically in position by the uterus and cyst filling the brim of the pelvis. The cystic tumour still remained. It was, as I have said, continuous with the uterus, the peritoneum passing from one to the other without leaving any space to tie off the tumour in the usual way. It was, however, possible, working through an opening in the peritoneum behind, to bring the finger into contact with the actual wall of the principal cyst and partially to enucleate it from the uterus and from the peritoneum of the broad ligament without interfering very much with the latter. The portions of the surrounding tissues which could not be separated in this manner were treated as pedicle and ligatured with silk. The removal of the principal cyst left the other cystic portions of the broad ligament and the remnant of the Fallopian tube easy to manipulate and tie off. The Fallopian tube could be traced from the uterus into an attenuated membrane which had obviously formed the fœtal cavity and which lay on the postero-inferior surface of the cyst mass. There was at first rather alarming oozing of blood into the ragged cavity from which the placenta and fœtus had been removed. In these circumstances a short time ago one would have felt inclined to insert a drain but of late the peritoneal cavity has been shown to possess such powers of absorption and recuperation if only it is completely closed that I determined to dispense with drainage. To stay hæmorrhage a swab secured on a long Spencer Wells forceps and soaked with adrenalin was held in the bleeding space while the peritoneal layer of the abdominal wall was being sutured. There was no further trouble from either hæmorrhage or absorption, the temperature remaining normal and the pulse-rate never exceeding 80.

The fœtus, in so far as its macerated condition allowed one to judge, appeared to have developed to about the fifth month. It is also of considerable interest to note the absence of amenorrhœa from conception to the date of rupture and the comparatively slight inconvenience caused by the latter event and by the presence of a dead fœtus and placenta in the abdominal cavity for nearly a year. The symptoms which eventually brought the patient under treatment were, I take it, produced by the enlarging cysts. Bland-Sutton, among others, mentions the coexistence of parovarian cyst and tubal pregnancy and it is easy to see how a causal relationship might exist between the two conditions.

CLINICAL SOCIETY OF LONDON.

A Case of Milky Ascites in which the Opalescence was not due to Fat.—Rhinoplastic Operation [illegible] of the Nose.—Primary Adrenal [illegible] A Case of Diabetes Mellitus with Xanthoma and Lipæmia. Annual Meeting.

A MEETING of this society was held on May 26th, Dr. FREDERICK TAYLOR, the President, being in the chair.

The PRESIDENT and Dr. J. FAWCETT communicated a case of Milky Ascites in which the Opalescence was not due to Fat. The patient, a man, aged 31 years, was admitted into Guy's Hospital on Oct. 6th, 1904, and died a month later. His illness commenced in May, 1904, with œdema of the legs and face, followed by ascites, for the relief of which paracentesis was performed in all nine times. The fluid removed was always milky and this appearance was at first thought to be due to fat but under the microscope no fat globules, but only granules, were visible. On admission the urine was found to contain about 14 parts per 1000 of albumin and casts were present. No other signs of disease, with the exception of the ascites and nephritis, were found. At the necropsy there was milky fluid in both pleuræ and a large amount in the peritoneal cavity. The kidneys exhibited the typical aspect of a tubal nephritis. The other viscera appeared healthy. The pancreas weighed only 60 grammes but microscopically its structure was normal. Clinical examination of the ascitic fluid by Mr. J. H. Ryffel gave the following result: fat, 0·045 per cent.; proteid, 0·396 per cent.; iodine, 0·0966 per cent. (probably as potassium iodide); and chlorine, 0·264 per cent. as chloride. Mr. R. W. Allen reported that no fat globules could be detected under the microscope or extracted with ether; on precipitation with ammonium sulphate the fluid became quite clear. The analysis and microscopic examination showed that the milky appearance was not due to fat but probably to proteid in some form. The amount of fat present was only 0·045 per cent. Lactescent serous effusions in which the opacity was thought to be due to a proteid had been ascribed to (1) lecithin, (2) mucoid substances, and (3) to a proteid resembling casein. Lecithin seemed to be an important element in these effusions. Joachim and von Beinert in some recent researches pointed out that albuminous bodies of the globulin group might have had their solubility lessened by chemical combination with lecithin or by molecular arrangement, their conclusion being that the milkiness was probably due to a combination of lecithin and a proteid. Attention was also drawn to the association of lactescent serum and the presence of nephritis, as previously noted by Bright, Castaigne, and others.

Mr. JAMES BERRY read a paper on Rhinoplastic Operation for Syphilitic Destruction of the Nose. The patient, a man, aged 33 years, had acquired syphilis nine months before coming under observation and the whole of the left

---

ala had sloughed away. Under iodide of potassium the ulceration of the nose had quickly healed, but a large hole was left exposing freely the interior of the nostril. The patient was at first fitted with an artificial aluminium ala which he wore for three months. At the operation a flap was made and doubled on itself so as to present a free edge of skin at the edge of the nostril. Deep and superficial sutures were used. The doubled-up flap ultimately formed a prominent new ala which completely covered up the gap in the side of the nose. The triangular raw surface left between the eyelid and the nose was then closed by transverse suturing aided by undercutting and by a deep tension stitch of stout fishing gut passed from the centre of the cheek to the middle of the nose, left in place for seven days. The patient was left with a prominent and fairly shapely ala with which he was much pleased and a nostril through which he could breathe freely. The resulting scar was a linear one placed in the furrow between the nose and

Dr. SIDNEY P. PHILLIPS and Mr. B. H. SPILSBURY communicated a case of Primary Adrenal Carcinoma. The patient, a married woman, aged 40 years, suffered from loss of appetite, nausea, and occasional vomiting for about ten months before she noticed that the abdomen was enlarging. She then took to bed and a month later, on Dec. 15th, 1904, she went into St. Mary's Hospital, under Dr. Phillips's care, on account of ascites, loss of flesh, and debility. After removal by a trocar of 386 ounces of clear yellow fluid from the abdomen the liver was found to be greatly
enlarged and with nodules of [illegible]
it. There were no pain, no [illegible]

[illegible] by Mr. Spilsbury
[illegible] in the peritoneal
[illegible] cinoma originat-
ing [illegible] cells were for the
most part arranged in single or in double rows around a central lumen. There was only a small amount of fibrous tissue between the rows of cells and in places the cells rested directly upon the endothelium of the capillary blood-vessels. The occasional existence of accessory suprarenal bodies in the viscera had been described by various observers. Schmorl in 1891 had been the first to record the discovery of such aberrant "rests" in the liver in four cases in which the adrenal glands were themselves quite normal. Obendorfer had described two other cases. Pepere, who
[illegible] the subject with great minuteness had

[illegible]
its clinical and pathological characters; both cases occurred in women, aged 40 years; in both there were great enlargement and nodulation of the liver with copious ascites but without jaundice, pain, or pyrexia; and both ran a very rapid and malignant course to a fatal issue. Clinically it was impossible to distinguish these cases from other forms of cancer of the liver, though in the latter ascites rarely occurred without jaundice.—Dr. F. PARKES WEBER asked whether there was any obvious alteration in the blood pressure in this case because the cells of the tumour resembled, and were probably derived from, cells of the cortex of the adrenal tissue.

Sir DYCE DUCKWORTH reported a case of Diabetes Mellitus complicated by Xanthoma, Lipæmia, and Fatty Necrosis of the Pancreas.

The annual meeting of the society was afterwards held to receive the annual reports of the council and treasurer and to elect the officers and members of council for the ensuing session. As the result of the scrutiny of the ballot the following gentlemen were declared duly elected:—*President:* Mr. H. H. Clutton. *Vice-Presidents:* Dr. F. de Havilland Hall, Dr. J. Kingston Fowler, Dr. William Ewart, Mr. H. T. Butlin, Mr. Clinton T. Dent, and Mr. John R. Lunn. *Treasurer:* Mr. G. H. Makins. *Council:* Dr. F. E. Batten, Dr. Harry Campbell, Dr. J. Walter Carr, Dr. W. S. Colman, Dr. Norman Dalton, Dr. E. W. Goodall, Dr. W. Pasteur, Dr. F. J. Smith, Dr. H. H. Tooth, Dr. Claude Wilson, Mr. F. W. Strugnell, Mr. Anthony A. Bowlby, Mr. Albert Carless, Sir Alfred Fripp, Mr. J. Ernest Lane, Mr. T. H. Kellock, Mr. B. G. A. Moynihan, Mr. T. H. Openshaw, Mr. A. H. Tubby, and Mr. H. F. Waterhouse. *Honorary secretaries:* Mr. W. G. Spencer and Dr. Archibald E. Garrod.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on May 5th, Professor E. H. BENNETT being in the chair.

Professor BENNETT presented a note on Fracture of the Cartilage of the First Rib, illustrated by the exhibition of some six specimens of the injury. In a majority of the cases the individuals were females not likely to have been during life engaged in very heavy labour, such as might be assumed to cause new or false joints in the cartilage, and the recent fractures corresponded in all pathological details with fractures of the cartilages lower down in the chest.

Dr. T. G. MOORHEAD exhibited a case of Anomaly of the Mitral Valve. On the ventricular aspect of the large anterior cusp a small foramen with smooth edges was present which led into a sac about one-third of an inch in diameter.

Dr. R. ATKINSON STONEY showed a specimen of Tuberculous Disease of the Cæcum, Appendix, and Ileum, removed by operation from a female 23 years of age. At the operation a thickened band was found round the ileum one and a half inches from the cæcum. The cæcum itself was large, nodular, and thickened. The diseased parts were removed and a lateral anastomosis was performed. On opening the specimen a stricture with a diameter of half an inch was found in the ileum, the cavity of the cæcum was almost obliterated, and a second stricture was found in the commencement of the colon, with a diameter of a third of an inch.

Dr. W. J. THOMPSON showed a specimen of Recrudescent Ulceration of the Stomach. It was taken post mortem from a man, aged 29 years, who was admitted to Jervis-street Hospital, Dublin, on Feb. 21st. He had contracted syphilis five years ago and for the last two or three years had been drinking heavily. Physical examination showed the heart to be enlarged and organically diseased; there were also enlarged liver, dilated stomach, peripheral neuritis, and albuminuria. At the post-mortem examination the stomach was found to be enlarged, with a well-marked contraction near the pylorus.
[illegible] ulcers (two as large as a

form of malignant [illegible] parent. At birth it was of the size of a split pea, situated in the centre of the left upper eyelid. It was darkish in colour and somewhat

resembled a hæmatoma. It changed little for a week and then grew rapidly. It was lobulated, very elastic in feel, and had entirely lost its dark look and more resembled a cyst in feel and appearance. Three weeks afterwards recurrence took place in the neighbourhood of the wound; also over the malar bone and in the orbit. A second operation failed to eradicate it and a sub-maxillary gland became enlarged as well as one in the axilla. The orbital tumour was, after three months, of the size of a small potato and similar in character to the original growth removed. As far as could be ascertained this case was the only one of congenital sarcoma of the eyelid which had been recorded.

SECTION OF SURGERY.

Cleft Palate.—Volvulus of the Cæcum.—Exhibition of Cases and Specimens.

A MEETING of this section was held on May 12th, Mr. THOMAS E. GORDON being in the chair.

Sir THORNLEY STOKER read a paper on the Operation for Closure of the Hard Palate during the three months following birth, practised by Mr. Brophy of Chicago. He (Sir Thornley Stoker) said that he had performed it in three cases and found it very successful. This operation could only be practised during the period mentioned, as the bones were afterwards too fully ossified to permit the necessary change in their position. It consisted essentially in drawing the maxillæ and palate bones of opposite sides together so as to close the cleft. This was done by two wire sutures passed across from one side to the other above the alveolar processes. They lay above the floor of the nasal fossæ. One was inserted behind the malar ridge, the other in front of it. The bones were forced together by pressure so as to close the cleft, the edges of which had been pared. If the bones could not be approximated by pressure alone the malar process was divided on each side. The anterior and posterior ends of the wires on each side were twisted together over a lead suture-plate fitted to the outer surface of the alveolus. The hard palate, the premaxillæ, and generally the soft palate were operated on at once. The hare-lip was closed subsequently when free access to the mouth for operative purposes was not required. The wire sutures were withdrawn after about four weeks.—Mr. GORDON said that in his opinion the risks of Brophy's operation were somewhat serious, especially in those cases where it was found at first impossible to bring the edges of the palate together.—Mr. W. S. HAUGHTON said that he had performed an operation very similar to Brophy's on a child nine days old. The parts were easily brought together and there was an entire absence of shock.

Mr. J. F. L. KEEGAN read notes on a case of Volvulus of the Cæcum and exhibited the specimen.—Mr. Kennedy and Mr. E. H. Taylor discussed the communication.

Mr. KEEGAN also exhibited a patient after a wiring operation for Fractured Patella.

Major M. P. HOLT, R.A.M.C., exhibited an Aneurysm of the Innominate Artery which had been successfully treated by ligature, the patient dying from tuberculosis 15 months later. He also exhibited an aneurysm of the innominate artery in which an unsuccessful result followed distal ligature and wiring by Power and Colt's apparatus.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Leeds on May 26th, Dr. J. Lloyd Roberts, the President, being in the chair.—Dr. E. O. Croft (Leeds) showed a Myoma of the Vaginal Wall nearly two inches in diameter, which occupied a lateral position and extended to within half an inch of the urethra. It produced no symptoms beyond slight bleeding from an excoriation on its most prominent portion. The nature of the growth was demonstrated by microscopic sections. Amongst 54 vaginal growths there were only three of this nature. They were always single, generally occupied the middle line, and were usually sessile. They were derived from the muscular tissue of the vaginal wall itself.—Dr. C. Oldfield (Leeds) described the case of a female, aged 22 years, from whom he removed a Hydatid Mole, discovering at the same time the presence of Bilateral Ovarian Cysts. Five weeks after the removal of the mole the abdomen was opened and the two multilocular ovarian cysts were removed. The uterus was three times the normal size and was very soft in texture. It was therefore removed by supravaginal hysterectomy. The cysts were found to contain in their walls a large amount of lutein tissue and examination of the uterus revealed the presence of a chorio-epitheliomatous growth in the posterior wall. The presence of malignant disease being thus established the cervix was removed a week later. Dr. Oldfield explained the observed relationship between the presence of excessive lutein tissue in the ovaries (with or without definite cyst formation) and the occurrence of vesicular degeneration of the chorion. Fraenkel had concluded that one of the functions of the corpus luteum was to preside over the embedding of the ovum in the uterus. The presence of excess of lutein tissue appeared to determine excessive growth of the trophoblast—the essential feature of vesicular mole formation. From this it was only a short step to the production of chorio-epithelioma. If the association between excess of lutein tissue and trophoblastic overgrowth could be proved by further investigation an important contribution would have been made to the pathology of malignant disease.—Dr. A. Stookes (Liverpool) and Dr. S. Buckley (Manchester) described cases of Pseudo-hermaphroditism and Dr. G. W. FitzGerald (Manchester) read a paper on Ruptures of the Vagina in Connexion with Parturition.

Reviews and Notices of Books.

The Principles of Heredity with some Applications. By G. ARCHDALL REID, M.B. Edin., F.R.S. Edin. London: Chapman and Hall. 1905. Pp. 359. Price 12*s.* 6*d.* net.

IN this work the author does not, as the title might imply, confine himself to the subject of heredity pure and simple but sets himself the ambitious task of unfolding a complete scheme of biological evolution. It is now considered by most biologists that in the case of all the higher animal organisms the reproductive cells are merely housed within the soma and that no acquisitions made by the latter—no somatic *modifications* as they are termed—are capable of so influencing the reproductive cells as to be transmissible to the offspring. New characters, however, which arise from peculiarities in the constitution of the reproductive cells, or, as they are termed, natural *variations*, are transmissible, and it is on such that natural selection operates. Dr. Reid advances from the field of pathology convincing arguments against the inheritability of somatic acquisitions. Were these transmissible every impress made on the soma, whether by trauma or disease, would tend to appear in the offspring whose tissues would in the course of a few generations become so disorganised that the species would necessarily become extinct. Not only does this not occur but species which are subjected to injurious agencies, such as the parasites of malaria and tuberculosis, far from degenerating, tend actually to undergo evolution against them. Again, if somatic acquirements be transmissible, why, asks Dr. Reid, is acquired immunity not inherited? and how comes it that the European has not by this time attained to racial immunity against such diseases as measles and whooping-cough?

One of the most important problems presented to the biologist is the origin of natural variations. That biparental reproduction gives rise to them is admitted by all and Weismann has long contended that the essential purpose of this mode of reproduction is to provide variations on which natural selection may operate. However this may be, it is now known that such variations may also arise in parthenogenetic organisms, and Dr. Reid further insists that the variations which result from biparental reproduction are not progressive but regressive—reversions, in fact, towards an ancestral type in which no *additional* characters capable of being accumulated by natural selection appear. It is well known that when two varieties of a species are crossed the most recently evolved characters tend to be eliminated from the offspring; and Dr. Reid contends that the essential object of biparental reproduction is to bring about this very regression and in this way to rid the species of useless or injurious characters. When it became known that somatic variations were incapable of inheritance it was obviously impossible to account for the disappearance of useless parts through the *inheritance of disuse acquirements; while it* seemed impossible to account for their disappearance by the action of "reverse selection" alone. Dr. Reid admits that the latter may, to some extent, hasten the elimination of burdensome and injurious characters and cause the atrophy *of an organ in the later stages of development,* such as the eyes of cave-dwelling animals (in which case, however, there is a prolongation rather than an abbreviation of ontogeny), but he insists that it is altogether incompetent to get rid of the numerous useless and injurious characters which during the long phylogeny of species are continually demanding elimination. For this purpose biparental reproduction is required: all that is needful is for natural selection to cease to operate in regard to any character and that character is automatically "planed away." "When natural selection is stringent it overcomes the tendency to regression and progressive evolution ensues. When it is less stringent it merely maintains the structure. When it is still less stringent, and even more when it is has been completely abolished, the tendency to reversion comes into play and causes regressive evolution." Nothing in nature is more certain "than that the function of biparental reproduction is to produce regressive variation; and nothing in science is more remarkable than that in spite of plain, abundant, and conclusive evidence it should so long have been regarded as the cause of progressive variations. .. ... This, then, is the unknown factor in evolution. Not one but two forces are continually at work in nature—Natural Selection and Reversion. The former causes progressive evolution; the latter regressive evolution. They are opposed but one would be quite inadequate without the other." Dr. Reid holds that cross-breeding benefits by causing an elimination of the useless and injurious characters which are apt to result from too close in-breeding.

So much for biparental reproduction as a cause of variations. How far may they result from the direct action of the environment on the reproductive cells? While granting that these cells, like all others, are capable of being profoundly affected by their environment, the author contends that their hereditary tendencies are little, if at all, influenced in this way. Natural selection, he believes, has brought about *an all but absolute insusceptibility of the germ plasm—so far* as its developmental tendencies are concerned—to the influence of the environment. How, on any other supposition, would it be possible for a species long to maintain its identity? and, how would it be possible, considering how frequently the reproductive cells are bathed in unhealthy plasma, for the offspring not always to be affected injuriously? It is true that unicellular organisms may be made to undergo considerable modification by cultivating them in special media, thus suggesting that their hereditary powers may in this way be changed, but the author reminds us that their enormous rate of increase allows rapid modification by means of natural selection. Again, the action of the environment on the germ cells cannot account for the great variety of progressive variations which may be observed among the individuals of the same litter, seeing that in such cases the germs and sperms respectively have from their first coming into being been subjected to practically the same environment.

Dr. Reid, thus finding neither biparental reproduction no the direct action of the environment on the germ plasm *competent to account for progressive variations,* concludes that they must arise spontaneously; that natural selection has endowed the germ plasm with a highly advantageous tendency to vary within certain narrow limits with the object of producing natural variations on which natural selection may operate, just as, on the other hand, it has rendered the germ plasm highly resistant to environmental influences.

Ontogeny takes place by recapitulation; the individual *tends to recapitulate the ontogeny of the parents,* these, again, that of their parents, and so on to the beginning of life. Hence ontogeny is to some extent an epitome of phylogeny, or the life-history of the race. But it is never an exact recapitulation. Man, for example, does not in his ontogeny *exactly recapitulate that of his piscian prototype.* The ontogeny unfolds the life-history of the species from its unicellular ancestor but "it is a history with great inaccuracies; with vast omissions and some additions, both omissions and additions being greatest in the earlier stages"; and some biologists by this "unlikeness of the embryo during the different stages of its development to the lower animals which were its prototypes in the life-history have declared that the development of the individual is not a recapitulation of the life-history of the race." But as Dr. Reid pointedly observes, *natural selection is at work during every phase of ontogeny,* on variations which manifest themselves not only in the adult but also in the embryo and fœtus, and is therefore capable of influencing each and every phase of ontogeny in correspondence with the requirements of the environment. "Step by step the race in all its developmental stages follows the change in the environment. To-day, for example, mammals retain their young within their bodies for prolonged periods. The whole structure of the embryo has altered in consequence. Thus the gills have almost entirely disappeared and a placenta has undertaken their function."

The author applies the principle of natural selection in explaining the evolution of species against disease. Evolution, he insists, takes place only under adverse conditions. "Every species undergoes progressive evolution under adverse conditions ... .. every species undergoes regressive evolution—i.e., degeneration—under beneficial conditions." Thus if a community is exposed to injurious agencies, such as the parasites of malaria or tubercle; or poisons, such as alcohol and opium, natural selection comes into operation and tends to start an *evolution against them.* In this way certain sections of mankind are evolving against tuberculosis and malaria, so that we find the West African far more resistant to malaria than the European and the latter more resistant to tuberculosis than the former. Thus, again, the Jews, from their long acquaintance with alcohol, have evolved into a sober race, while the Chinese have become temperate in regard to opium. Similarly town-bred communities tend to undergo evolution against the injurious conditions of town life, Dr. Reid stoutly contesting the prevalent view that, unless fresh blood be continually imported from the country, slum life leads in two or three generations to extinction. The resistance of the germ plasm to environmental conditions and the noninheritability of somatic acquirements negative such a supposition.

The marvellous power possessed by man of making acquirements—both mental and physical—is dwelt upon at considerable length. The purely instinct-led organism is held to a stereotyped environment by a stereotyped instinct, but as the complexity and instability of the environment increase instinct becomes *less and less adequate to adapt the* organism to it, and the ability to make adaptive acquirements becomes increasingly necessary, until (as in the case of man) it reaches well-nigh limitless proportions. It is pointed out that, with the exception of a few organic instincts, such as *hunger and thirst* and the sexual instinct, man's entire mental equipment is acquired and that many of his physical characters which we are wont to regard as inborn—the result of unaided developmental force—are essentially acquired. Not until this truth is recognised is it [illegible] greatly man can be influenced for good or ill by environmental agencies and how much may be done by education to rear a race of capable citizens. It is even contended that the mental differences of races depend more upon mental environment than inborn peculiarity. The influence of religion in moulding national character is cited in this connexion and it is argued that the followers of any great religious creed, such as Mahomedanism, show all the world over a remarkable mental likeness, no matter to which race they belong or what clime they inhabit. The author further maintains that the rise and fall of nations is not a mere matter of economic conditions, but is largely, nay chiefly, the outcome of national character as determined by mental environment. A great responsibility therefore rests upon us to train up our youth in the right way. Why, asks Dr. Reid, burden the young mind with things non-essential and ephemeral while allowing it to remain ignorant of the eternal realities of nature? Why fuddle it with the words and the relations between the words of a dead language—mere symbols—and allow it to learn nothing of the great scheme of evolution, of the inexorable laws of heredity, and the merciful mercilessness of natural selection? "The time has arrived when the subject of heredity must engage the attention of thinking people, especially medical men. A knowledge of it should be part of the ordinary professional equipment of the physician. ...... A great field of knowledge remains untilled. It is the task and duty of medical men to gather its harvests and apply them to the betterment of mankind. ...... Owing to the improvements in medical science and the consequent survival of the hitherto unfit, tremendous problems have arisen, the solution of which cannot long be delayed without disaster to the species."

In these words the author ends a work distinguished alike for incisiveness of diction, originality of thought, and cogency of argument. It is difficult to controvert any of the main conclusions and there is but little from which we can actively dissent. We are not convinced that the evolution of intelligence has reached its term, as Dr. Reid suggests. The most important of his deductions is that concerning the part which biparental reproduction is assumed to play in evolution. Should it stand the test of time Dr. Reid will have discovered a great biological law, one second only in importance to that of natural selection itself.

The subject of heredity is now exciting great interest not only in the medical profession but among the lay public who look to the profession for instruction in regard to it. Dr. Reid's work, therefore, appears at an opportune time and every medical man should study it carefully.

The Cambridge Natural History. Edited by S. F. HARMER, F.R.S., and A. E. SHIPLEY, F.R.S. Vol. VII., Ascidians, Fishes, &c. By Dr. HARMER, Professor HERDMAN, Professor BRIDGE, and M. BOULENGER. Royal 8vo, pp. xvii.-760. London: Macmillan. 1905. Price 17*s.* net.

THE bulk of this volume deals with fishes, but the earlier chapter devoted to those groups—the Ascidians, Balanoglossus, Amphioxus, and some other types lying at varying distances from the borderland of the vertebrate sub-kingdom —is by no means to be neglected. The fact is, however, that the last-mentioned creatures do not lend themselves altogether to "popular" exposition. Important though they are and really mysterious of their kind—for the exact relationship of tunicate and hemichordate generally to the undoubted vertebrate may be that of the ancestor or the degraded descendant—the importance is for the anatomist and embryologist, and those who seek for tit-bits of natural history will not find much refreshment in the accurate and rightly solid pages of the earlier portion of this volume. It appears to us, however, that the authors of the part relating to fishes might have relaxed a little and dropped into anecdote more freely. Particularly can this be said of M. Boulenger who is stern and uncompromising in his mode of dealing with the classification of the teleostean fishes and will have nothing to do with any matters of non-technical interest. The reader seeking, for example, information as to the flat fishes of our coasts is confronted with a long list of generic names in italics, which are for the most part names and nothing more. This section is, in fact, as we think, either too technical or not technical enough. It has the disadvantages of the catalogue without the advantages of a scientific treatise. There is some mystery, too, as to the scheme of classification of the teleostean fishes adopted by M. Boulenger. The author distinctly, though not immodestly, congratulates himself upon the far-seeing character of the scheme adopted by him. On the other hand, the editors remark that it is but common fairness to M. Boulenger to call the attention of the reader to the fact that his (M. Boulenger's) MS. was handed in in the year 1902. What does this mean? Has the lapse of time failed to justify M. Boulenger's anticipations or was he so extremely far-seeing that up to the present panting research has toiled after him in vain?

That Professor Bridge's account of fishes in general is largely technical was to be expected and is emphatically to be justified. He has provided us with precisely what is wanted—a good general account of the structure of this group. There is not, so far as we are aware, any so complete and luminous an account of fishes in existence. The sections which impressed themselves upon us as the best are those dealing with the brain and the respiratory system, especially the account of the accessory respiratory organs found in those fishes which are truly to be termed fishes out of water, which leave for variable periods their native flood. The Anabas scandens of the East and the toad-faced Periophthalmus, which hops along marine mud flats in search of wandering molluscs, are examples, which, with many others, are fully treated of by Professor Bridge. As a matter of patriotism it is gratifying to observe how frequently he has to quote the names of Englishmen who have contributed to, and advanced our knowledge of, this group of animals; and among them the name of Mr. Cunningham, the late superintendent of the Marine Biological Laboratory at Plymouth, naturally prevails on account of the vast amount both of technical and economic ichthyology which has been forwarded by his investigations. Nor is Professor Bridge himself backward as a student of the group which is dealt with by him in this work. And it is precisely for that reason that this as well as other volumes of the Cambridge Natural History are likely to have a large public: so much natural history is written by those only acquainted with books or who are of no authority in the subjects of which they treat.

Report on the Origin and Spread of Typhoid Fever in United States Military Camps during the Spanish War of 1898. By WALTER REED, Major and Surgeon United States Army; VICTOR C. VAUGHAN, Major and Division Surgeon United States Volunteers; and EDWARD O. SHAKESPEARE, Major and Brigade Surgeon, United States Volunteers. Vol. I., Prepared in accordance with the Act of Congress, under the direction of Surgeon-General ROBERT M. O'REILLY, United States Army. Washington: Government Printing Office. 1904. Pp. xviii. + 721. Vol. II., 96 Charts and Maps.

THE publication of the complete report of the board on the origin and spread of typhoid fever in the United States military camps during the Spanish War of 1898, by which this vast and valuable collection of data is made available for the profession at large, is greatly due to the interest and appreciation of Mr. Root, late Secretary of War, supplemented by the action of Congress. The letter of transmittal is signed by Major Vaughan, the only member of the board who lived to see the work finished. In this letter he pays a tribute to the work of his colleagues and acknowledges the valuable help rendered at great personal sacrifice by Dr. Christopher Childs of University College, London. The following are the most important statements and conclusions derived from the report.

During the war every regiment constituting the first, second, third, fourth, fifth, and seventh army corps developed typhoid fever. More than 90 per cent. of the volunteer regiments developed typhoid fever within eight weeks after going into camp. Typhoid fever developed also in certain of the regular regiments within from three to five weeks after going into camp. Typhoid fever became epidemic both in the small encampments of not more than one regiment and in the larger ones, consisting of one or more corps, and in camps located in the northern as well as in the southern states. Typhoid fever is so widely distributed in America that one or more cases are likely to appear in any regiment within eight weeks after assembly.

The miasmatic and pythogenic theories of the origin of typhoid fever are not supported by these investigations, which confirm the doctrine of the specific origin of typhoid fever. With typhoid fever as widely disseminated as it is in America the chances are that if a regiment of 1300 men should be assembled in any section and kept in a camp, the sanitary conditions of which were perfect, one or more cases of typhoid fever would develop. Typhoid fever is disseminated by the transference of the excretions of an infected individual to the alimentary canals of others. It is more likely to become epidemic in camps than in civil life because of the greater difficulty of disposing of the excretions from the human body. A man infected with typhoid fever may scatter the infection in every latrine in a regiment before the disease is recognised in himself.

Camp pollution was the greatest sin committed by the troops in 1898. In some instances the space allotted to the regiments was inadequate. Many commands were allowed to remain on one site too long. Requests for change in location made by the medical officers were not always granted. Greater authority should be given to medical officers in questions relating to the hygiene of camps. It may be stated in a general way that the number of cases of typhoid fever in the different camps varied with the methods of disposing of the excretions. The tub system of disposal of fæcal matter is to be condemned. The regulation pit system is not a satisfactory method of disposing of fæcal matter in permanent camps. In permanent camps where water carriage cannot be secured all fæcal matter should be disinfected and then carted away from the camp. Infected water was not an important factor in the spread of typhoid fever in the national encampments in 1898. To guard against the contamination of the water-supply troops in the field should be provided with means for the sterilisation of water. Flies undoubtedly served as carriers of the infection. It is more than likely that men transported infected material on their persons or in their clothing and thus disseminated the disease.

Typhoid fever as it developed in the regimental organisations was characterised by a series of company epidemics, each one having more or less perfectly its own individual characteristics. It is probable that the infection was disseminated to some extent through the air in the form of dust. When a command badly infected with typhoid changes its location it carries the specific agent of the disease in the bodies of the men, in their clothing, bedding, and tentage. After a command becomes badly infected change of location, together with thorough disinfection of all clothing, bedding, and tentage, is necessary. Except in the case of the most urgent military necessity one command should not be located upon the site recently vacated by another. The fact that a command expects to change its location does not justify neglect of proper policing of the ground occupied. It is desirable that the soldier's bed should be raised from the ground. In some of the encampments the tents were too crowded. Medical officers should insist upon soldiers removing their outer clothing at night when the exigencies of the situation permit.

In addition to the recognised cases of typhoid fever there were many short or abortive attacks of this disease which were generally diagnosed as some form of malarial fever. About one-fifth of the soldiers in the national encampments in the United States in 1898 developed typhoid fever Army surgeons correctly diagnosed about half the cases of typhoid fever. The percentage of death among cases of typhoid fever was 7·61. When a command is thoroughly saturated with typhoid fever it is probable that from one-fourth to one-third of the men will be found susceptible to this disease. In military practice typhoid fever is often apparently an intermittent disease. The belief that errors in diet with consequent gastric and intestinal catarrh induce typhoid fever is not supported by the investigations. More than 90 per cent. of the men who developed typhoid fever had no preceding intestinal disorder. The deaths from typhoid fever were 86·24 per cent. of the total deaths. The morbidity from typhoid fever per 1000 of mean strength was a little less than one-fifth. The mortality from typhoid fever per 1000 of mean strength was 14·63. The average period of incubation in typhoid fever is probably about ten and a half days.

The maps and charts in the second volume show graphically what has been stated in words in Vol. I. The object of displaying by charts the diseases prevalent in the different regiments is to show to the eye the distribution of diarrhœa, typhoid fever, so-called malarial fever lasting ten days and upwards, and so-called malarial fever lasting less than nine days, but especially of typhoid fever, not only in point of time, but also with reference to company outbreaks. A glance at the charts emphasises the fact that typhoid fever generally appeared as separate company outbreaks. This appears to the authors to be most convincing proof that the agent of infection, as a rule at least, was not present in either the food or the drink supplied to the regiment. Typhoid fever must have been spread largely by personal contact and by the contamination of tents, blankets, clothing, and the persons of individuals. This is also emphasised in the smaller maps introduced into the text of Vol. I., in which the tent distribution of the disease was demonstrated. The relation between typhoid fever, diarrhœal diseases, and the so-called malarias, both short and long, is graphically illustrated in many of the charts. The report is a most interesting one.

LIBRARY TABLE.

Notes on the Sorbonne.—We have received a small pamphlet, written by Mr. J. A. Randolph and published by Mr. Dennis Lane, of the Strand, London, W.C., entitled "The Sorbonne and its Secret Chapels." It gives an interesting account of the vicissitudes through which this famous establishment has passed during its lifetime of over 700 years, for it was founded in 1201. The founder was a pious villager from the diocese of Rheims, by name Robert de Sorbon, and he it was who, with the aid of St. Louis and the then Archbishop of Paris, founded a theological college for 16 poor students. By the fourteenth century this number had been increased to 36 and during the middle ages the doctors of the Sorbonne were acknowledged masters of theology. In the seventeenth century Richelieu offered to rebuild the college buildings and to provide a church if they would make him Provisor. This was in 1607 and 20 years later the building was begun. Certain of the funds were provided by money borrowed by

Richelieu from the doctors of the Sorbonne, so that his generosity is somewhat on a par with that of Henry VIII. in his dealing with St. Bartholomew's Hospital. The church was completed in 1653 and is remarkable for containing four small chapels in the thickness of the piers supporting the dome. After the Revolution, when the Sorbonne shared in the general *débâcle*, Napoleon reconstituted it and it is now a school for theology, science, and literature. New buildings have been erected but Richelieu's church still stands. So many British medical men have recently been enjoying the hospitality of their French brethren and have no doubt visited the new Sorbonne that we think it may be interesting to those of our readers who have not been to Paris to read this account of an ancient yet living French educational establishment.

In Confidence to Boys. By H. BISSEKER, M.A., formerly a Public School House-Master. Revised by the Council of the Medical Officers of Schools Association. London: Adlard and Son. 1904. Pp. 32. Price 1*s.* net.—It is the conviction of most of those who have thought a good deal about the truest interests of boys that after a certain age every boy should have important physical facts placed before him as delicately as possible. This book, originally written for private circulation, was so warmly received that it is now issued for a wider circle of readers. It has been revised by the council of the Medical Officers of Schools Association, a circumstance which adds greatly to its value and gives it authority. We have read the little book carefully and we feel that if it be read by boys with care and thoughtfulness it must be both a messenger of good and a means of help and encouragement. The book may safely be placed in a boy's hands and we wish it a very extensive circulation.

Thomas Carlyle: The Man and his Influence. By PERCY WARNER. London: Chapman and Hall. 1904. Pp. 66. Price 1*s.* net.—This essay was written for a local literary society. The author's excuse for publishing it is the hope that it may induce those who would know and judge Carlyle, "to do so by the light of all that is essentially great and good in his life and character, and to seek him—where only he can be truly found—in his works." It is a pleasant little book but it contains, of course, no new information, if we except a letter to Fraser, his publisher, on the occasion of the calamity of the destruction of the first volume of his great work on the "French Revolution." This letter shows how Carlyle, querulous and irritable as he too often was in the smaller affairs of life, could meet a great misfortune. The author avoids controversy. He shows us Carlyle in many moods and places, "ofttimes disturbed on the surface by trifling troubles, but never diverted from what he believed to be right and true." The book is written with discrimination and judgment and may be widely read with advantage.

The Effects of Tropical Light on White Men. By Major CHAS. E. WOODRUFF, A.M., M.D., Surgeon, United States Army. London and New York: Rebman, Limited. 1905. Pp. 358. Price 10*s.* 6*d.* net.—This is an interesting volume and will well repay the reader for the time spent in its perusal. The basis for all the arguments is that living forms are distributed in zones the boundaries of which are isothermals. A species is sharply limited in the northern and southern extensions and though it may be found over longer distances east and west it is never found out of its zone. Migration is followed by extinction sooner or later, for acclimatisation is not possible. The work had its origin in an attempt to prove or to disprove the theory, announced by von Schmaedel in a paper read before the Anthropological Society of Munich in 1895, that pigmentation of the skin in man was evolved for the purpose of excluding the dangerous actinic rays of light which destroy living protoplasm. It gave at once the reasons for the evolution of nigrescence and blondness, the reasons why Europeans have always failed to colonise in the tropics, and the reasons why blonds disappear when they migrate from their northern home. Man, evolved from one or more anthropoid types by the law of selection, gradually spread to new environments to which he became adjusted by the same law of the survival of the fittest variations. Hence arose a separate type in each zoological zone, and each type is unfitted for residence in any other zone markedly different from the ancestral one. In the section on the Disappearance of Blond Aryan Immigrants the author says: "Scarcely a work on the subject has clearly and definitely grasped the main reason—namely, that a civilisation dies because the people who built it up die out from climatic unfitness. All the ancient subtropical civilisations were built up by men who had migrated south of their zones, and the men perished chiefly because they possessed too little pigment for the tropical light to which they were subjected." It is latitude, modified by afforestation and cloudiness, which determines fitness as to pigmentation, though it is slightly modified by elevation. The author writes that the "evolution of blondness required a cold, dark, northern country—probably a cloudy, rainy, misty, forest country—the exact conditions needed for the evolution of the brain by natural selection and the exact conditions of the countries where we have placed the origin of the Aryan or Teuton." He dwells on the superiority of the blond over the brunette in many ways and on many questions and points out that the submissiveness to authority so characteristic of the dark races, the Mediterranean type and the Alpine or Asiatic type, is one reason for the evolution of that type of Christianity found in the Roman and Greek churches. This submissiveness is repugnant to the "free and contentious" blond Aryan; consequently the Baltic type of a man is a Protestant, as we see in Scandinavia, around the Baltic, in North Germany, Holland, Scotland, and Northern Ireland. The final chapter (XIII.), headed Practical Rules for White Men in the Tropics, is a valuable one and the contentions and recommendations are, on the whole, wise. Major Woodruff is opposed to any calisthenics and out-door sports which are indulged in for the sole purpose of increasing the musculature and recommends that athletic contests should be abolished in the tropics. The book is one specially for anthropologists but it will interest all those who are living in the tropics where it will be welcomed.

JOURNALS AND MAGAZINES.

Caledonian Medical Journal.—In the April number Dr. James Mackenzie of Burnley makes some suggestions for the observations of new paths in the spinal cord. He considers that the manner in which pain spreads often shows unmistakably that there must be paths in the spinal cord which are independent of segmentation. Dr. S. R. Macphail of Derby writes on the relations which formerly existed between the surgeons and the barbers in each of the three divisions of the United Kingdom. In London the barber surgeons and the surgeons proper were incorporated by Act of Parliament in 1540 and separated in 1745, when the Surgeons' Company was formed. In Dublin the barber surgeons and the surgeons were amalgamated in 1576 and separated in 1784, the Irish College of Surgeons being founded immediately. In Scotland the procedure was different. In 1505 the incorporation of barber surgeons of Edinburgh obtained from King James IV. of Scotland the foundation charter of the College of Surgeons of Edinburgh, which will in the month of July this year celebrate its quatercentenary. The separation between the Scottish surgeons and barbers was not abrupt or formal but came about gradually by the barber surgeons recognising that practising as barbers was unsuitable to the position as surgeons It is announced that the annual meeting of the Caledonian Medical Society will be held in Manchester on June 23rd

New Inventions.

THE TYPHOID AGGLUTOMETER

WE have received from Messrs Parke, Davis and Co a handy little apparatus for the performance of the Gruber-Widal test for typhoid fever without the use of a microscope It consists of four small tubes each containing a suspension of dead typhoid bacilli arranged side by side in a stand, three of these tubes are for inoculation with the serum to be investigated, the fourth being left as a control Apparatus is also supplied for collecting the blood, diluting the serum obtained from it, and for inoculating the tubes The method of procedure is as follows a few drops of blood are received into a short wide tube labeled "blood tube" and allowed to coagulate, the serum, which separates, is drawn up into a glass tube with a rubber bulb and two drops are then dropped into a tube containing fluid, labeled "serum diluting fluid" and well mixed Varying quantities of the serum thus diluted are dropped into the three typhoid suspensions so as to give dilutions of 1 in 30, 1 in 50, and 1 in 100 respectively These tubes are then corked and shaken to insure admixture and then placed in a warm room, an incubator not being necessary If a positive reaction results flocculi appear in one or more of the tubes, which must be carefully compared with the control In the course of a few hours these flocculi sink to form a distinct layer at the bottom of the tube We have tested the apparatus with the blood of a case of typhoid fever, which gave a well marked reaction with the 1 in 30 and 1 in 50 tubes within three hours and a slight precipitate in the 1 in 100 tube, a deposit being very distinct in all three 12 hours afterwards The apparatus was kept in an ordinary warm room and not in an incubator A control performed with the serum of the same case by means of the ordinary Widal test with the microscope gave a good agglutination with a dilution of 1 in 40 in about half an hour

The apparatus is supplied in a convenient form and is easy to use, the directions given with each apparatus being clear and explicit Each agglutometer serves for one test only It should be of use in general practice, especially where laboratory assistance is difficult to obtain, since the information afforded by the test appears to be as trustworthy as that afforded by the usual laboratory method It will be remembered that the original reaction as described by Gruber was a macroscopic method and that for some time past dead cultures have been used, especially in Germany where recently a considerable amount of work has been carried out with cultures treated with formaline and by means of Ficker's method, also presumably a method with dead cultures, although details of the preparation of his reagent are withheld by the author Some German authors[1] maintain that more uniformly trustworthy results are obtained by these means than by the ordinary method of employing living cultures and the microscopic study of the clumping process

AN ACCESSORY FOR FREEZING MICROTOMES

DURING the hot weather it is not easy to cut sections on the microtome by the freezing method whether with the ice well or ether spray microtome During the past few months I have used a simple device which makes one practically independent of the atmospheric temperature The illustration shows the device standing on the stage of an ether freezing microtome It is a box of thin metal, the walls of which are prolonged below the bottom of the box for the distance of a centimetre, the box is clothed in a jacket of felt When sections are to be cut a lump of ice of the size of the fist is slung in a towel, well beaten against the floor and the pounded ice is put into the box in alternate layers with common salt to fill the box By standing the ice chamber above the die on which the gum soaked block of tissue is placed the specimen is inclosed in an atmosphere below freezing point so that the cooling agent below the die rapidly freezes the block The saving in time is surprising whilst the diminished quantity of ether used in spraying is no small gain, not to mention the reduction of the wearisome labour of bellows blowing, also when using the ice chamber blocks of tissue of larger area and thickness can be frozen than is possible without its aid During the intervals of use the water should be poured out of the box occasionally, the ice rammed down to the bottom, and if the chamber be stood on a non conducting surface as a glass plate the freezing mixture will remain useful for an hour or more The ice chamber is made by Messrs J Swift and Sons of Tottenham Court road, W, its cost is small

FROM

THE LANCET, *SATURDAY*, June 2, 1827.

DISSECTION

To the Editor of THE LANCET

SIR,—Should any measure be brought before Parliament for the general improvement of our medical legislation, I would suggest that a clause be introduced to legalise the transfer of our corporeal frame by post obit, in the same way as any other property, and rendering it obligatory upon the executors, as survivors, to fulfil the bond

For myself, I have a great antipathy to being dissected by worms and would much rather my body was submitted to the scalpel of some elegant and scientific anatomist It is really astonishing to me Sir, that such prejudice should exist against dissection, and that people should be so anxious to be immured in a cold dark hole, there to become the prey of a set of loathsome zoophytes, how much more congenial it appears to have one's bones scraped beautifully clean, arranged after the order of Nature, and hung up in some chimney corner, or perchance honoured with a glass case! There would then be some pleasure in returning from the world of spirits to revisit our earthly tabernacle, and perhaps see some old friend again shake our bunch of phalanges and, like Hamlet, soliloquize over the sad remnants of mortality

Another advantage attending this method is, that when the trumpet sounds one will know where to find one's self, and instead of grubbing and squabbling for bones* in a church yard, be able to pack up and be off at a moment's notice!

I am, Sir, yours, &c
NON MEDICUS

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, MAY 24TH.

THE Council resumed, Dr. MACALISTER, the President, being in the chair.

The Case of Mr. P. H. Watson.

The Council considered the case of Percival Humble Watson, registered as of the Grand Hotel, Trafalgar-square, London, W.C., Mem. R. Coll. Surg. Eng. 1873, Lic. R. Coll. Phys. Lond. 1876, who had been summoned to appear before the Council to answer the following charge as formulated by the Council's solicitor:—

> That you abused your position as a medical man by committing adultery with a patient—namely, Mrs. Manford, a married woman, whom you had been and were attending professionally, of which adultery you were found guilty by decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice.

Mr. D. Macmillan, solicitor, appeared for the complainant, Dr. Manford, and Mr. F. Marshall, solicitor, for the defendant.

Mr. G. L. Lushington acted as legal assessor to the Council.

Mr. MACMILLAN, in presenting the case, said that Dr. Manford did not wish to act in any vindictive manner against Mr. Watson, but he thought that the facts of the case ought to be brought before the Council.

Dr. MANFORD went into the witness-box and, after swearing to the truth of his declaration, stated that Mr. Watson was his wife's regular adviser and that the decree of divorce was made absolute on Jan. 27th, 1905.

Cross-examined by Mr. MARSHALL: He had understood counsel to say during the divorce proceedings that they put in no defence.

Mr. MARSHALL declared that there was a defence, that counsel appeared, and that the defence was not withdrawn. Though the defence was not persisted in at the hearing it was not withdrawn.

Addressing the Council on behalf of his client,

Mr. MARSHALL said that Mr. Watson denied having abused his professional position or committed adultery with Mrs. Manford. No specific act of adultery was proved in the Divorce Court. Mr. Watson was now a ship's surgeon and had been compelled to leave on a voyage in April, that being the reason why he was not present. He contended that more required to be proved than the mere fact that a medical man had committed adultery with a lady who had been a patient. The decree was not evidence that adultery had been committed during professional relations. There was no evidence that adultery took place during the visits of the medical man. He added for the consideration of the Council that Mr. Watson was a man of 53 with a wife and daughter depending on him.

The Council having sat *in camerâ*,

The PRESIDENT intimated that the Council had determined that the facts alleged against Percival Humble Watson in the inquiry had been proved to the satisfaction of the Council and that they had judged him to be guilty of infamous conduct in a professional sense and had directed the Registrar to erase the name of Percival Humble Watson.

The Case of Mr. W. P. Kirwan.

The Council then proceeded with the consideration of the case of William Patrick Kirwan, registered as of 21, Danbury-street, Islington, N., Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882, who had been summoned to appear before the Council to answer the following charges as formulated by the Council's solicitor:—

> 1. That you have associated yourself with a medical aid association—namely, a firm of chemists trading at various addresses as the Acme Medical Hall and Pharmacy—which association has systematically, by means o [illegible] ds, labels, and notices, printed and painted, [illegible], name, and qualifications, and thereby canvassed [illegible] persons in the employ of the Acme [illegible] ctise medicine and to treat patients [illegible]

Dr. A. G. Bateman, secretary, and Mr. Hempson, solicitor of the Medical Defence Union, appeared as complainants.

The defendant appeared on his own behalf.

Dr. BATEMAN, in presenting the case, said that in October last attention was called by several medical men living in Islington and one of His Majesty's coroners to the fact that certain circulars advertising Mr. Kirwan had been issued. Information was also laid before the Medical Defence Union that visiting cards with Mr. Kirwan's address and hours of consultation had been placed in the doorway of a great many houses. Dr. Bateman directed particular attention to a circular from Messrs. H. Forewell and Co. stating that they had entered into an agreement with Mr. Kirwan and giving the hours of consultation. He also alluded to the signs over the defendant's premises and the serving of medicine by unqualified employés and contended that there had been advertising.

A clerk, named T. W. TYRRELL, who procured medicine from the defendant's assistants, gave evidence, in which he said his impression was that the three establishments which he visited at Danbury-street, Islington, Silver-street, Notting-hill-gate, and Fulham Palace-road were run by a company. They were ordinary chemists' shops. Not until he came near them did he see Mr. Kirwan's name.

The DEFENDANT, in stating his defence, said that after practising for a long time in the West of Ireland he came to London in October with a small capital and purchased the lease of the place in Danbury-street. That place had been carried on as an open surgery for 40 years. After 23 years' residence in the West of Ireland he had no idea that he could not keep an open surgery. Having to go to Ireland to bring over his family he received a letter while there from the Medical Defence Union and he immediately wrote to Mr. Forewell, who was a chemist, to destroy at once the circulars that had his name on them. Mr. Forewell had *carte blanche*, and he had put up a placard which had since been removed. He had also sent out circulars, but the moment he (the defendant) heard that that was objectionable they were destroyed. No cards or anything else of that description had been sent out for months, and he would be only too happy to carry out any instructions of the General Medical Council. He had never authorised his dispensers to practise medicine in any shape or form and they had not done so.

In their evidence the two dispensers, Mr. G. R. CARPENTER and Mr. E. PEARCE, denied that they had attempted to act as medical men.

The DEFENDANT then went into the witness box and stated that he had given strict instructions to his men not to sell poisons. The circulars relating to Forewell and Company, chemists, had been done away with; they were issued while he was in Ireland and he had them stopped when he was there. He never saw the circulars till he returned from Ireland.

The Council considered their judgment *in camerâ*.

The PRESIDENT announced that the Council had resolved that the facts alleged against William Patrick Kirwan had been proved to the satisfaction of the Council. The Council had also resolved that the further consideration of the charge against him should be adjourned to the next session in November. He would then have to appear before the Council and its judgment on the case would depend on the information it could have with regard to the conduct of his practice during the interval. He would have observed from the facts alleged against him what were the matters to which his attention must be most carefully given, relating to advertising, canvassing, and unqualified persons acting for him. The Council would have to be assured on those points in November.

The Council then adjourned till the following day.

THURSDAY, MAY 25TH.

The Council resumed, Dr. MacAlister, the President, being in the chair.

The Case of Dr. A. C. M'Arthur.

The Council considered *in camerâ* the case of Alexander Christie M'Arthur, registered as of Grafton, Clarence River, New South Wales, M.B., Mast. Surg., 1892, Univ. Glasg.

After consideration the PRESIDENT announced that the defendant had been summoned to appear before the Council to answer the charge that he abused his position as a medical man by eloping with a patient, a married woman, whom he had been, and was at the time, attending professionally. With regard to the charge the Council had resolved that the facts alleged against Alexander Christie M'Arthur had been proved to the satisfaction of the Council. The Council had also decided to judge Alexander Christie M'Arthur to be guilty of infamous conduct in a professional respect and had directed the Registrar to erase from the Register the name of Alexander Christie M'Arthur.

The Case of Mr. William Jones.

The Council then considered the case of William Jones, in regard to whom the Dental Committee had found that the following facts were established by the evidence;—

racti-
over

)hlets
"The
1904;
ipine,
ed by
said

Mr. HUGO YOUNG, K.C., appeared before the Council for the defendant and Mr. R. W. TURNER for the complainants, the British Dental Association.

The PRESIDENT intimated that as the case had been heard by the Dental Committee the question before the Council was the judgment on the facts.

Mr. HUGO YOUNG pointed out that the facts as found by the committee were a very short summary of the evidence brought before that committee.

The PRESIDENT remarked that it was out of order to go into the facts again.

Mr. HUGO YOUNG said he wished to observe that Mr. Jones had undertaken not to do any of those things which the committee referred to. The extreme measure of striking Mr. Jones off the list of registered dentists would be a somewhat unnecessary and hard punishment of what he had done. He had inadvertently published advertisements which had been found to be of an objectionable character. He had done nothing maliciously and did not desire to set himself up in defiance to the wishes of the Council. Although the committee had found those advertisements to be objectionable they might be characterised chiefly as advertisements objectionable because wanting in good taste as distinguished from advertisements that were, within the meaning of the Act of Parliament, disgraceful or infamous. For a mere error of judgment or taste, he submitted, some correction less than actual striking off the register would meet the justice of the case.

Mr. TURNER said they had here on the Register a person who desired to be at the same time a tradesman and a professional man. If the Council adjourned the case for six months it must be done in such a way as to show Mr. Jones and others that the Council did not recognise in any shape or form what some people called the right to advertise.

After the Council had considered its judgment *in camerâ*,

The PRESIDENT said the decision was that, on the facts found in the report of the Dental Committee, it had been proved that William Jones had been guilty of conduct which
had ɔfessional respect,
and to erase from the
Regı

Visitation and Inspection of Qualifying Examinations.

On the resumption of the discussion on the revised standing orders relating to the visitation and inspection of qualifying examinations Dr. MCVAIL moved that they be remitted to the Executive Committee for further consideration and that the committee should consult counsel as to the agreement of the proposed standing orders with Section 3 of the Medical Act of 1886. He said there were points which members did not understand and it would save time if the regulations were remitted.

Mr. YOUNG seconded the motion.

Sir VICTOR HORSLEY asked whether a special meeting of the Executive Committee might not be summoned for the following day.

The PRESIDENT said he did not think the committee regarded the matter as being so urgent as to require them to press counsel for an immediate opinion. As there should be no doubt remaining in the minds of members regarding the regulations he thought the committee would have no objection to the step suggested.

Dr. McVail's motion was then agreed to.

Qualification for Public Health Diploma.

Dr. BRUCE submitted the report of the Public Health Committee which was received and entered on the minutes. He moved the adoption of a recommendation that a note should be added to Rule 3 in the resolutions and rules adopted by the General Medical Council for diplomas in public health to the following effect:—

> *Note* (3).—A candidate who shall have produced evidence that he has himself held for a period of not less than three years an appointment as medical officer of health of a sanitary district having a population of not less than 15,000 may be exempted from the requirement of Rule 3.

The committee in its reference to this matter expressed the opinion that a note containing a similar exemption was dropped out of the existing regulations by inadvertence. The committee thought it desirable that a note conferring
should be re-introduced. The experience of
stration which it was the purpose of Rule 3
l be adequately secured in the case of a can-
himself for a sufficient time and in a district
ent been the responsible officer of health. In
view, however, of ions of public
health administra it desirable
that the period of the sanitary
district should now be more exactly defined than in the note above referred to Dr. Bruce said the Council had to consider whether the candidate should be required to hold the appointment for a certain number of years and what limit of population should be fixed. The meaning of the note was that a man who held an appointment for three years in a district the population of which was 15,000 would be freed from what he might call a second apprenticeship.

Dr. LINDSAY STEVEN seconded the motion for approval of the note.

The PRESIDENT said he thought the Public Health Committee had decided wisely. If the Council agreed that such a note should be inserted its general character and application to all cases would avoid the necessity for applications to the Council for exemption.

Sir JOHN WILLIAM MOORE thought the population limit seemed rather low. To reduce it to 15,000 was to open the door a little too widely.

Dr. BRUCE said the committee considered 15,000 the proper number as being a fair medium.

Dr. LINDSAY STEVEN said it had been pointed out by Mr. Power that if the number were raised to 20,000 they would not be granting any very great privilege because advantage of the rule could not be taken by a great number of men. On the other hand, if they reduced the number to 10,000 they would make it rather easy.

Mr. BROWN was of opinion that in mining villages and other small places the duties of medical officers were often more onerous than those of medical officers in large towns and consideration ought to be had for such men.

Dr. MCVAIL thought that the proposal of the committee was a great relaxation and ought to be limited to a period of
ad not studied the
than what he got
of little use as an
years. By this note he
ouraging public bodies to
ublic health.
misapprehended to some
e Council did not need to
obtained from the effect
of this note would be anything less than the educational value of Rule 3 without the note. He did not believe in the operation of a time limit in matters of this kind. The effect of leaving out the note would not be to encourage the local authorities to appoint holders of diplomas in public health. If they found that candidates for these posts had not diplomas and could not easily get them they would still appoint men without them and the action of the Council in the matter would be left out of account.

Sir John Batty Tuke said that he had given up the public health diploma in despair. They had whittled it down and watered it down year after year.

Dr. McVail moved as an amendment that the proposed note should cease to be of effect five years from this date. He said he was astonished that the President should advocate in regard to public health what was equivalent to unqualified practice.

The President said that he must disclaim any such interpretation of his remarks.

Dr. McVail said it was as it appeared to him.

Sir John Batty Tuke seconded the amendment.

Mr. Morris wished to know whether there would be accommodation in hospitals and elsewhere for the candidates to qualify for admission to the examinations that at present existed.

Sir John W. Moore pointed out that this was no new regulation at all. It was a note that had fallen out inadvertently.

The President, in the course of further remarks, said that they were tightening up Rule 3 and not lightening it.

Dr. Bruce said that with the limits of 15,000 of a population and three years of service it was quite safe to carry his motion.

Dr. Little expressed the opinion that the number of population should be reduced to 10,000.

On a division Dr. McVail's amendment was rejected by 17 votes against three. Ten members did not vote and three were absent.

Sir William Thomson moved as an amendment after the word "district" to insert "within the British Dominions and."

This was seconded by Mr. Jackson and agreed to.

Dr. Bruce's motion was then carried and the note as amended approved.

The Case of Mr. Herbert Du Cane.

The Council considered the case of Herbert Du Cane, registered as of 56, Bolton-road, Darwen, Lancs., Lic. Soc. Apoth. Lond., 1890, who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor:—

> That you abused your position as a medical man by committing adultery with a patient—namely, Mrs. Taylor, a married woman, whom you had been and were attending professionally.

Mr. Danckwerts, K.C., and Mr. Ellis Griffith appeared for the defendant, and Mr. F. G. Hindle, solicitor, for the complainants (the Darwen Medical Society).

Mr. Hindle opened the case for the complainants. He read a letter of confession written by Mr. Du Cane to Mr. Taylor and a declaration by Mr. Taylor regarding the regular professional attendance of Mr. Du Cane upon his family. A declaration was also read by Mr. William Standing, a chemist, who made up a prescription of Mr. Du Cane's for Mr. Taylor in January, 1904, as well as a declaration by a domestic servant regarding the dates of Mr. Du Cane's attendance. He contended that the defendant was in regular attendance on Mrs. Taylor, Mr. Taylor, and their child up to the very time of the elopement and mentioned that a decree nisi was obtained by Mr. Taylor on Nov. 25th last.

Mr. Taylor gave evidence in support of his declaration, stating that Mr. Du Cane was in regular attendance on his wife.

Mr. Danckwerts, addressing the Council on behalf of Mr. Du Cane, said that the defendant and Mrs. Taylor were both in Australia. He submitted that no evidence had been placed before the Council to prove that Mr. Du Cane used his professional position to steal the affections of Mrs. Taylor. The whole case hung upon Mr. Taylor's recollection and he asked the Council to give Mr. Du Cane the benefit of the doubt.

The Council having sat *in camerâ*,

The President announced that the Council had decided that the facts alleged against Herbert Du Cane in the notice of inquiry had been proved to the satisfaction of the Council and the Council had judged him to be guilty of infamous conduct in a professional respect and had directed the Registrar to erase from the Medical Register the name of Herbert Du Cane.

The Council then adjourned.

Friday, May 26th.

The Council resumed, the President (Dr. MacAlister) being in the chair.

Diplomas in Public Health.

Dr. Bruce moved the approval of a recommendation by the Public Health Committee to the effect that under Rule 3 relating to diplomas in public health candidates might produce evidence that they had been diligently engaged in acquiring a practical knowledge of the duties of public health administration under supervision of —— "outside the United Kingdom, a medical officer of health of a sanitary district having a population of not less than 30,000, who himself holds a registrable diploma in public health." He said it was right that the civil medical man should have the same privilege as medical officers in the army service. In proposing this amendment of the rules they were not in any way relaxing them but simply defining them. In his view they ought not to relax or in any way decrease the value of the diploma. He would be the last man to depreciate the diploma and he would be very glad if more men held it. He submitted a table showing that in the ten years ending 1904 the registrations of public health diplomas in England numbered 339, in Scotland 248, and in Ireland 83. He did not think that the remark levelled at them by Sir John Tuke was justified. They had not been on the downward grade.

Sir John W. Moore, in seconding the motion, suggested that the words "within the British Dominions" should be inserted.

This was agreed to.

Dr. Bruce pointed out that the effect of Scotland leading the van in public health was that Scotsmen were insisting more and more on taking advantage of the public health diploma. The increase in the registration was due to Scotland and Ireland.

The President remarked that the superiority of Scotsmen would be more marked when they extended this provision outside the United Kingdom.

Mr. Thomson said he did not see why men with experience who had obtained offices in the Colonies should be in a different position from that of men in the United Kingdom.

Dr. Bruce's motion was then adopted.

Report of the Education Committee.

Dr. Windle submitted the following report of the Education Committee.

I. Teaching without Examination.

In the May session of 1904 the following resolution was passed by the Council: That the Education Committee be requested to collect information and report on the question of the possibility of including certain subjects in the curriculum without requiring examination in them.

The Education Committee desires to report that it has endeavoured, though without great success, to elicit the information which the Council requested. It was, in the first instance, decided that it was not advisable that any licensing body should be asked whether, in its opinion, there were any subjects of the present curriculum which might be taught without being examined upon. The inquiries made were therefore limited to what had taken place in the past.

It appears that in some cases the following subjects—vaccination, ophthalmology, mental diseases, infectious diseases—whilst required as part of the curriculum, are not specially examined upon—that is to say, there is no separate examination in one or more of these subjects. At the same time, students are given to understand that questions on any or all of these subjects may form a part of one or other of the papers set at the examination. It cannot, therefore, be said that there is any subject in the curriculum at present which is definitely excluded from examination.

The Education Committee has also endeavoured to ascertain whether any light could be thrown on the subject by continental experience and in this connexion has to thank Dr. H. Frank Heath of the Education Department for the information and papers which he has been good enough to supply it with. It appears that there is no country in Europe in which the certificate of a professor as to satisfactory attendance is accepted in the Faculty of Medicine, or indeed in any other Faculty, in the place of an examination. The need for such a device for moderating the rigours of the examination system as it flourishes here has never presented itself, for with the possible exception of Sweden (where the system has certain resemblances with our own) the examination is never divorced from the teaching and the record of the student's work in the schoolroom, laboratory, and hospital is always a most important factor in the ultimate decision. There is a centralised external examination in medicine held in Brussels by representatives from all the universities in Belgium at which medical students from any one university may present themselves if they so desire.

It would appear that there are special local reasons which may account for this examination, which in any case is very unusual in its nature.

We are informed by Dr. Heath that the only real parallel to the methods pursued in the United Kingdom is the examination system of China.

The Education Committee has therefore to report that its inquiry has led to information of a more or less negative character save in so far that it has brought out the fact that the examination of students abroad is almost entirely—generally entirely—in the hands of those who have taught them. Some at least of those who are in favour of the system of permitting certain courses to be taken out without requiring an examination to be held in them would probably agree that no such course should be considered to have been satisfactorily followed unless the teacher of that course had certified that the student had passed his class examination Such a method it must be admitted would very closely resemble that in vogue on the continent

II Application from the University of London

Dr Windle moved that the report should be received and entered on the minutes

Dr **Norman Moore** seconded the motion

Dr **Mackay** said he thought the subject matter of the first part of the report was of the very greatest importance The whole question of examination and its relation to teaching had already been discussed by the Council and what they had heard was only a stage in the further illustration of the matter He would be the last to suggest that examinations should be done away with He felt certain that particularly with respect to the final subjects of medicine it was of the utmost importance that every licensing body should take care that those who received its licence were fully qualified for the work they took in hand He should be very much inclined *to have the final examinations of the different licensing* bodies very much improved and extended He thought those subjects mentioned in the report—vaccination, ophthalmology, mental diseases, infectious diseases—should all form an integral part and not merely a chance part of the examinations When they came to deal with the earlier subjects of the curriculum, which properly were only to be regarded as preparatory to the great final test of medicine, he thought the question of examination assumed a very different form indeed and that undue and over severe examination might tend to destroy the efficiency of the teaching in those subjects While it was of great importance, for instance, that students should have a knowledge of the principles of biology, if the subject was made examinable, and if during the three months, which was all that the greatest universities could devote to it, they compelled students to get up the subject, the students were forced from the outset of their curriculum to adopt a wrong method of study The methods of preparation for examination were very different from methods of real study The evils of examination did not lie with the General Medical Council because that matter was in the hands of the universities and other bodies and it was from them that the remedy must come The Council had done good in the past by directing the attention of bodies to the suggestions they had made The Council by keeping before it a distinct method in medical education could do a very great deal He would point out that the Council in the Acts which governed its procedure had power to inquire into courses of study held by the different licensing bodies and the various examinations of those bodies The Council had recently conducted an examination of the first professional examination and it was right that it should exercise the power if it had any reason to believe that the courses of study were not sufficient On the other hand, he did not think the Council should make a settled policy of examining the earlier examinations He feared that would increase the stringency of examinations and the difficulty of the medical students It should be only in exceptional cases that that work should be taken up by the Council He thought the Council was not in a position to go any further in its special efforts in this direction without having further information The matter was of the greatest importance and he thought they ought to find out what was the custom in the different countries of Europe and America and that at any rate the Council should know what other countries were doing in the way of medical education Though it was a difficult task still he thought the Education Committee if given sufficient time ought to be capable of fulfilling it The suggestion which he would afterwards put forward as a motion was that it should be remitted to the Education Committee to prepare and to present to the Council a detailed report upon the system of examination in medicine followed in other countries with the special object of determining the number of professional examinations demanded, the subjects included in these examinations, and the value, if any, attached to the records of class attendance and work He did not think this work could be accomplished speedily but in course of time the Education Committee would be able to report some very valuable information which would lead to good results

Dr **Lindsay Steven** said he had given this matter considerable attention and he had had the opportunity of bringing it before his constituents and discussing it with them The opinion he found to prevail in that part of the profession which he represented was that it would be an exceedingly dangerous thing to include within the curriculum either in the earlier part or the later part a compulsory course upon which there should be no professional examination Nothing had come out in this report by the Education Committee that had led him to disagree with that opinion or to alter his own personal opinion It was a dangerous thing to make compulsory courses in a curriculum and not demand a professional examination upon them

Dr **Pye Smith** said he wished to bring before the Council the subject of a junior schools examination which the University of London wished the Council to recognise as qualifying for the subject for which it was held The University of London asked that this school examination should from the point of view of the Council be on the same footing as the similar Oxford and Cambridge examination

Sir **William Turner** said that he would like some information Was this examination conducted by the University of London through examiners appointed for the *purpose and was it intended to take place* as a leaving certificate examination representing the state of knowledge of a boy of 15 or 16 ?

Dr **Pye Smith** replied in the affirmative and added, in reply to a further question, that the examination was not to occupy any position in the scheme of graduation

Dr **Windle** said that the matter ought to be explained fully The Consultative Committee submitted to the Council and other educational bodies a scheme which contemplated the holding of leaving examinations of two grades in secondary schools Those examinations presented several cardinal points—first, that they would be on the curriculum of the school secondly, that they would be held by the teachers of the school , and thirdly, that they were to qualify, if possible, for matriculation and other professional examinations The Consultative Committee only asked that the senior of those examinations should be accepted, in view of the examinations which the Council now accepted for entrance to the medical curriculum and not the junior one That was made clear at the conference Incited by this hope of the authors of the scheme universities had tried to arrange a similar plan and the University of London originally proposed a senior school leaving examination which it was prepared to accept, in view of its own matriculation That examination was brought under the cognisance of the Education Committee and the Education Committee at once accepted it because it was felt that as it was accepted by the University itself as the entrance to its own professional matriculation there could be no question of accepting it as the entrance to any other matriculation But they now came to this junior leaving examination which was not going to admit to any further examinations in the University of London So far as the student was concerned he was as absolutely an outsider in the University of London as if he had never presented himself for this examination and passed it But it was asked that this should be accepted as admitting students to other diplomas It seemed rather a curious procedure but it had a certain parallel in the examinations of the junior Oxford and Cambridge local That parallel was not so close as it would appear to those who were not quite familiar with the case The Oxford and Cambridge examination was accepted for a considerable number of years because there was a need It was an examination largely held in schools and it was held to be a great advantage not to compel those schools to take another examination and it had been accepted for some time as an examination qualifying for admission to the curriculum But of late years the junior local examination of Oxford and Cambridge had not been accepted as such The Universities of Oxford and Cambridge, desiring, however, that their examinations in schools should not fall out as qualifying examinations for medical students had arranged in connexion with the local examination a special preliminary medical examination which was held with it, but which was of a higher standard and more stringency The percentage of failures at that examination was about 60 per cent , whereas the percentage of failures in the junior examination was very much lower The Oxford and Cambridge local might be considered as equivalent to what was now proposed by the University of London, but that was not the examination the Council accepted but a totally different thing. What was pointed out in the letter that was being sent to the registrar of the University of London was that if the University of London chose in connexion with this junior leaving certificate examination to set up a medical preliminary examination as the Oxford and Cambridge Local Board had done the Education Committee then would be quite ready to examine the regulations and conditions of the examination and to accept it if it found it was of the scope and character which the Education Committee had been in the habit of demanding. This was only the first of a series of applications that would arise and the Council must have a policy. The Education Committee was quite clear as to what its policy was.

The PRESIDENT remarked that Oxford and Cambridge had also established junior schools examinations, but they had not applied for the recognition of these for the medical curriculum because they did not consider them up to the mark. These examinations were on the same level as the junior schools examination of the University of London.

The motion was agreed to and the report was received and entered on the minutes.

Dr. MACKAY then proposed his motion, viz. :—

> That it be remitted to the Education Committee to prepare and present to the Council a detailed report upon the system of examination in medicine followed in other countries with the special object of determining the number of professional examinations demanded, the subjects included in these examinations, and the value, if any, attached to the records of class attendance and work.

He said the motion only asked that their information should be more detailed and precise.

Sir JOHN BATTY TUKE seconded the motion.

Dr. PYE-SMITH said that with respect to Dr. Windle's exposition he had nothing to say against it, but while recognising the importance of keeping up those examinations to a high level he thought the examination as proposed by the University of London did preserve a high level of a school leaving examination. He could not, of course, pledge the Senate, but he might say that it would be the last to wish to lower the standard. The reply of Dr. Windle would enlighten them and pave the way, he thought, to an examination which would be acceptable to Dr. Windle himself.

Dr. WINDLE, referring to the motion before the Council, said that while such a report as Dr. Mackay proposed would be very interesting and useful it would be very laborious work to draw it up. The pith of the information which could be elicited by such a motion was really contained in the report of the Education Committee.

Dr. LITTLE remarked that the Education Committee was already overworked.

Several other members alluded to the great amount of work which Dr. Mackay was proposing to put upon the Education Committee.

Sir JOHN BATTY TUKE said that if they could bring their examinations down to one long final examination it would do a great deal of good to the student and a great deal of harm to the crammer.

Dr. MACKAY said the work did not require to extend to the length suggested. They might give a very useful summary of the method of examination in this country on a couple of pages and they might do the same in the case of America, Germany, France, and Italy.

With the leave of the Council the words "a committee" were substituted for "the Education Committee."

The motion so amended was put to the vote and rejected by 11 votes against 9.

Dr. LINDSAY STEVEN asked Dr. Windle whether the committee had anything to report on the remit of last November to consider whether the adoption by the Council of one or either or both of the following resolutions would not help to secure the attainment of the objects the Council had in view in instituting the five years' curriculum—viz., (1) that the preliminary scientific examination in physics, biology, and chemistry should be passed before the student begins the qualifying stage of anatomy and physiology; and (2) before being admitted to the final examination the student should produce evidence that he has devoted the last year of his curriculum exclusively to practical and clinical work and study.

Dr. WINDLE said the committee was not yet in a position to report on that matter.

The PRESIDENT said that no doubt the Education Committee would thank Dr. Lindsay Steven for reminding it of its duty.

Financial Report.

Dr. PYE-SMITH moved that the following report of the Finance Committee be received and entered on the minutes :—

> The Finance Committee have to report that the income of the General and Branch Councils for the year ending Dec. 31st, 1904, was £8062 0s. 6d. The expenditure for the same period was £8280 0s. 7d. Consequently there is a deficit on the year's working of £218 0s. 1d. Although there is a deficit the committee cannot but regard with satisfaction the fact that it compares so favourably with that of last year (£2165 1s. 8d.); indeed, with the exception of the year 1898, in which the Pharmacopœia was published and the receipts thereby abnormally increased, this is the first time since 1895 that the deficit has not exceeded £1000.
>
> Taking matters in detail it will be seen that the receipts from fees show a decrease of £115 11s., the English branch having received £93 5s. less, the Scottish branch £195 18s. 6d. less, and the Irish branch £173 12s. 6d. more. The sum received is practically the same as that received in 1902 (£6613 15s. 6d.) but the average for the past three years is about £400 a year less than for the previous three, notwithstanding the raising of some of the fees, the result of which is shown below.
>
> It will be remembered that in July, 1903, the fees for the registration of additional qualifications and for restoration to the Register were raised from 5s. to £1, and it is now possible to compare a full year at the new rate with the last year at the old rate as follows:—

	1902 No. of fees.	1904 No. of fees.	1902 Cash received.	1904 Cash received.	Increase.
			£ s.	£ s.	£ s.
English branch	569	... 404	... 142 5	... 404 0	... 261 15
Scottish branch	158	... 150	... 39 10	... 150 0	... 110 10
Irish branch	73	... 59	... 18 5	... 59 0	... 40 15
Total	800	... 613	... £200 0	... £613 0	... £413 0

> The English branch shows a decrease of 46 in the number of original registration fees received, the Scottish branch a decrease of 47, while the Irish branch shows an increase of 30, making a net decrease of 63. The average number of original registrations during the past seven years has been 154 less than for the previous seven and 92 less than for the seven years before that.
>
> Turning to expenditure it will be seen that there is a reduction of £2047 17s. 10d. and the following details seem to call for comment:—(a) The decrease of £1021 4s. in General Council fees is due to the fact that there were two sessions instead of three and that they lasted altogether for 13 days instead of 17. The reduced scale of travelling allowances tended to economy; but to balance this additional expenditure was entailed by the addition of two new members to the Council. (b) The increase of £39 3s. 3d. in various committee fees was caused by the meeting of the Preliminary Scientific Committee early in May. (c) The reduction of £75 4s. 9d. in the cost of printing the Medical and Students Registers is due to the smaller number of copies ordered in accordance with the resolutions adopted in July, 1903. (d) The cost of printing the programmes, &c., was reduced by £124 2s. 6d. and was the natural result of the shortened sessions. (e) Law expenses show a reduction of £78 1s. 7d. The Council was especially fortunate in having a small number of penal cases to deal with, none of which took up much time; unfortunately, three of the cases which came up were only postponed and will have to be heard this session. (f) The reduction of £287 8s. 2d. in the visitation of examinations is due to there being no inspection of primary examinations and also to there being only a small portion of the cycle to complete. (g) Miscellaneous expenses were reduced by £129 4s. 1d., partly because of the smaller cost of reporting penal cases and partly because in 1903 50 guineas were paid for the valuation of the Council's property.
>
> With regard to the income and expenditure of the three branch Councils for the past three years, with the small exceptions of the branch Council fees in Scotland and Ireland and the receipts of the Irish branch from registration fees, there is a reduction all round in income and expenditure; but it is satisfactory to see that each branch is doing what it can to balance the diminished revenue by keeping down expenses.
>
> It will be noted with satisfaction that the total assets of the [illegible] result branches are only reduced on the year's [illegible] which compares very favourably with th[illegible] shown in the previous year. It will be not[illegible] valued at about 90. The reason of this is that Consols [illegible] English branch in 1903 and 1904, but the auditors omitted to write off the difference between the price at which they were sold (91) and the price at which they had been valued (90), and consequently the state- [illegible]s that £9065 11s. 10d. Consols at 90 were [illegible]ctly accurate, though the difference is but [illegible] opinion that these differences should be written off as they arise. The Pharmacopœia accounts show that the funds from which the expense of publishing the next Pharmacopœia will be met are steadily, if slowly, increasing at the rate of about £200 a year.
>
> *Irish Branch.*—Assuming that the expenses for this year, including the contribution to the General Council, are about the same as those of last, say £1000, and the receipts do not fall below £850, there will be a deficit of about £150 on the year's working. Against this there is £111 in hand, and the committee recommend a grant of £100, should it be required, to make up the deficiency.
>
> *Dental Fund.*—The English branch having repaid the loan to it of £1200, this sum has been invested in Consols, of which £1367 10s. 5d. were bought at 87¾, bringing the total invested funds up to £8400. Since the close of the year a further sum of £660 3s. 10d. Consols has been bought at 90¾. The income for the year exceeded the expenditure by £435 19s. 1d.
>
> To forecast the expenditure for a year is most difficult, because the number and length of the sessions, which cannot be foretold, are by far the most important factors in the calculation. It should be remembered that the assembly and dispersal of the Council, exclusive

of all fees for attendance, costs £350, and that hotel expenses and attendance fees come to £200 a day, or 16s 8d a minute for the four

necessary to find about £1

*** At the conclusion of the surgical section of the visitor and inspector's report the following paragraph occurs —

"It did not appear that they had in any way suffered from having been arts and science students of a university which prescribes no special medical curriculum but which offers to its former graduates an examination for B.M. and B.C. degrees of such a high standard as we believe the examination we have inspected to be"

Mr. JACKSON said he wished to ask whether in the surgery examination there was no operation on the dead body. He thought that in such an examination there should be some proof that the student was able to use the forceps and the knife as well as other instruments Apparently there was no mention of operations on the cadaver and nothing was said with regard to diseases of the ear.

Sir CHRISTOPHER NIXON said that he was disappointed that no reference was made in this report to the former report presented to the Council on the inspection and visitation by the late Sir George Duffey and himself. The present report showed that Sir George Duffey and himself had the most ample justification for the comments they then made on the examinations of the University of Oxford. First of all they found fault with the way in which the clinical examination was conducted simultaneously in medicine and surgery so that there was not an opportunity for the visitor and inspector to make a report on both examinations. They further reported that the time was insufficient. The present report showed that there had been a complete alteration, the examinations being held upon different days and double the amount of time being given to the clinical examinations. The system of marking had been objected to and now there was a very complete and elaborate system. He also referred to previous comments on the lack of special examination in clinical microscopy and the deficiencies of the examination in surgical anatomy

Dr MCCALL ANDERSON said the visitor and inspector were only asked to give an opinion as to the sufficiency of the examination and it must be very gratifying to Sir Christopher Nixon to find that all the criticisms had been amply met by the University With regard to operations on the dead body the difficulty, of course, was with regard to subjects and the way this difficulty was met, as stated in the report, was the best substitute for actual operations on the cadaver. He pointed out that microscopic examination was made by every student and as to the absence of a report regarding a *viva voce* examination in forensic medicine he said that the report of the visitor and inspector showed that the examination in forensic medicine and hygiene was thoroughly practical. Though there was no separate *viva voce* examination the candidates were liable to be so examined. He expressed his recognition of the most courteous consideration which he and Mr. Bryant had received from the University authorities and concluded by referring to the examination as far above the requirements of the Medical Acts

Sir THOMAS MYLES said that the Irish bodies continued to attach the very highest importance to the actual operations on the cadaver He felt that they would be put in a position
y of
did

Dr. MCCALL ANDERSON said he agreed that there ought to be an examination in operative surgery but they could not make bricks without straw.

Sir WILLIAM THOMSON said that he thought it would only have been courteous to make some reference to the previous report. It would tend to point to the value of inspection and its results He thought it unfortunate that great institutions like the University of Oxford should be unable in carrying out its examinations to meet this so called difficulty in regard to operative surgery. He thought that if a little effort were made or a little regard had to the views sometimes expressed in the General Medical Council the matter would never again need to be referred to by any visitor or inspector. This was a matter in which he entirely agreed with Sir Thomas Myles. It was quite absurd to him to hear of tests being made as to proficiency in operative surgery which simply consisted in painting with a line of chalk on the living body or describing the outline of the operation. He held that the Council should insist on these substitutions for examination being put an end to.

Dr. **BENNETT** expressed surprise that ophthalmic examination was omitted from the examinations in practical surgery and found fault with the use of blunt instruments on the living body.

Mr. **MORRIS**, referring to the practice of the Royal College of Surgeons in London, said that operations on the cadaver took place in the Fellowship examinations, but from their experience the examiners had one and all formed the opinion that very little value attached to that form of examining candidates for the Membership.

Sir **VICTOR HORSLEY** said he understood that Mr. Morris was speaking for the Council and not for the College as a whole. If he submitted this question to the Royal College of Surgeons he would find that the Fellows and Members did not agree with him. Most of them thought that the absence of operations in the examinations for operative surgery was a great blot on the joint examination.

Sir **JOHN W. MOORE** expressed the opinion that when a visitation had resulted as it had done in the case of Sir George Duffey and Sir Christopher Nixon some recognition of it ought to be made in the present report.

Dr. **NORMAN MOORE** thought it would form a very bad precedent if the Council were to congratulate itself on the result of its efforts. It should rest in dignified satisfaction.

Dr. **McVAIL** said there was not the slightest reflection on the truth of the report of the former visitor and inspector in the report now before them and it was not always advisable to say how a change had come about. There could be no doubt that the examination was in every way satisfactory. As to the lack of a formal examination in ophthalmology he noticed that the eye was mentioned in the examination papers. In medicine the ophthalmoscopic examination included the following: cases—normal eye, opaque nerve fibres and high myopia, persistent hyaloid, keratitis.

The **PRESIDENT** said that in a number of reports before the Council criticisms were made on particular parts of particular examinations. It was not to be assumed that the Council ignored those criticisms. They would come up for consideration when the final report of the Examination Committee on the whole cycle was brought up. They could not deal fairly with one examination at a time. They must deal with them all and he would add that this examination at Oxford was not the first regarding which criticism had been made in connexion with operative surgery.

Mr. **THOMSON** said it must be a matter for congratulation on the part of the graduates of the University of Oxford that now they were reinstated in the good graces of this worthy Council. He did not assent to the view that the standard of the Oxford examination had been raised in the way in which certain members suggested. The standard had always been a high one. Their candidates had to pass the qualifying subjects in medicine, midwifery, and surgery at one and the same examination. They were not permitted to take it piecemeal. He admitted that the character of the examination had been altered but not the standard. It had been altered so far as the method and routine of the examination were affected. It was easy to come down to Oxford and say this or that was not so good as it ought to be but they had to consider the difficulties of the situation. All their examiners in the final subjects might be regarded as extern examiners. They were not resident with the exception of their Regius professor. The students suffered no inconvenience by the arrangement of the examinations. It was a serious matter to ask men to come from all parts of the country to waste three or four days when they might overlap the subjects and save time. Such overlapping was not a justification for suggesting that an examination was not sufficient. Members of the Council would remember certain instances being brought forward as instances of the leniency of this examination. One of the men who in the previous report was regarded as a weakling was one who by research and the practice of his profession had attracted not only the attention of the profession but that of the public as well. He wished that all the insufficients were as capable. He had nothing to do with the last report but certain observations had been made on the present occasion which rather led one to assume that serious changes had been effected in the character of this examination. It was pointed out that a system of marks was in operation, but this was a mere suggestion put down so that the examiners might have something to go by. The University had no intention of requiring its examiners to conform to a hard-and-fast system. The examination had been made a little more methodical but the general standard had not been altered. It seemed a source of satisfaction to Irish members to tell them many of the virtues of their examinations in operative surgery. He would not venture to express any opinion in this matter. He must leave it to the surgeons in this country but he might say that there seemed to be no unanimity on the subject. If the Council liked to make recommendations it must also provide the facilities by which those recommendations were to be given effect to. He would point out that Oxford also in its senior examination for the Mastership of Surgery examined every candidate on the cadaver. With regard to the lack of special examination in ophthalmology and so on after what Dr. McVail had pointed out and considering that the examination was taken at one time, he did not think that could be called a serious defect in the examination. The candidates were liable to be asked questions on those subjects.

The motion was then agreed to and the report of the Examination Committee was approved.

The Final Examination of the University of London.

Sir **PATRICK HERON WATSON** submitted the report of the Examination Committee on the reports by the inspector, Mr. Thomas Bryant, and the visitor, Sir John Batty Tuke, on the final examination for the degrees of Bachelor of Medicine and Bachelor of Surgery of the University of London. He moved that it be received and entered on the minutes.

Mr. **YOUNG** seconded the motion, which was agreed to.

The report was in the following terms:—

The inspection and visitation of the final examination of the University of London, held in October and November, 1904, is reported on separately by the inspector, Mr. Thomas Bryant, and the visitor, Sir John Batty Tuke. The report by the inspector extends from page 6 to page 15; that by the visitor is comprised in one paragraph on page 15.

The inspector was present during the examinations in oral medicine, clinical medicine, oral surgery, clinical surgery, surgical pathology, surgical an[illegible] [illegible]y, forensic medicine, hygiene, a[illegible] [illegible] He also read some of the candidates' answers in the written exa[illegible] in all the subjects. The visitor was present along with the inspector on two days of the clinical surgical examinations.

The inspector reports that the examination was "sufficient." The visitor reports that it was "sufficient" and of "high quality." The inspector commends the written questions in medicine, surgery, midwifery and gynæcology, pathology, forensic medicine, and hygiene; and as regards most of the candidates' papers he was well satisfied and he nowhere dissents from the marks that were awarded. He states that the oral examination in medicine was "very thorough"; in surgical pathology it was "excellent" and "of a high order;" in surgical anatomy and appliances "good"; in pathology "excellent and searching"; in forensic medicine and hygiene "a very searching one"; and in midwifery and gynæcology "a very full and practical one." Regarding clinical surgery h[illegible] [illegible]tion was high in standard. In clinical medicine he [illegible] [illegible]. Geo[illegible] [illegible], much stress being laid upon metho[illegible] [illegible] of these was less satisfactory owing to [illegible] her physician at short notice taking his place; the cases were few and scattered and during part of the time friends of the patients were present in the ward.

At the oral examinations in medicine, clinical surgery, surgical pathology, surgical anatomy and appliances, each candidate was examined by one examiner only. In pathology each of the two examiners examined every candidate at separate tables and conferred as to the marks to be awarded. This was also the arrangement in forensic medicine and hygiene and in midwifery and gynæcology. Concerning this method of examination the inspector remarks as follows:

"The only [illegible] to be made has reference to the following [illegible] neral Medical Council: 'A candidate sh[illegible] except in the presence of two examiners. [illegible] this examination the recommendation, as taken in its ordinary sense, was *ignored*; for the *viva voce* examination was invariably conducted by a single examiner, who himself fixed the marks awarded *to* the candidate. Where two examiners divided the time allowed for the examination between them the final mark was given after a conference between the two; but in all other instances the results of the examination were decided upon by one examiner on his sole responsibility. In another university which has been inspected an *interpretation* is given to this recommendation which differs widely from that usually accepted. In view of these facts it appears to the *inspector* that the Council should consider in what sense the recommendation is to be interpreted, for it is quite clear that where the number of candidates is large the difficulty of carrying it out, at least in the sense in which it is understood the Council intended, would be great and the expense heavy. Where all the examiners are of a high order the presence or absence of a second examiner or assessor may not always be of much importance. But it is easy to imagine conditions in which the absence

Sir **PATRICK HERON WATSON** moved that the report be approved.

Mr. **YOUNG** seconded the motion.

The **PRESIDENT** said the motion implied that one point was reserved for the consideration of the Council and that it would come up again in connexion with the whole system of examinations, in some of which a difference of interpretation had been noted.

The motion was agreed to and the report was approved.

Final Report on Cycle of Inspection.

Dr. **McVAIL** moved to remit to the Examination Committee to prepare and present to the Council at its May session next year a general report on the whole cycle of visitations and inspections of the final examinations.

Sir **JOHN W. MOORE** seconded the motion.

Dr. **PYE-SMITH** said that unless they had some use for this general report they ought to let the matter rest with the good that had been done. They had all the reports on the minutes.

Sir **VICTOR HORSLEY** said that the Council had a duty to perform—namely the co-relation under the Act of 1886 of medical education throughout the country. Until they had digested all those reports and agreed what should be the status of medical education they had not done their duty under the Medical Acts.

Sir **JOHN W. MOORE** said that important matters such as the practice of operative surgery had been kept over till they considered the general report.

Dr. **MACKAY** said that it was the duty of the Council to co-relate the results and put them together before they started on a new cycle of inspections.

The **PRESIDENT** said that he thought the Council was bound to have a general report because of some of the matters being left over for discussion.

The motion was carried by a large majority.

The Navy, Army, and Indian Medical Services.

On the motion of Sir **PATRICK HERON WATSON**, seconded by Dr. **LITTLE**, the following report of the Examination Committee on the statistics relating to the examinations of admission to the Navy, Army, and Indian Medical Services was received and entered on the minutes.

a circular letter to the

the percentage of rejecti

regularly to consider the

the Council such suggestions as occur to them.

On the motion of Sir **PATRICK HERON WATSON**, seconded by Mr. **BROWN**, the recommendation of the committee was adopted.

Report of the Pharmacopœia Committee.

Dr. **NORMAN MOORE**, on behalf of the President, in moving that the report of the Pharmacopœia Committee be received and entered on the minutes, said it contained no contentious matter and no recommendations.

The motion was seconded by Sir **JOHN W. MOORE** and agreed to.

The report was as follows:—

From

Pharmac

has alre

one time.

The committee desire to record their sense of the loss they sustained by the death of Dr. Tichborne, whose keen interest in the Pharmacopœia and whose personal labours for its improvement were greatly valued by his colleagues.

During the past year the committee have had under consideration the question of organising, in a more systematic fashion than has

several years past, were then added as additional members. To the body of experts so appointed, and now at work, various questions

harmacy in general

year has been set

ceting of the com-

mittee of reference on pharmacy, which was held on Feb. 23rd, Mr. Walter Hills was chosen as chairman and Professor Greenish was appointed secretary. At this meeting the President and Dr. Tirard, secretary of the Pharmacopœia Committee, were present and gave explanations as to the inquiries contemplated and the methods suggested

posals that may be made to them by any of their committees or

Report of the Dental Committee.

Mr. **TOMES** moved that the following report from the Dental Education and Examination Committee be received and entered on the minutes. This was seconded by Mr. **BROWN** and agreed to. The committee reported:—

A communication has been received from the University of Dublin (Trinity College) notifying the General Medical Council of the establish-

degree in dental science, as well as of a Licentiateship in

UNIVERSITY OF DUBLIN.

LICENCE IN DENTAL SCIENCE.

It is not proposed to throw open this examination to students who have wholly or in part studied elsewhere, except in the case of qualified persons or others who may desire recognition of courses taken

lishment of the degree or licence The public

The final examina

dental surgery and pathology, dental mechanics orthodontia.

Whilst the amount of study required of the student shows a general correspondence with that prescribed by other bodies it is somewhat

attendance at a general hospital

to him, for the necessities of the case bring it about that he must attend clinical instruction at a period when the ordinary medical student is not doing so; and, further, he is not examined in medicine and surgery till two years or thereabouts after his attendance on these subjects has ceased. There are only two examinations, physics and chemistry being included in the first, which results in its embracing a very considerable range of subjects. The student is, however, allowed to pass them in groups.

DEGREE IN DENTAL SCIENCE.

This has the same curriculum as that for the licence, with the addition of lectures on pathology, practical pathology, and bacteriology, which should be taken out in the fourth or fifth year. All candidates must have passed for the B.A. degree and must have been students of the medical or dental schools for five years. The previous dental examination is the same but the final examination embraces the additional subjects of pathology and bacteriology. The possession of the degree (M. Dent. Sc. Univ. Dub.) *may therefore be taken to imply a higher* general culture.

VICTORIA UNIVERSITY OF MANCHESTER.

DIPLOMA IN DENTISTRY (L.D.S. MANC.).

The preliminary examination is to be such as is required by the General Medical Council for registration as a dental student.

A curriculum of four years' duration subsequent to registration is required and studies are divided into four courses with examinations at the end of each.

The first course embraces chemistry and physics which may have been studied prior to registration and at any institution recognised for the purpose by the University.

The second course embraces metallurgy and dental mechanics; the [illegible] at an approved dental hospital for two years [illegible] late of registration, or by apprenticeship to a [illegible] the first examination must have been passed.

The third course and examination embraces anatomy, physiology, and dental [illegible] These may be any courses recognised b[illegible]

The fourt[illegible] comprises surgery, operative dentistry, and dental surgery, and prosthetics. Clinical instruction at *a general hospital must have extended over 12 months and the practice* of a registered dental hospital over a period of two years.

It will be noticed that this scheme differs markedly from that of the Dublin University. No part of the instruction is required to be taken out at the Victoria University, so that the examination for the diploma is absolutely thrown open to candidates educated at recognised schools elsewhere.

There are four examinations in the place of two; and though it is not expressly so prescribed, the natural result of the arrangement will be that the attendance at a general hospital and upon the general subjects taught there will be taken in the fourth year.

DEGREE OF BACHELOR OF DENTAL SURGERY.

A period of five years of study is required subsequent to registration. The same matriculation examination as that required by the Faculty of Medicine must be passed.

The first course and examination differs from that required for the diploma, in that zoology is added, and the period of instruction is 12 months instead of six, and must be taken in the University.

The second course and examination differs little from that required for the diploma but must be partly taken in the University, and the same applies to the third course and examination, except that all must be taken at the University.

The fourth course can be taken out at other recognised schools or at the University, and embraces surgery, pathology, including bacteriology, clinical medicine and surgery, dental surgery and pathology, three years of dental hospital practice, and an additional year of work in the mechanical laboratory of a recognised dental hospital, &c. Persons qualified before October, 1905, who have pursued their studies at Owens College or at the University may be allowed to obtain the degree of Bachelor of Dental Surgery after passing the third and the final examinations without any additional study, a concession not beyond question in respect of a "higher" degree. The degree of Master of Dental Surgery may be obtained either on presentation of a thesis or by examination on certain dental subjects or groups of subjects as yet undetermined.

The degrees, therefore, are confined to those who have, to a considerable extent at all events, studied in the University.

Special courses of lectures on the surgery of the mouth, on dental bacteriology, and on dental materia medica are not represented in the curriculum for the licence, though *such courses are required, for* example, by the Royal College of Surgeons of England for their licence.

It appears to your committee desirable that degrees "in respect of a higher degree of knowledge" should be granted to those persons only who are already possessed of a registrable qualification, a course which appears to be indicated by the words used in Section 11 (6) of the *Dentists Act.*

DENTAL BOARD OF VICTORIA, AUSTRALIA.

A letter has been received from the Dental Board of Victoria expressing their gratification at the recognition of their diploma and their cordial agreement with the conditions attached thereto. They ask for information as to the returns made to the General Medical Council by the licensing bodies of the United Kingdom and fully recognise the necessity of some test of the sufficiency of their examinations which, owing to distance, cannot be inspected like those of the licensing bodies at home. They offer, should the Council desire it, to retain for 12 months the examination papers, returns, &c., and to forward them to the Registrar. Powers of visitation of their examinations [illegible] to the University of Melbourne. They point [illegible] on of the statistics as to the proportion of pa[illegible] obtain at home might not be perfectly fair to a school as yet small and at the moment possessed of an unusually competent body of students.

RECOMMENDATIONS.

(i.) That the registrar be instructed to accept for the purposes of registration upon the Dentists Register the licence in dental science of the University of Dublin and the licence in dental surgery of the Victoria University of Manchester (Dentists Act, Sec. 6 (*a*)).

(ii.) That the degrees in dental *science and in dental* surgery granted by the same universities be recognised for entry upon the Dentists Register as "additional diplomas, memberships, licences ...... granted [illegible] knowledge" (Dentists Act, Sec. 11 (6)).

[illegible] sitation in the ordinary sense being at [illegible] fer of the Dental Board of Victoria (Australia) to submit candidates' papers, marks, and returns generally to the registrar be accepted.

Mr. TOMES moved the approval of the first recommendation which was seconded by Dr. BENNETT and agreed to.

Mr. TOMES moved the approval of the second recommendation which he said was necessary in accordance with the Act.

Dr. LINDSAY STEVEN seconded the motion.

Sir WILLIAM TURNER asked whether there was not likely to be some confusion in the introduction into the university system of a licence which was to be given precedent to the conferring of the degree.

In the course of further discussion,

Mr. YOUNG stated that those degrees would be subject to visitation and inspection at any time, and

Sir JOHN W. MOORE remarked that the degree at the University of Dublin was only to be given to bachelors of arts.

The recommendation was approved.

On the motion of Mr. TOMES, seconded by Dr. LINDSAY STEVEN, the third recommendation was agreed to.

Mr. BROWN moved:—

> That the President be authorised to take the opinion of the legal advisers of the Council as to whether degrees granted in dental science and dental surgery by universities in the United Kingdom are registrable as primary qualifications to practise dentistry.

He said it was obvious that some such decision was called for.

Mr. JACKSON seconded the motion, which, after some discussion, was adopted.

Canvassing and Advertising.

On the motion of Dr. WINDLE, seconded by Sir VICTOR HORSLEY, the following communication from the British Medical Association was received and entered on the minutes:—

Offices of the British Medical Association,
429, Strand, W.C., May 22nd, 1905.

SIR,—In pursuance of a resolution of the Council of the British Medical Association, con[illegible] thical Committee of the Associati[illegible] Council to [illegible] to medical [illegible] sing for the [illegible]

Cases are constantly brought un[illegible] Association of such canvassing and [illegible] or by lay bodies by whom medical [illegible] of door-to-door visitation, distribution of cards and handbills, or newspaper notices. These cases have been [illegible] Ethical Committee of the Association. [illegible] concerned have been asked to give such [illegible] for the assistance of the committee in considering whether the cases should be reported to the General Medical Council. The reply repeatedly received has been that the medical practitioner was not aware that there was any professional objection to such canvassing or advertising.

We forward, as an example, the correspondence of the *committee* with a practitioner whose name, address, surgery hours, and fees were printed on cards which were distributed in the neighbourhood of his residence, and who, it will be seen, pleaded that he was not aware of any objection to such distribution. We inclose also copies of cards, handbills, and newspaper adve[illegible] which have at times been brought to the notice of the Et[illegible] appear to that committee to be [illegible]

The Ethical Committee and [illegible] ciation would submit for the [illegible] Council:—

(1) *That advertising, including canvassing*, by medical practitioners for the purpose of procuring patients is injurious to the interests of the public as well as of the medical profession and that the disciplinary powers conferred upon the General Medical Council for the public [illegible] XXIX. [illegible] Medical Act, 1858, would be [illegible] Council declaring [illegible] ng for the purpose [illegible] r notices, or other [illegible] means;

(2) That although, as the Association recognises, the General Medical Council possesses no statutory authority to formulate by-laws [illegible] can only deal with for [illegible] ts, nevertheless the eac[illegible] to time declaratory act[illegible] 1897, and June 6th, res[illegible] nqualified assistants 189[illegible] nvass and advertise) an[illegible] present case appears ha[illegible] *to be one in which* to [illegible] the [illegible]

(3) That the issue of such a notice would not only be helpful to those medical practitioners who, under present conditions, are actually ignorant of the past decisions of the General Medical Council in cases of canvassing and advertising, and thus inadvertently offend, but

would deprive those who deliberately offend of an excuse which they at present put forward

We are, Sir your obedient servants

Medical Secretary

edical Education and

Dr WINDLE moved—

That the communication from the British Medical Association especting the desirability of issuing a general warning notice to

the next meeting of Council

He thought this would be the best manner of dealing with a matter which should be left not to the General Medical Council but to the Executive Committee and the legal advisers

Sir VICTOR HORSLEY in seconding the motion, said that now that they had had several concrete cases of advertising brought before them it was time the Council should consider whether it ought not in its wisdom to issue a decree

Dr LINDSAY STEVEN supported the motion He was glad the medical authority of the British Medical Association had been brought to bear on this question About a year ago he proposed a motion on similar lines but withdrew it They had now additional facts before them and they had this important communication from the British Medical Association so that there should be no difficulty now in remitting the matter to the Executive Committee

The PRESIDENT said he agreed that they had had sufficient experience of the vagaries of the gentlemen likely to be touched by this motion and they ought to proceed to formulate something

The motion was agreed to

Remuneration of Members of Council

Mr BROWN moved that from and after July 1st next the remuneration for attending meetings of the Council and Executive Committee should be three guineas per diem instead of the standing orders be

in order that the question should be decided upon

The motion was rejected only the mover and seconder voting for it

Appointment of Assistant Examiner

On the motion of Sir HUGH BEEVOR seconded by Mr MORRIS it was resolved that Mr W McAdam Eccles F R C S be appointed as assistant examiner in surgery to the Apothecaries Society of London for a period of four years, vice Mr W Bruce Clarke who retires by rotation

The Council adjourned

SATURDAY MAY 27TH

The Council resumed, Dr MACALISTER the President, being in the chair

Direct Representation on the General Medical Council

Mr BROWN moved that representations be made to the Privy Council that the time has arrived when the number of Direct Representatives for England Scotland and Ireland should be increased to the maximum number permitted by the Medical Act 1886 He contended that the medical profession of the United Kingdom deserved to be more adequately represented than they were at the present time The powers he asked the Council to exercise were contained in Section 10 of the Act which provided that the General Medical Council might at any time represent to the Privy Council that it was expedient to confer on the medical practitioners resident in any part of the United Kingdom the power of returning an additional member to the General Medical Council That meant that they had the power of representing that England and Wales, Scotland, and Ireland should each return an additional member At present there were only five. When the Act was passed the membership of the Council numbered 30 but they had recently had additions and it was now 33 Accordingly the direct representation had diminished in proportion to the whole representation since 1886 Besides new universities were being started and he had no doubt that they would expect to be represented on the Council That was one reason why the direct representation should be increased Another reason was the considerable increase in the number of registered practitioners In the year 1886 there were 17 000 medical men registered in England There were now more than 21 500 In 1886 there were 5000 registered in Scotland At present there were 11 000 In Ireland the number had increased from 4317 to 5267 Looking at the Medical Directory they found that in England and Wales there were practising in 1886 17 395 compared with 24,351 at the end of last year showing an increase of 7000 The time had arrived, he thought when they could fairly claim additional representation

Mr JACKSON, in seconding the motion, said that in many instances new universities that might obtain representation on the Council must represent only a small number of graduates In these circumstances they had a right to ask for additional representation for the thousands of practitioners to whom Mr Brown had referred He submitted that there were certain points which the universities looked at from a different point of view from that of the practising medical man

Sir JOHN W MOORE said that so far as Ireland was concerned it had consistently returned as its Direct Representative a gentleman who was most intimately connected with two of the licensing bodies in that country and a member of the governing bodies of both He thought that was an unanswerable argument against the views put forward by the proposer and seconder The licentiates of the Irish College of Physicians had only to make representations to the College and they would be treated with the utmost courtesy and their views presented to this Council

Sir VICTOR HORSLEY said that he would recommend Sir John Moore to take a plebiscite on the subject The method to which Sir John Moore referred would not satisfy the licentiates of the Colleges in England The question was not one of accommodation in their present room, it was a question of logic and justice Mr Brown and Mr Jackson had furnished them with the logical argument As regarded the claim of justice he would point out to the representatives of the new universities that they sat on the Council on a claim of justice He therefore asked their vote on behalf of the motion

Dr LITTLE said that the Council was if anything too large and the work would be better done if it were smaller He did not agree that the interests of the practitioners throughout the country were not to be safeguarded by him because he was not a direct representative He was sure that those members who were chosen by the various universities and corporations had the interests of their graduates and licentiates at heart just as much as if they had been directly represented He could not support the motion

Dr BRUCE remarked that since the Direct Representatives were introduced more had been done in the way of calling attention to the practising of unqualified men than was done before He supported the motion

Sir CHRISTOPHER NIXON said he took it that the members who represented the profession directly were quite competent to bring before the Council any interest that concerned the profession at large He did not see how they would gain anything by multiplying the representation of the profession which was so efficient at the present time They were all concerned in the interests of the general practitioner

Dr MCVAIL remarked that since the Act of 1886 was passed the profession had nearly doubled its ranks The education and the status of the profession had enormously improved and these facts alone warranted increased representation If Parliament were now considering the constitution of the Council anew he could not doubt that it would consider the direct representation given in 1886 to be insufficient now They could alter their accommodation if they introduced more members and there were various ways of improving the Council s finances He himself was prepared to abolish fees to members altogether

Sir WILLIAM THOMSON said that a justification for this increase in the representation would be the increased number of the general body of the profession Mr Brown had put the matter very fairly and temperately and the time had come when a claim might be made So far all the increase in representation had been one sided

Dr NORMAN MOORE said that he, as a representative of a corporation, did not come there to represent the private interests of the Royal College of Physicians, but that body had chosen him as a proper person to be concerned in the business of the Council and he thought that was the general feeling of other representatives of universities and corporations. He had never heard an appeal to the particular interests of anybody from any member of the Council. As to the improved character of the profession the Council had a share in the general education of the profession but it was only one of the great many forces which had produced the improved condition. The spread of universities, the greater intensity of work in the universities, the general improvement of education, and the greater consideration of education throughout the country had been influences. There was a strong reason against having an addition to the direct representation. The Council was established for the purpose of considering a variety of questions mainly surrounding education, training, and conduct. In order to select people who should discuss those matters a method of election which enabled the electing body to know everything about the persons it was to choose was most important. The object was to have skilled men who would be capable of dealing with complicated problems and who would be absolutely trusted to do so. They had been most fortunate in the direct representatives with whom they had had the honour of sitting, but he thought it was a surprising thing that they should have been so fortunate when they considered how little the constituents could know about them. The universities had another important advantage and that was that their choice was not confined to the opinion of the Medical Faculty. That was an influence which was of great advantage and importance to the Council. He would vote against the proposition.

Dr. LINDSAY STEVEN said that while he must admit the great force of the arguments which had been brought forward by Mr. Brown in support of his view of the case, at the same time he felt upon this occasion, at least, that he could not vote for the matter one way or the other. He quite agreed that the Medical Acts gave the Council the right of recommending in such a matter, and certainly the great increase in the numbers of the profession that had taken place in the last 10 or 15 years would seem to justify the consideration of the matter, but he did not believe that there was any great demand on the part of the general practitioner for additional representation at the present moment. He should have thought that if such a demand existed a much larger percentage would have taken the trouble to vote in recent elections to the Council.

Dr. CATON said it seemed to be implied that those members of the Council who were chosen by universities or corporations came chiefly and essentially to protect the interests of those universities and corporations. He should like for himself and his colleagues to say that they came chiefly and essentially to support the honour and dignity of the profession and that they were all representatives of the profession. They tried to do the same work as the direct representatives.

Mr. BROWN said he quite agreed that the representatives of the universities and corporations came to the Council to promote the interests of the profession generally but he maintained that the present proportions did not satisfy the profession generally.

On a division the motion was defeated by 8 votes. 10 voted for the motion, 18 against, and 5 did not vote.

Rules regarding Midwifery Practice.

Sir JOHN WILLIAMS moved :—

> That a committee of the Council be appointed to inquire into the operation of the rules regarding the midwifery practice required of candidates for medical qualifications.

He said that years ago the mortality from sepsis after delivery was pretty much the same as to-day. In 1876–80 it was 1·7; in 1881–85, 2·8; in 1886, 2·4; in 1891–95, 2·5; in 1896–1901, 2·0. This mortality ought to be absent and his object was to have an inquiry into the reasons for its continuance.

Dr. MCVAIL seconded the motion which was agreed to.

The committee was appointed as follows: Sir John Williams (chairman for convening purposes), Dr. McVail, Mr. Jackson, *Dr. Barrs, Dr. Caton, Mr. Young, and Sir C.* Nixon.

Executive Committee.

The Executive Committee was constituted as follows: Sir Hugh Beevor, Dr. Pye-Smith, Mr. Young, Mr. Tomes, Sir John Batty Tuke, Sir P. Heron Watson, Sir C. Nixon, and Sir William Thomson.

Penal Cases Committee.

The following were elected members of the Penal Cases Committee: Sir Hugh Beevor, Dr. Windle, Mr. Tomes, Sir Victor Horsley, Sir P. Heron Watson, Dr. Finlay, Sir C. Nixon, and Sir William Thomson.

Students' Registration Committee.

On the motion of Sir HUGH BEEVOR the report of the Students' Registration Committee on applications for exceptional registration as students or for antedating the commencement of professional study was approved and placed on the minutes.

Procedure in Penal Cases.

Sir WILLIAM THOMSON proposed :—

> That the Executive Committee be requested to consider, in consultation with the legal assessors of the Council, the question of amending the notice of inquiry in penal cases so as to enable the Council in cases where more than one charge is brought forward to come to a decision on each charge separately.

Dr. NORMAN MOORE seconded the motion. He said this procedure would enable the Council to arrive at a decision with greater precision in some of the cases that came before it.

The motion was agreed to.

Fee suggested for Students' Registration.

Dr. MACKAY moved :—

> That it be remitted to the Finance and Executive Committees to take into consideration the suggestion made by the President in his address at the opening of the present session to the effect that a small fee might with advantage be charged for students' registration.

He said that the subject was important and the quarter from which the suggestion came seemed to make it almost imperative that it should not be lost sight of.

Dr. LINDSAY STEVEN seconded the motion.

Dr. NORMAN MOORE said he hoped the motion would not be pressed at this meeting of the Council. He could not help feeling a doubt as to the expediency of making such a charge. Students' registration was entirely a private matter of the Council. The Council thought the registration was a useful thing but it was entirely unnecessary for any student in any part of the United Kingdom to place his name on the Register. To charge a fee, therefore, would be making use of a false impression that such registration was necessary; it would not be perfectly honest.

Sir CHRISTOPHER NIXON said that all the motion did was to refer the matter to the two committees for consideration. By passing the motion the Council did not commit itself to anything.

Sir PATRICK HERON WATSON said that such a proposal could hardly be carried out without the sanction of the Privy Council.

Mr. BROWN supported the view taken by Dr. NORMAN MOORE.

Dr. MCVAIL contended that nothing but an Act of Parliament could give the Council this power.

Dr. BRUCE said that while it was true that the Council could not insist upon registration surely if a student preferred to put his name on the Register he should be asked to pay the fee.

Sir JOHN BATTY TUKE expressed the opinion that it would be very inexpedient to charge a fee to which the Council had no right and he feared that such a thing would tend to break down the system of the registration of students which was a most useful part of the machinery of the Council.

Dr. PYE-SMITH questioned whether it would be creditable to a public body like this to make a demand which it had no power to enforce.

Sir WILLIAM TURNER said that certain bodies had taken up the attitude that they would not demand registration on the Students Register from those who appeared before them as candidates for their diplomas. But these bodies were a small minority and the great bulk of the medical authorities were in harmony with the Council on this matter and required of the candidates that they should be on the Register a certain number of years. A very large percentage of those who obtained admission to *the Medical Register* had been on the Students Register. This registration of students involved a charge on the funds of the General Medical Council; the Council was spending about £400 to carry out this registration to which the great bulk of them attached the utmost importance and therefore he thought they would be justified in exacting what was described in the motion as a small fee Of course this did not imply that the registration was to be compulsory They had no power to make it compulsory, he only wished they had

Sir **Victor Horsley** said that what the Council voted for in 1904 was the question of placing this matter in the Act by a specific clause and the Council determined to ask the Privy Council to do this very thing Therefore for this Council not to accept the present motion would be to stultify itself and also in a sense to stultify its belief in the registration of students a belief it had held for years He could not see any objection to the motion from any point of view, either from that of expediency or that of legality

The **President** explained that Dr Mackay in bringing forward this question had acted on his own responsibility All he would say upon it was that he did not think that the idea was such a very bad one that it ought to be condemned unheard

Dr **Little** did not think a small fee would deter anyone from registering People, as a rule, valued most what they had to pay for

Dr **McVail** said that in his reference to a vote in 1904 Sir Victor Horsley did not mention that in November the Council rescinded the whole affair

Sir **Victor Horsley** We did not rescind the whole affair in November, we only did not proceed further into the matter in consequence of a letter from the Privy Council

The motion was carried by a large majority

Diplomas in Public Health.

Dr **Bruce** moved and Dr **Norman Moore** seconded that it be recorded in the minutes that recommendations of the Public Health Committee as to the rules for diplomas in public health already adopted were additions to those rules but involved no further alterations in them

This was agreed to

Appointment of Committees

The following committees were appointed —

Examination Committee —By the English Branch Council Dr Pye Smith Mr Young and Dr Caton, by the Scottish Branch Council Sir P Heron Watson, Dr Finlay and Dr McVail, by the Irish Branch Council Dr Little Sir W Thomson and Sir T Myles

Education Committee —By the English Branch Council Dr Windle Dr Norman Moore and Sir G Philipson, by the Scottish Branch Council Dr Mackay Sir John Tuke and Dr McCall Anderson, by the Irish Branch Council Sir W Thomson, Dr Bennett, and Sir C Nixon

Public Health Committee —By the English Branch Council Sir G Philipson, Mr Power and Mr Jackson, by the Scottish Branch Council Dr Bruce, Dr Lindsay Steven and Dr McVail, by the Irish Branch Council Dr Bennett and Sir John W Moore

Pharmacopœia Committee —The President (chairman) Dr Norman Moore Sir George Philipson Sir J Batty Tuke Dr McVail Sir John Moore Dr Little, Dr Caton and Dr Barrs

Finance Committee —Dr Pye Smith (chairman) Mr Tomes, Sir P Heron

Dental Committee rris
Mr Tomes Sir P H

Dental Education and Examination Committee —Mr Tomes)r Lindsay
Steven Myles

Stud igh Beevor (chairman) Sir J Batty Tuke Dr Mackay, Dr Bennett, Sir William Thomson, and Dr McCall Anderson

Re-election of the General Registrar

On the motion of Dr **Windle** Mr Allen was re elected registrar

Vote of Thanks to the President

Dr **Norman Moore** moved that the best thanks of the Council be given to the President for his able services in the chair during the present session

Sir **Thomas Myles** seconded the motion, which was carried by acclamation

The **President** I cannot help thanking you very sincerely not only for the way in which you have aided me to day but for the uniform help you have given me by your sympathy and your willingness to excuse my inexperience

This concluded the business and the Council rose

MEDICAL DEFENCE UNION

Mr M A Messiter, the President of the Medical Defence Union, took the chair at the annual general meeting of the members of the union held at 11, Chandos street, London, W, on May 25th In moving the adoption of the report of the council the President congratulated the members on the success of the union and on the satisfactory report for the year 1904 Only two cases under the Medical Acts had been brought before the courts during the last year Several other cases had been fully considered and evidence obtained, but such evidence was not felt to be sufficiently precise to warrant summonses being issued and process instituted The "state of fog by which the present Medical Acts were surrounded made it impossible to take any steps unless the case was clear and conclusive, and those offending against the Acts were so fully aware of their vagueness that in general they had no difficulty in obscuring the issue and of conducting their practice by means of titles which, although bogus, kept them outside the reach of the law The matter of Mr Coroner Troutbeck had continued to engage the attention of the council and numerous complaints had been received as to his action in retaining the services of Dr L Freyberger in a large percentage of inquests to the detriment of the practitioners living in the districts concerned Certain steps were being taken which, it was hoped would put a stop to the course adopted by Mr Troutbeck a course which although not unlawful could certainly be described as not 'expedient either in the interests of the public or of the medical profession Communications had been made both to the Lord Chancellor and to the Prime Minister (Mr Balfour) and also to the London County Council, but inasmuch as the matter at present was so to speak, *sub judice* the council was unable to give more precise details In the report furnished by the solicitor to the union Mr W E Hempson stated that the year s legal work of the union had been a heavy one The total number of cases referred to him and completed within the year was 182 These cases showed that the work of the union extended over the length and breadth of the United Kingdom Of the 182 cases 13 affected members resident in Wales, six related to matters concerning members residing in Scotland, and five had relation to matters dealt with in Ireland Of the remaining 158 cases 96 arose in London and the suburbs and the remaining 62 were distributed over the various provinces in England The useful and beneficial provisions of the Public Authorities Protection Act 1893 so far as they affected medical men placed in official positions were brought out in an action occurring in the past year and which in point of decision had the advantage of having been adjudicated upon by the Court of Appeal Amongst some excellent advice given to members of the union the following was worthy of notice —When a medical man was called in to attend an employé in certain works he generally took it as a matter for granted that his fees would be paid by the employer, he therefore accepted the case and continued to attend When the account was rendered the employer often denied liability altogether or else expressed his willingness to pay for the first attendance only leaving the medical man to look to the patient for the fees for the subsequent treatment In the majority of cases no evidence was forthcoming in support of the medical man s claim for his fees against the employer and the advice was given that when called in in such circumstances a clear understanding should be arrived at in writing if possible as to whom the medical man was to look to for payment of his fees The number of members on the register of the union was 6266 and the amount of the guarantee fund was £8844 17*s* 6*d* After the report had been unanimously adopted, Dr F J Wethered, the honorary treasurer of the union, proposed that the balance sheet of accounts should be adopted He commented on the increase in law expenses but did not regard it as unfavourable because it showed that the union spared no cost in obtaining the very best legal talent available for n
with litigation The
due to the extra expe
British Medical Asso
Members of the union
facts of the case and that cost money —The motion proposed by Dr Wethered was duly seconded and carried unanimously —The proceedings ended with a vote of thanks to the President to Dr A G Bateman, the general secretary, and to Mr Hempson, the solicitor to the union

THE LANCET.

LONDON: SATURDAY, JUNE 3, 1905.

The Protection of our Mercantile Marine from Overcrowding and Disease.

THE last annual report of the medical officer of health of the Port of London suggests many reflections with respect both to the protection of the metropolis from sea-borne exotic diseases and with reference to the sanitary conditions under which the sailor lives when afloat. It is more particularly upon this latter point that we shall now dwell. In connexion, however, with the subject of the introduction of such diseases as plague, cholera, and yellow fever it is necessary to observe that there is too great a tendency in the mind of the public to assume that the river Thames is the only channel along which sea-borne diseases can be conveyed to the metropolis. But without for a moment underrating the value of the admirable work performed by the port sanitary authority of London in this particular, it will be apparent to all those familiar with the broader aspects of the question that London is dependent for its immunity upon practically every port in this country and more particularly upon ports such as Liverpool, Southampton, Bristol, and Plymouth, at all of which places passengers land who within a very few hours become part of this great metropolis. As, therefore, there is no inspection of foreigners or aliens on their arrival by train in London it is obvious that other ports must in some degree share with London the honour of protecting the Londoner from exotic disease. In so far, however, as the metropolis is concerned in its own protection it is eminently satisfactory to find that in the opinion of Dr. HERBERT WILLIAMS, the medical officer of health, "the port sanitary authority is in a position to deal with any possible epidemic with absolute confidence." As, therefore, the year 1904 presented no very remarkable features with reference to exotic disease in this port we shall pass on to consider another question, which is of great importance to seamen generally, and which is dealt with very fully by Dr. WILLIAMS in his current report. Although, in the first instance, our port sanitary authorities were formed to protect us against exotic diseases, and although unfortunately some of our smaller authorities still regard this as their only duty, it is a gratifying fact to find that the larger authorities have duly appreciated their responsibilities with reference to the comfort and the wellbeing of the sailor. It might, indeed, be said that the chief duty of a port sanitary authority during non-epidemic times is to look to the sanitary conditions under which the seaman is compelled to live. No one who has had any experience of life at sea and who is cognisant of the conditions of life in the forecastle will question the utility of this side of the work of port sanitary authorities, and the fact that during 1904 no fewer than 33,493 vessels were inspected in the Port of London will convey some idea of what an important work is being carried out on the Thames in this sense, more especially when it is borne in mind that in nearly 13 per cent. of the vessels visited the cleansing of the crew's quarters resulted from the visit. Of the total number of vessels inspected 84 per cent. were under the English flag.

The conscientious medical officer of health, however, when he inspects a vessel is anxious to do something other than to order the forecastle to be cleansed. He desires above all more cubic space, more ventilation, and more light. But as he leaves the forecastle he turns to an inscription over the door and sees there evidence of the fact that the forecastle has been duly certified by the surveyor to the Board of Trade as fitted to accommodate, presumably *as regards space, light, and ventilation, a certain* number of seamen, and finding that this number is not exceeded he hesitates before suggesting structural alterations. This is practically the mental attitude of every medical officer of health and although a "ship" is, legally speaking, a "house" the medical officer of health soon finds the impracticability of dealing with a house afloat as he would with a house ashore. The fact is that the provisions of the Merchant Shipping Act relating to the cubic space, ventilation, and so on, of crews' quarters are much in need of revision and until something is done in this direction the work of the port medical officer of health will continue to prove discouraging. As Dr. WILLIAMS points out, the amount of cubic space allowed to seamen is far less than that provided for military barracks, workrooms, and common lodging-houses. Indeed, the result of an investigation made on board four vessels constructed between 1899 and 1904 was to show that in one of the vessels, had the forecastle been occupied by the number of persons for which it was certified by the Board of Trade, each occupant would have had some 85 cubic feet of air space and 12 square feet of floor space, whereas on shore anything below 300 cubic feet per head is regarded as overcrowding. It is pointed out, too, that in a room of the size of the forecastle here in question it would be necessary under the London Building Act to provide two windows measuring some four feet by three feet each, the windows in the forecastle measuring only two-thirds of a square foot. Other instances of a similar nature are furnished in the report before us and Dr. WILLIAMS adds that, in these circumstances, it is not surprising to find a large number of cases of tuberculosis among seamen and firemen. It is for this latter class—the firemen—that Dr. WILLIAMS specially pleads since, unlike the seamen, the firemen spend their working hours under the extremely trying conditions of the stoke-hole. All medical men who have acted as ships' surgeons in the tropics or, indeed, anywhere, will cordially agree with Dr. WILLIAMS on this point.

Doubtless the answer of the shipping interests to these criticisms would be to the effect that it is unreasonable to ask for the same minimum at sea as is asked for ashore and reference would be made to the fact that the wealthy classes take voyages for health and pleasure on modern vessels wherein the cubic space in the state-rooms is far less than the same class is accustomed to ashore; far less, probably, than the 300 cubic feet of the common lodging-house. This criticism must obviously be allowed weight and reformers will do well to make the allowance. But it has to be remembered that on modern vessels the ventilation of the cabins is a matter which receives great attention and that the lighting is much superior to anything likely to be found in the forecastle. Moreover, the passengers do not take their meals and spend their spare time in the cabins. They have ample saloon and deck accommodation and work neither in the stokehole nor between decks. But Dr. WILLIAMS goes, we think, straight to the main issue when he points out that the forecastle, where it is obviously impracticable, owing to the cramped position and exposure, to procure either adequate light, space, or ventilation, is not the proper place for crews' quarters. He urges, and there is clearly much to be said for the suggestion, that in steamships the crews' quarters should be aft and in sailing vessels they should be amidships. Dr. WILLIAMS proposes, as a remedy for the present unsatisfactory standards of the Board of Trade—and a similar suggestion was, we believe, made a few years ago by the medical officer of health of Manchester—that the plans of all new vessels should, in so far as the inhabited quarters are concerned, be approved by the local sanitary authority on the lines of model by-laws drawn up by the Local Government Board. There can be no doubt, assuming that the smaller sanitary authorities had the necessary expert advice at their disposal, that advantage would accrue from such a course, although we doubt the reasonableness of pressing for land standards. The conditions under which the sailor lives are slowly improving and if the crews' quarters could be removed to a position where light, space, and ventilation might be easily secured a very material further advance would be made. Perhaps the London port sanitary authority could persuade the President of the Local Government Board to receive a deputation upon the subject or a conference might be arranged between the shipping companies and the port sanitary authorities.

Nutrition and Malnutrition.

THE application to pathological conditions of the results obtained by physiologists in their study of the normal structure and functions of the tissues and organs of the body and of those obtained by cytologists in their study of the manifestations of life in simple organisms has in many cases contributed materially to the elucidation of the problems of disease, and the somewhat trite definition of pathology as "physiology in difficulties" is more than justified. In the special department of neurology the closely associated study of the physiology and pathology of nervous organs has yielded a fruitful harvest to both and the neurologist in nearly all cases is both neuro-physiologist and neuro-pathologist. In other branches of medical work unfortunately the association in the past has been less close, at any rate in this country, and in the study of vital phenomena the physiologist and the physician are apt to look upon one another with some degree of mutual distrust, the physiologist regarding the conclusions of the physician from a study of disease as of necessity too inexact to admit of physiological inferences, the physician, on the other hand, regarding the conclusions of the physiologist as theoretical and inapplicable, and therefore neglecting to keep in touch with recent physiological literature relating to his own sphere of work—a matter, indeed, of great difficulty in these days of numerous publications.

In his Lumleian lectures delivered before the Royal College of Physicians of London and published in our columns[1] Dr. W. H. ALLCHIN has summarised in a masterly fashion some of the problems in the bio-chemistry of nutrition and the present state of our knowledge in regard to them. Dr. ALLCHIN possesses a faculty for concise statement, for lucid exposition, and for critical acumen which have enabled him to condense within the limited compass of three lectures a wealth of information and of suggestive lines of thought for future research. Dr. ALLCHIN has not hesitated to devote two of his three lectures to the study of the normal processes, to the statement of recent work, and to the general trend of physiological opinions at the present time, and has not feared to include controversial matter or suggestive hypotheses, but always clearly indicating how far such views are supported by experimental facts. The method in his hands yields such excellent results that we can only express the hope that other workers in the border regions of physiology, pathology, and therapeutics will follow the lead so suggestively given, the more so that the method after all is the most rational one and serves, moreover, the double purpose of affording to the physician suggestions in his work and of opening out possible new lines of research to physiologists in the elucidation of problems of disordered function. Dr. ALLCHIN defines "nutrition" as "that series of changes which the ingesta undergo in the body to fit them for use by the living matter in the maintenance of its own integrity and as the material from which energy is liberated," and further states that "underlying as it does the characteristic activities of living matter nutrition may in its widest sense be regarded as synonymous with life itself." The material factors of the nutrition problem are "the living matter of unknown and perhaps unknowable exact composition of the chemical nature of which we have any conception from its derivatives only; and, on the other hand, its food which corresponds in great measure to these same derived substances." The essential point of the whole problem is the assimilation of the nutriment or its incorporation into the protoplasmic molecule. A very important point made by Dr. ALLCHIN, the more important seeing that it is often lost sight of in the discussion of the problems of nutrition, is that protoplasm is not of uniform composition even in the same organism and therefore that the nutritive needs of the different constituent cells are not exactly the same. In other words, we may regard each cell as a small factory requiring its raw material in its own special forms to be dealt with in its own special manner. Dr. ALLCHIN illustrates the problem of nutrition by "the conception of a pyramid up the slopes of which the requisite food-stuffs travel with ever-increasing complexity of composition until when the summit is reached the molecule topples over, as it were, from sheer instability, to pursue its descent towards those simpler atom-groups which we recognise as waste products, liberating in its progress that energy which it had accumulated in the process of its synthesis." He points out, however, that we must recognise that the two processes of anabolism and katabolism are not to be regarded necessarily as a sequence, but rather as coincident and perhaps even mutually determined, and since energy is used up in anabolic operations that the actual energy necessary has to be furnished by coincident katabolic changes in the cell. The chemical changes involved in many of these processes are such as can be more or less successfully imitated by laboratory methods, but always by high temperatures or strong chemical reagents or powerful electric currents which would inevitably destroy the life of the cell; whereas in "the simplest living cell these changes are effected rapidly and surely without any such powerful agencies." The manner in which these changes occur in the cell according to recent research seems to be in nearly every case by the action of enzymes or chemical ferments, themselves the product of the living cells, even the processes of oxidation and perhaps reduction being apparently brought about by ferments such as the "oxidases." In other words, the study of the nutrition problem resolves itself largely into the study of certain special ferment actions and the conditions favouring or hindering these actions; and although this is unfortunately far from the actual solution of the problem owing to our lack of knowledge of the nature and mode of action of these ferments yet it somewhat simplifies the problems by indicating lines of research. Dr. ALLCHIN gives a very comprehensive account of the ordinary digestive ferments, including their wonderful adaptation to the purpose for which they are required and their interdependence, discussing also the rôle played in these processes by secretin and enterokinase. He further discusses the existence of proteolytic ferments and of "erepsin" in the tissues themselves as possibly serving to effect that transference of proteid from one tissue to another which undoubtedly occurs in starvation. The section of the second lecture summarising the views held with regard to the rôle of ferments in nutrition is of particular interest and contains a statement of the views of CROFT HILL on the reversibility of ferment action, showing that the older views of ferments as always katabolic in tendency must be modified and their power of effecting synthesis must be admitted.

---

[1] THE LANCET, April 29th, May 6th, 13th, and 20th.

The relation of the nervous system to nutritive processes is also discussed and Professor LOEB'S interesting experiments on the relations of "ions" to vital activity and nutrition are referred to as possible factors of importance in determining intracellular fermentation and its phases. The third and last lecture, in which the views enunciated and elaborated in the first two are applied to the study of conditions of malnutrition, is of especial interest and importance. The problems discussed are necessarily of great complexity, varying from the comparatively simple case of starvation, which can be readily investigated, to the difficult problem of perverted metabolism in cachexias, or as a result of the action of toxines. The effects of an excessive diet, or of diets wrongly constructed, are also discussed, as are the effects on nutrition of maldigestion and malabsorption. Dr. ALLCHIN points out that deficiences in the quality and quantity of the food and disorders of the digestive processes may occur without the production of any degree of malnutrition and that it is not until the essential factor of nutrition —i.e., ferment action—is involved that actual malnutrition supervenes and that, therefore, the chief conditions leading to malnutrition are those which hinder or modify the normal ferment actions. The results of a deficient supply of oxygen or inability to use it are next described and the deficient oxidation and "air hunger" of the diabetic in the state of coma are referred to the incapacity of the tissues to make use of the oxygen supplied to them. The lecture concludes with a brief study of atrophy, degeneration, and death, and Dr. ALLCHIN infers from a study of LOEB'S researches that "if, then, it is possible by the application of certain electrolytes to avert from a living ovum what may be termed its natural death, similarly to avert the degeneration and death of the tissue cells of higher organisms may be looked upon no longer as a hopeless quest."

◆

The Spread of Small-pox occasioned by Small-pox Hospitals.

CONSIDERABLE attention is just now being directed to the effect of small-pox hospitals in increasing the prevalence of the disease among susceptible people living in their neighbourhood during epidemic periods. The subject is of considerable importance in view of the necessity of small-pox hospitals to control the spread of this disease in the present state of our vaccination law. Its study is by no means easy and requires collection and comparison of a mass of statistical and other data scattered through a variety of public health reports and official blue-books. A valuable series of recent reports issued in connexion with the prevalence of small-pox during the past few years, together with the discussions which have lately taken place at the Newcastle meeting of the Royal Sanitary Institute and at the Epidemiological Society of London, enables us, however, to bring together some of the main considerations which arise. Much new light has been thrown on the question of the carriage of small-pox infection by means of aerial convection currents but with this large subject we are unable to deal in the compass of the present article. Here we desire to draw attention to the most conspicuous feature of the reports and discussions to which we have referred, namely, the almost unanimous testimony to the reality and the importance of what is termed "hospital influence" in epidemics in which the small-pox hospital has been situated within a town or in some other position in which it has had a considerable populous area in its vicinity. Fortunately at the present day it is comparatively rare for small-pox hospitals to be thus placed. The experience of London before all small-pox cases were removed down the river as a result of Mr. W. H. POWER'S classical inquiries has become a matter of history. This experience, together with the numerous instances of a similar kind which have since been reported, has led in many cases to separation of hospitals intended for small-pox from those utilised for other infectious diseases and to the selection for the former class of hospitals of sites which lie in sparsely populated districts. During the past five years, however, several places which have been attacked by epidemic small-pox have depended for isolation on hospitals which have had considerable collections of dwellings close to them. In several of these places the facts as to the local incidence of small-pox have been ascertained by careful and minute inquiries which leave no doubt of the marked effect which the hospitals in question have exerted on people living in their neighbourhoods. In 1901 there was the well-known instance of the small-pox hospital ships in Long Reach and their effect upon the prevalence of small-pox in Purfleet and in other places on the northern bank of the Thames opposite the ships, reported first by Dr. J. C. THRESH and later by Dr. G. S. BUCHANAN. In 1902–03 occurred the severe epidemic of small-pox in Liverpool, the relation of which to the three small-pox hospitals of the city is dealt with in Dr. R. J. REECE's report to the Local Government Board referred to in THE LANCET of May 27th, p. 1456. The epidemic of small-pox which affected Gateshead and the adjoining district of Felling in 1903–04 was shown by Dr. BUCHANAN and by Dr. T. E. HILL to have been increased to a considerable extent by the persistent and excessive incidence of the disease round the Sheriff-hill Hospital which was used for the isolation of the Gateshead cases. Dr. A. K. CHALMERS has furnished a remarkable series of data showing that during the successive epidemics which have occurred in Glasgow between 1900 and 1904 it happened on each occasion that in whatever part of the town small-pox originated it sooner or later became concentrated in the eastern corner of the city in the areas which are in closest proximity to the municipal hospital at Belvidere. After making every allowance for reported negative instances (such, for example, as the escape of institutions near the Edinburgh small-pox hospital described by Dr. C. B. KER to the Epidemiological Society) the fact remains that recent experience not only has illustrated the frequency with which "hospital influence" has been traced where the conditions permitted but also has emphasised its practical importance and the necessity for its prevention. The "*standards*" which have been laid down by the Local Government Board regarding limits of population in the vicinity of a small-pox hospital have *often* been criticised. They are open to the objections *common to most* standards; in some instances, as last year in what is called the Nottingham case, they have been opposed on the ground that they do not provide sufficient security, while in other cases, especially where small hospitals are in question or where the population near the hospital is concentrated in one or two institutions, it has been urged with some force that to insist upon strict compliance with the standards is needlessly vexatious and entails an amount of administrative inconvenience disproportionate to the risk which it is desired to minimise. But however this *may be*, *it can hardly* be disputed that in their broad result of securing that the majority of small-pox hospitals in the country have been placed away from important centres of population the official regulations have gone far to remove one of the most important agencies by which epidemic small-pox may be spread and maintained.

HOSPITAL FOR SICK CHILDREN.—Before Mrs. Choate, the wife of the retiring American Ambassador, sailed for the United States on Tuesday, she sent a donation of £20 to the Hospital for Sick Children, Great Ormond-street, in which institution Her Excellency was much interested, as a parting gift.

Annotations.

"Ne quid nimis"

THE TENURE OF PUBLIC HEALTH APPOINTMENTS.

IN THE LANCET of *April 29th* we commented upon the very *unsatisfactory state* of matters existing in the Chipping Sodbury rural district with *regard to its medical* officer of health. To recapitulate, Chipping Sodbury has ever since *1873 acted* in concert with several other district councils of Gloucestershire by appointing a joint medical officer of health and that officer since 1873 has been Dr. F. T. Bond, who since *1868 has been annually re-elected by the individual councils. In October, 1904,* three new parishes were added to the Chipping Sodbury district and *the council* of that district requested Dr. Bond to undertake the *control* of these additional parishes without any extra remuneration. Dr. Bond naturally enough demurred at doing this and eventually he was granted an increase in salary of £33 *per annum. When the time* for his re-election came the Chipping Sodbury rural district *council refused* to re-elect him and appointed a local practitioner. The council *further* desires to withdraw from the combination of councils and applied accordingly to the Local Government Board to sanction the appointment of its nominee but the Local Government Board has not done so. An inquiry, *on the* contrary, was *held* by the Board and as a result the following letter has been addressed by the Board to the constituent councils of the districts.—

(COPY.)

u seeing that the late
ted as clerk to the old
uld feel obliged if you
he several constituent

. Assistant Secretary.

We have not yet heard whether the members of the Chipping Sodbury rural *district council* have *accepted the invitation* to confer with the representatives of the other councils in the combination but we congratulate the Local Government Board on its action. It is, we fancy, a new departure for that Board to attempt to bring a recalcitrant district council under the influence of the public opinion of its neighbours. If the Chipping Sodbury rural district council persists in withdrawing from the combination and in appointing its own medical man without the sanction of the Local Government Board his salary will have to be paid in full by that council instead of one-half being provided by the county council. But the action of the Chipping Sodbury rural district council is a good *object lesson in* the *uncertainty of* tenure which medical officers of health suffer. No complaint was brought against Dr. Bond of neglect of his duties and apparently the sole reason for his dismissal by Chipping

Sodbury was his refusal to look after the health of the three added parishes for nothing. The conference of councils is summoned for June 19th.

POISONOUS HONEY.

POISONING by honey has been known since the days of Xenophon, when it seems to have been fairly common, and has been observed in various parts of the world—Germany, Switzerland, North and South America, India, and New Zealand. In the *New Zealand Medical Journal* for April Dr. E. D. Aubin has published an important paper on cases of poisoning due to wild honey, which were observed most frequently in Maoris. As the poison evidently is derived from plants visited by the bees its nature varies in different countries and so do the symptoms. In New Zealand only wild honey appears to cause poisoning. The symptoms usually followed ingestion of the honey in less than an hour. Three modes of onset were observed which Dr. Aubin terms respectively gastric, nervous, and cerebral. In the gastric form giddiness and nausea are followed by severe and persistent vomiting which may last on and off for two days. There is usually some abdominal pain but this is not as a rule a prominent symptom. The mouth feels dry and glazed. Apparently no irritant action is exerted on the bowel for diarrhœa was never observed. In the second mode of onset Dr. Aubin attributes the symptoms to irritation of the peripheral nerves, which is indicated by tenderness in the muscles; pains, chiefly of a burning character, in the muscles of the arms, the legs, the back, and the abdomen; itching; and a feeling of "pins and needles" or numbness in the arms and the legs. Such symptoms are observed in the early stages of peripheral neuritis and in poisoning by mussels. In the third mode of onset cerebral symptoms occur. For example, a Maori who had partaken largely of honey suddenly dropped down in a fit. He became unconscious and fits recurred at intervals. Delirium may be the first symptom. In severe cases, as a rule, the gastric, nervous, and cerebral symptoms are combined, one set of symptoms predominating. The characteristic symptom of poisoning by honey as observed in New Zealand is the epileptiform fit. This, as stated, may mark the onset or may not occur for an hour or more. It differs in no way from an ordinary epileptic fit and may be preceded by a cry. The head is jerked to one side with conjugate deviation of the eyes and tonic and clonic spasms occur. Cyanosis and frothing at the mouth are present and the tongue may be bitten badly. After the fit the patient may be quiet and may sleep or may be restless and delirious. In severe cases the patient is unconscious between the fits which usually recur several times. In some cases the convulsions may be more or less continuous and may result in death. The fits generally cease in less than 24 hours. Slight vaso-motor phenomena are usually present, the face and the skin generally feeling hot and swollen. Urticaria was never observed. The duration of the illness is from a few hours to two days, though nervous symptoms are sometimes complained of for a considerable time afterwards. In fatal cases death usually occurs within 24 hours. The symptoms, no doubt, are due to a poison in the honey, probably of the nature of an alkaloid which affects chiefly, if not wholly, the nervous system. The gastric symptoms, Dr. Aubin thinks, are of cerebral origin—a view which is supported by the absence of signs of intestinal irritation. We may add that in other countries such signs have been observed. As to the source of the poison, Mr. Hopkins, Government apiarist, thinks that it comes from the yellow flowers of a cress-like plant called the "whauriki" which grows chiefly in swamps. In other countries a species of rhododendron has been suspected. Wild honey found near the New Zealand swamps is especially liable to be poisonous. The most remarkable feature of the symptoms is the epileptiform fits—a condition unknown in acute poisoning due to any other cause, though well recognised in chronic plumbism. With regard to treatment Dr. Aubin recommends the administration of an emetic if vomiting has not occurred and washing out of the stomach in all cases. Potassium bromide should be given in full doses. A dose of calomel followed by an enema is also beneficial. As a rule stimulants are not advisable but may be given if the heart is failing. In cases of continuous fits bleeding and saline injections are indicated.

CENTENARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT the premises of the Royal Medical and Chirurgical Society there was on view during the celebration of the centenary of the society an interesting exhibition of books, instruments, and other objects brought together mainly for the purpose of illustrating the condition of medicine at the time when the society was established. The exhibition contained objects in connexion with the early history of the Royal Medical and Chirurgical Society and in addition it included memorials of various kinds relating to the presidents of the society. There were also exhibited some of the medals which had been struck to honour or to commemorate Fellows of the society. The exhibits were arranged in six sections. The first section contained books and was subdivided into three parts, the first part being that of books in use by the society in the year of its foundation, 1805. The second part comprised books and pamphlets on vaccination, including a Chinese work printed in the tenth year of the Emperor Kea Kong (1805) with an English translation by Sir George Macartney sent as a present to Dr. Jenner. The third part contained a few miscellaneous books amongst which was a Pharmacopœia of St. Bartholomew's Hospital printed in 1799 by J. Adlard and lent by Mr. R. E. Adlard. The second section contained manuscripts. Amongst these was a list of the so-called African surgeons who were persons who had passed an examination in medicine and surgery at the Liverpool Royal Infirmary and were considered competent to act as surgeons on vessels engaged in the slave trade. There was also a letter complaining that other bodies had certified candidates who had been rejected by the Liverpool Royal Infirmary, many of whom were not only destitute of medical and surgical information of every kind but also of every other species of information. The third section comprised instruments and amongst these the midwifery forceps which belonged to Dr. John Burton, the prototype of Dr. Slop in "Tristram Shandy," who in Chapter XIX. is thus referred to: "Of all men in the world, Dr. Slop was the fittest for my father's purpose; for his newly-invented forceps was the armour he had proved to be the safest instrument in deliverance." The fourth section was made up of portraits and the fifth section of medals. The sixth section was labeled Miscellaneous and contained some curious pictures; one was that of the birth of Parikshit of the family of Krishna. The child was born dead but was restored to life by Krishna. On the left of the picture the mother is depicted in the birth chamber undergoing the treatment which has been customary for many ages in India. It is always a good thing for the members of any profession to look backwards as well as forwards and it is more important for the medical profession than perhaps for any other. Not only do we profit by what we know to have been the mistakes of our ancestors, but we learn the valuable lesson that in many matters we do not know much more than they did. Some little time ago an American physician, Dr. Eugene F. Cordell, delivered an interesting address before the Medical and Chirurgical Faculty of the State of

Maryland in which he lamented the lack of the teaching of medical history in the universities of that State. He pointed out that the study of medical history taught us what and how to investigate, that it increased knowledge and strengthened the judgment, that it was a mine from which many neglected or overlooked discoveries might be brought to light, and that it taught us to cherish our best traditions. With these opinions we thoroughly agree and we congratulate the Royal Medical and Chirurgical Society upon having made a historical retrospect a part of its centenary celebration.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND: ELECTION OF MEMBERS OF COUNCIL.

AT the annual meeting of Fellows on the first Thursday in July there will be elected four Members of Council. Three of these vacancies will be occasioned by the retirement in rotation of Sir Henry Greenway Howse, Mr. Edmund Owen, and Mr. Rickman J. Godlee; the fourth vacancy will be due to the resignation of Sir Alfred Cooper. We understand that Mr. Owen and Mr. Godlee will offer themselves for re-election but that Sir Henry Howse will not stand again. Mr. C. H. Golding-Bird, surgeon to Guy's Hospital, announces his intention of standing for one of the vacancies and Mr. Harrison Cripps, surgeon to St. Bartholomew's Hospital, also proposes to be a candidate.

REPEATED COPIOUS HÆMOPTYSIS FROM AN AORTIC ANEURYSM.

To the general rule that rupture of an aortic aneurysm is immediately fatal rare exceptions have been recorded. One was recently published in our columns by Dr. C. H. Melland.[1] Usually one or two severe hæmorrhages have been followed by months or years of exemption. In the *Johns Hopkins Hospital Bulletin* for March Dr. T. W. Clarke has reported a case which appears to be unique in the occurrence of a series of large hæmorrhages. A man, aged 39 years, came into hospital, under the care of Dr. E. F. Cushing, on July 13th, 1904, complaining of pain in the right upper chest, cough, and hæmoptysis. There was a history of gonorrhœa and soft chancre but not of syphilis. The patient dated his present illness from a year before admission, when he began to have discomfort in his chest, especially on the right side, dyspnœa, dizziness, tinnitus, and attacks of weakness. His general condition became worse until two weeks before admission when he began to cough and to expectorate small quantities of blood. The pain in the chest grew more severe and on admission extended to the right shoulder and down the right arm to the elbow. On the day of admission profuse hæmorrhage occurred. On examination he was found to be a muscular man, coughing frequently and expectorating considerable quantities of blood-stained mucus. The voice was husky but not "brassy." The left pulse seemed slightly fuller than the right. There was a slight tracheal tug. In the first, second, and third right intercostal spaces there was visible pulsation but no bulging. Over the pulsating area a slight systolic impulse, followed by a diastolic impact, was felt and dulness was obtained. In the back dulness extended from three centimetres above the angle of the right scapula upwards for eight centimetres. Over the right upper chest were heard a diastolic shock and a loud friction rub synchronous with the respiration. *Aortic aneurysm* was diagnosed and a modified form of Tufnell's treatment was ordered but the patient objected so much that the attempt had to be abandoned. After the second day the bleeding stopped and the cough and pain were greatly relieved, but on July 23rd four ounces of almost pure blood were expectorated. This was the beginning of a remarkable series of 16 hæmorrhages. The others took place as follows: July 29th, 8 ounces; August 2nd, 12 ounces; 6th, 32 ounces; 9th, 16 ounces; 11th, 36 ounces; 17th, 16 ounces; 20th, 6 ounces; 21st, 20 ounces; 24th, 28 ounces; 28th, 10 ounces; Sept. 2nd, 4 ounces; 3rd, 2 ounces; 5th, 16 ounces; 13th, 8 ounces; and 14th, 7 ounces. This makes in a period of seven and a half weeks over 14 pints of almost pure blood. The hæmorrhages came on after some exertion, such as sitting up or reaching for an article on the floor, lasted only a few minutes, and were accompanied by paroxysms of coughing. They were stopped by the administration of morphine, as much as a grain being sometimes required. The patient became steadily paler and in the first month the red corpuscles fell from 4,864,000 to 2,304,000 and the hæmoglobin from 65 to 38 per cent. On Sept. 15th, during a fit of anger, the patient sat up in bed, became very weak, broke out into a cold sweat, and said he was dying. He died in about 20 minutes. During the last few days of life there were signs of fluid in the right chest. At the necropsy 3000 cubic centimetres of dark blood-tinged fluid and flakes of fibrin were found in the right pleural cavity. The aorta throughout was the seat of a number of large and small irregular thickened areas which projected slightly into the lumen. On the right side three centimetres above the valves was an oval opening 2·5 by 1 centimetre in diameter leading into a spherical sac nine centimetres in diameter filled with laminated fibrin. The sac was covered by, and adherent to, the pericardium and visceral pleura, but at one point there was a tear five centimetres long communicating with the pleural cavity. Small bronchi could be traced into the sac but no blood was found in the air passages. The repeated hæmoptysis was evidently due to these small communications which ordinarily were plugged by fibrin. On exertion the fibrin no doubt shifted, giving rise to hæmorrhage.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

IN the interesting address which appears in another column Dr. Lucas-Championnière sets very plainly before our readers the differences between the course of medical study as it exists in France and in our own islands. Shortly, he says, the differences may be expressed thus. In Great Britain individual effort is everywhere free and encouraged; in France the municipality or the State hinders the development of individual effort. In the former land institutions are autonomous; in the latter centralisation reigns supreme. In France the pupils at secondary schools are closely supervised; in Great Britain the boys at public schools have but little supervision. But when a French scholar enters upon his career as a medical student he becomes practically his own master. Attached to the Paris Faculty of Medicine are some *6000 students* any one of whom can work just as much or as little as he likes. *He is not tied to one hospital* but can attend at any or all of the Paris hospitals and he follows the teaching of any member of the staff of the hospitals as he pleases. In Great Britain the student is practically tied to one hospital and is a pupil of the staff of that particular institution; nay, more, during a portion of his career he is definitely attached to one particular member of that staff. In Great Britain the hospitals are autonomous institutions, while in France they are municipal or Government institutions. In Paris they are all under the Assistance Publique, an organisation which may be roughly compared with our boards of guardians, Local Government Board, and Metropolitan Asylums Board. All the Paris hospitals are under its control, as well as nearly all other charitable institutions. Its annual budget amounts to 45,000,000 francs and it obtains its funds from certain endowments, from sundry taxes which it has the right to levy, and from a sum voted annually by the city of Paris. Owing to anyone who is poor and in want having a right to hospital accommodation the Paris hospitals are often much overcrowded. No one is better aware of the unavoidable shortcomings of the Paris system of hospital and poor relief than the Paris medical men themselves, but, taken as a whole, the Assistance Publique does admirable work. Dr. Lucas-Championnière's address deserves careful study and we may say that the methods which each nation employs are those best suited to the genius of that nation, but, on the other hand, that the intercommunication which has so recently taken place between the members of the medical professions of France and Great Britain will lead to each nation respectively becoming aware that it may learn to supply its deficiencies from the practice of the other.

---

[1] THE LANCET, Nov. 19th, 1904, p. 1414.

SOME ODD FOODS.

COMPLAINT is often made that the average daily meal in the ordinary household is a monotonous round of mutton and beef. In the majority of instances this simple and oftentimes uninteresting cycle of food is compelled on the score of convenience and economy, although with a little more thought and trouble than are usually bestowed on this matter we are convinced that more variation could be contrived. The subject deserves greater attention than it has hitherto received and the results in all probability would be pleasing. In this connexion it is interesting to consider some of the more or less odd materials which man has been led to choose for the purposes of food. Environment, of course, must be a factor in regard to this choice, and necessity also. It is hard to imagine that earth would be used for choice as food and yet such has been the case in many countries during famine. The Laplanders mix earth with their bread, the Russian peasant uses a "rock flour," and the poorer classes in Hungary are driven occasionally to eat an earth which contains but a trifling proportion of nourishing principles. The use of seaweed as food is an example of the determining factors of both necessity and environment. It is not a little astonishing to find what a number of seaweeds are really edible and nourishing. Perhaps the best-known example in this country is laver, which is a kind of stew made from a weed, an alga (porphyra laciniata). The laver made on the Devonshire coast and to be found in some London shops is excellent. The sea algæ, indeed, prove on analysis to contain a considerable proportion of nitrogenous matter and as they are usually tender they are digestible. There are also several sea mosses which are esteemed for their esculent properties. Agar-agar is another example of a seaweed yielding a nutrient jelly. It is supposed that the edible birds' nest so highly esteemed when prepared in the form of soup by the Chinese has its origin in the birds feeding upon agar-agar. On the other hand, it is said that the substance of which the nest is composed is secreted from certain glands which are developed during the nest-building season but which lose this function afterwards. The viscid substance resembles the mucin or albumin excreted by the sublingual gland. The turtle may be regarded as an odd article of food since it is the only example of an edible reptile, at least, in this country. Frogs' legs, again, are rarely eaten in this country, though they are easily digested, possess a delicate flavour, and have about the same nutritive value as chicken. Neither is the snail esteemed as an article of food in this country, though in France it is partaken of in large quantities and so good is it that it has been called "the poor man's oyster." The edible snail, however, is a particular kind and is generally collected in considerable number from the vineyards in the south of France. In Spain the snail is served in a most excellent and appetising manner, and in Paris a dish of selected snails is reserved for the special use of the *gourmet*. Coal would appear to be a strange article of food, but instances are known in which children and cats have been found consuming it in a not negligible quantity. There is no evidence, however, although coal contains an abundance of one of the most important elements of food—i.e., carbon—that in this form it is in the least degree assimilated. It is almost impossible to oxidise by wet methods carbon in the free state, whereas in combination with other elements, and especially hydrogen, as in the carbohydrates, wet combustion in the economy readily ensues. Such instances of odd foods could be multiplied but those quoted serve to show the extraordinary range of material selected by man for the purposes of food.

CRICKET, HEALTH, AND ANATOMY.

WE have received from the Fine Art Society Parts I. and II. of a clever series of portraits which the society is publishing, publication commencing, appropriately enough, in the week when the first match between England and Australia has been brought to a victorious conclusion for the mother country. The work is entitled "The Empire's Cricketers"[1] and conspicuous among the portraits in the first two instalments is that of a medical man whose name is probably as well known to the public as that of any member of our profession. Dr. W. G. Grace (we may accord him the title of "Dr." in deference to public usage without any reluctance as he is no longer, we believe, in practice) may not now be chosen to represent England in a "test" match, but his cricket career is by no means run. Mr. Chevallier Tayler, the artist responsible for the portraits in the series, has caught "W. G." in a characteristic attitude awaiting the ball already on its way towards him, and prepared to come down on it in the resolute fashion that means a boundary hit all along the grass—or should we say "carpet"? We must not, however, be betrayed into the appalling lingo of the cricket journalist. Nor, indeed, is it exactly within our scope to comment upon the very clever illustrations further than to say that even those who are least acquainted with the performances of the selected athletes will find it interesting to examine the various studies of physical vigour and trained muscular effort which accompany the portrait of Dr. Grace. Cricket is a game of so manly a character, and is so essentially English in its origin and development, that many will watch with interest the struggles between the picked teams which will take place during the present season, even if in less enthusiastic moments they may deprecate an unreasonable absorption in the study of a game, may regret that young men should postpone taking up the more serious duties of life in order to prolong their indulgence in it, and may regard with impatience the support by counties of teams consisting almost entirely of paid "players." If, however, such a publication as that under review encourages the young to develop their physical powers by healthy exercise, and to appreciate the fact that temperate habits and careful training of eye and muscle are necessary in order to produce good results where eye and muscle have to be used, it is sure to exercise a useful influence. The mere worship of physical excellence by the curious and lazy is the dangerous extreme which is to be avoided. The excellent reproductions of Mr. Chevallier Tayler's drawings are apparently from originals in coloured chalk upon brown paper and the artist evinces considerable skill in depicting the human frame in vigorous action Medical men should appreciate drawings of the human frame by one who makes his subjects men of bone and muscle, not mere models in flannel And as members of the medical profession of all others have to abandon so exacting a game as cricket early, and can find but little time for looking on at it, they will not be sorry to gain some acquaintance with the physical attributes of modern players of note and of methods of attack and defence now in vogue We may suggest that a good lecture in applied anatomy might be founded upon the pictures If the actions of (say) Rhodes at the moment of delivering the ball, or Tyldesley at the moment of late cutting it were used as examples of muscular effort and function we have an idea that the lessons inculcated would stay by the student

THE ROYAL SANITARY INSTITUTE

ON Friday, June 16th, at 4 30 P M , a discussion will be opened at the Parkes Museum, Margaret street, London, W , by Mr Edwin T Hall, F R I B A , on Sanatoria for Consumption Design and Location Among the speakers who have already signified their intention of being present are Mr H Percy Adams, F R I B A , Mr T W Aldwinckle, F R I B A , Mr T W Cutler, F R I B A , Dr C E Reinhardt, Mr A C Scovell (chairman of the Metropolitan Asylums Board), Dr J E Squire, Dr F R Walters, and Dr C Theodore Williams Major General the Right Hon Lord Cheylesmore will preside Tickets for the admission of visitors who are invited to take part in the discussion, may be obtained from the secretary On the following day a visit will be made to the Heatherside Sanatorium, Frimley, the country branch of the Brompton Hospital, conducted by Mr E T Hall, the architect of the sanatorium Luncheon will be provided for members of the institute and special arrangements have been made by which return tickets can be obtained at reduced rates, a first class ticket costing 7*s* 4*d* , a second class 4*s* 7*d* , and a third class 3*s* 8*d* Frimley is distant about two and a half miles from Camberley, the nearest railway station, but conveyances will be provided for visitors at the cost of 3*s* each person The train will leave Waterloo for Camberley at 11 50 A M There are three return trains at intervals of about an hour, the first arriving at Waterloo at 6 55 P M Application for tickets should be made to the secretary of the institute

TRACHOMA AMONG ALIENS

AN important report has just been issued by Dr A K Chalmers, the medical officer of health of Glasgow, upon cases of trachoma which have been treated in the ophthalmic dispensaries of the city and the subjects of which have been aliens These aliens are described as consisting of two or more classes, distinguished from each other by the intended duration of their stay in Scotland At one end is the alien who is also a transmigrant, Glasgow being only a stage in his journey , at the other is the alien who, for a variable period, has become incorporated with the industrial life of the West of Scotland, chiefly as an iron or coal worker, but who in time offers himself at one of the emigration offices for shipment to America It is further said that the medical inspection of emigrants at the original port of embarkation on the Continent is stringent for the direct transmigrant and quite illusory for those who book only to a port in this country Dr Chalmers does not treat the question very seriously, saying that "in its earlier stages trachoma is easily amenable to treatment," that it is not "a disease of fulminating activity," and that "the introduction of a few cases into a district is not, without certain conditions, sufficient to insure a wide extension of the malady " These statements, in view of the past history of the disease, and of its epidemic prevalencies from time to time can only be accepted with much reserve Like many other maladies trachoma probably *confers a certain degree of immunity* upon populations among which its milder forms have long been frequent, but, under certain conditions, it assumes terrible activity, and we have no precise knowledge of what these conditions are It was first introduced into Europe by the army of the first Napoleon on its return from Egypt, and it raged as a veritable pestilence, destroying the sight of a very large proportion of those who were attacked It next made its way into Ireland where it produced equally disastrous consequences Of late years, in England, it has chiefly been known in workhouse schools and from these it has only been eradicated by infinite trouble It is quite conceivable that the secretion of the trachoma which is brought into this country by aliens may be more virulent than that of the home grown disease and that *the importation, after a period of smouldering, may* assume a very formidable character It should, we think, be an instruction to the port authorities under the expected Aliens Act that all persons suffering from the disease should be refused permission to land and that information as to the prohibition should be widely circulated

THE ASYLUM WORKERS' ASSOCIATION

THIS association was founded for the benefit of the rank and file of asylum workers, in whose interests a large amount of honorary work is done by medical men and others concerned with the care of the insane From correspondence in the *Asylum News* which is the journal of the association, and from the annual report of the latter for 1904 it is clear that those concerned with nursing amongst the insane are alive to the importance of safeguarding their interests in the matter of the State registration of nurses, which is at present engaging the attention of a select committee of the House of Commons The association is in this matter cooperating with the Medico Psychological Association, which as the body responsible for the certification of mental nurses may be trusted to take adequate measures to protect the interests of the holders of its certificates We gather from the report referred to that the case of the mental nurse is kept in view in one of the Bills before Parliament on the subject of State registration In this, the eighth annual report the executive committee is able to notify a satisfactory condition of the finances of the association, but it is nevertheless the case that the roll of ordinary members, which is composed of the rank and file of asylum workers, shows a falling off of no less than 486 from the numbers in 1903 The roll now stands at 2910 It is not unlikely that local considerations at the various asylums such as will suggest themselves to those acquainted with these institutions are responsible for considerable fluctuations from time to time in the numbers of an association such as this The report notes the improbability of legislation comprising the settlement of the question of pensions in public asylums during the life of the present Parliament There are, in fact, no signs that the power vested in, and the latitude allowed to, asylum committees and their parent councils in England and Wales in the matter of superannuation of their employés will be in any way modified by the central authority The present conditions do not make for united action on the part of asylum workers on this question, for whereas some have cause to be satisfied with their prospects and would probably deprecate alteration others, possibly their neighbours in an adjoining county, are confronted with a deplorable uncertainty in the matter of superannuation, and even in some instances are aware that they will receive no pension The report further states that attention is being given by the executive committee to the matter of provision of facilities for the training of male attendants in the details of general hospital nursing. The case of the female attendants is not mentioned, from which it might be inferred that they are not in need, or not in equal need, of such training. We do not know, however, that this inference would be at all a sound one in respect of the bulk of asylums in the kingdom.

BARNWOOD HOUSE HOSPITAL FOR THE INSANE, NEAR GLOUCESTER.

FROM the forty-fifth annual report for the year 1904 of the medical superintendent, Dr. J. Greig Soutar, it appears that the average number of patients resident during the year was 146, the admissions were 38, and 18 were discharged recovered (47·3 per cent. on the admissions, but if transfers from other institutions are excluded, as is usually done, 64·2 per cent. on the admissions). Only four deaths occurred. Family predisposition to mental disease was ascertained in 55 per cent. of the admissions. Dr. Soutar states that whereas some years ago the majority of the recent cases were of the maniacal type, acute melancholia is now the prevailing form of disorder and has been of late years. He is unable to suggest any explanation for this change in type. The report of the committee refers to charitable work done by the institution during the year, five patients having been maintained gratuitously and 66 for payments below the average cost of maintenance. It is found that most patients prefer the hospital itself, with its occupations, amusements, and interests, to the separate houses which are also provided, in which experience this institution is not alone. The Commissioners in Lunacy report that this hospital discharges its curative functions with great efficiency.

PHYSICAL EDUCATION.

IN THE LANCET of August 13th, 1904 (p. 487), we published a letter from Sir Lauder Brunton announcing a proposed national league for physical education. The inception of the league practically dates back to July 20th, 1903, when a number of medical men and others interested in the matter were present at a dinner given at the Athenæum Club to discuss the question. The movement has now advanced to the point of being made the subject of a Mansion House meeting at which the matter will be brought more prominently before the public than has hitherto been the case. The meeting will be held at the Mansion House, under the presidency of the Lord Mayor, on June 28th, at 4.15 P.M., for the purpose of inaugurating this association. The following have promised to speak: the Bishop of Ripon, the Lord Chief Justice, Sir William Broadbent, Bart., Sir James Crichton-Browne, Mrs. Bramwell Booth, Alderman and Sheriff Strong, and Mr. J. Compton Rickett, M.P. The objects of this movement may be summed up as—

1. The stimulating of public interest in the various societies which make the improvement of the physical condition of the people their special care.
2. The bringing into close association, and if possible the *federation*, of such societies, so that they may have increased strength, financial and otherwise.
3. The encouragement of and the advising of societies which find it difficult to hold their own under present conditions.
4. Assistance towards the starting of organisations for the benefit of physical health and well-being in remote or poor districts.

The movement has received such general promises of support from all orders, professions, and institutions, and from distinguished men and women of science, medicine, education, and law, and also from individual peers, Members of Parliament, athletes, and others, that there is no doubt that it will supply a great need and will enable much more forcible work to be done in regard to physical well-being than has been possible up to the present. The organising secretary *pro tem.* is Lieutenant-Colonel V. Mellor (Twentieth Century League), 28, Victoria-street, London, S.W. The official title of the movement has not yet been finally decided upon, but it is hoped to announce it a day or two after the Mansion House meeting. The meeting on June 28th will be only of a preliminary nature and we believe that another will be held shortly afterwards.

PASTEUR AND LISTER.

IN the *Echo de Paris* of May 15th there appears an interesting article by Dr. Raoul Blondel upon Pasteur and Lister. After referring to British science and remarking how this country does not, as do some other countries, subordinate science to commercial necessities, he goes on to say that the Briton has respect for science and that this is all the more meritorious of him seeing that in other respects he is by no means a bad man of business. Thus the scientific union between England and France is rendered easy. England practically gave to the world two great discoveries—chloroform and antisepsis; but both of these were in a measure French discoveries before their application by Britons. Soubeiran discovered chloroform in 1831, independently of, though almost simultaneously with, Liebig, although Simpson was the first to employ it in surgery, and no one is more ready than Lister to allow that it was the researches of Pasteur which first led him to evolve the theory of antisepsis and asepsis. Even these two great men had their predecessors. Davaine and Bassi had discovered the bacteriology of anthrax and that of silkworm disease before Pasteur, while Guerin had employed dressings of cotton-wool to filter the air; moreover, Lemaire, Maissonneuve, and others had directed attention to the antiseptic qualities of carbolic acid before Lister. But it was Pasteur and Lister who, by patient work founded on their own labours and those of others, built up an enduring edifice. Their two names will live for ever together and to them may well be applied the saying of Buffon: "Le genie n'est qu'une longue patience.'

A PLEA FOR THE MORE GENERAL USE OF TUBERCULIN.

THE subject of the treatment of tuberculosis of the lungs by tuberculin has recently been dealt with by Dr. H. Batty Shaw in our columns,[1] but Professor McCall Anderson has done good service in calling attention to the value of tuberculin in the diagnosis and treatment of tuberculosis cutis in the annual address which he delivered on May 24th before the Dermatological Society of Great Britain and Ireland. When first introduced by Koch great eagerness was displayed to obtain the preparation, and its indiscriminate and injudicious use undoubtedly did harm in some instances. There were, however, observers who, like Professor Anderson, preserved a firm belief in the remedy, and he laid before his hearers an array of facts pointing to its value in the diagnosis and treatment of tuberculosis in the human subject. He narrated the case of a boy, aged eight years, in whom an obscure chronic peritonitis was not only demonstrated to be of a tuberculous nature but was cured by injections of tuberculin, 22 of which were given between July 9th and Oct. 4th. Other cases were also mentioned in which unsuspected foci of disease in the lungs and elsewhere in persons who were the subjects of tuberculosis of the skin were revealed and relieved by the same means. The efficacy of injections of tuberculin in the treatment of lupus vulgaris and other forms of tuberculosis cutis was particularly brought out by a valuable series of cases, the charts and the photographs of which before and after treatment were shown at the meeting. Without wishing to deny that the x ray and, above all, the Finsen light treatment had yielded admirable results and constitute a valuable addition to our therapeutic measures, Professor Anderson pointed out that there were many cases in which the situation or the extent of the lesion rendered these measures unsuitable. He had used the tuberculin treatment continuously since its discovery and had met with no untoward results. Most cases under his care had been benefited and in many the manifestations had entirely disappeared. The preparation used was Koch's old tuberculin and the initial dose for an adult consisted of from a quarter to a half cubic centimetre of a 1 in 1000 solution. This dose was gradually increased according to the constitutional reaction obtained up to as much as one cubic centimetre of pure tuberculin and was administered every third or fourth day, the treatment extending in many cases over a period of six, seven, or more months. At the discussion which followed some of the members stated that they had used the new tuberculin (which is followed by less constitutional reaction and which is prepared in England by Dr. A. E. Wright by heating and triturating cultures of the bacillus tuberculosis) with similarly favourable results and that the process of recovery had been less tedious in some cases than under the light or the x ray treatment. Now that the initial excitement created by Koch's discovery has passed away the subject requires careful consideration and re-investigation at the hands of the profession and Professor Anderson has done well to bring forward so valuable a contribution to the subject.

---

[1] THE LANCET, April 8th, 1905, p. 923.

THE VENTILATION OF TUBE RAILWAYS

WE have little doubt that several schemes have been suggested for the ventilation of tube railways but the plan brought forward by Mr. R. J. Russell, who has sent us a full description of his invention, has at least the merit of simplicity, and we should imagine of small cost also. It is obviously of advantage to be able to utilise to some extent for the purpose the arrangements that already exist. Mr. Russell proposes to convert every station into a pumping ground on a large scale, each station keeping that section of the line served by it free from vitiated air. In order to expel the foul air he proposes, in a word, to use the lifts and hoistways as pumps. Under the lifts and attached to them he would provide strips of felt, leather, or other suitable material which would slide against the partitions or sides of the hoistway so that the lift in its passage up and down would act as a pump and with the aid of suitable flaps or valves would force out the foul air. For the intake of fresh air he proposes to use the stairway shaft, the structural arrangements being such that the fresh air would be delivered and circulated at the farthest convenient point from where the foul air is withdrawn. It is stated that the work in connexion with the installation of this system could be carried out without any delay or interference with the traffic or business of the day and the cost of the installation would be small in comparison with the benefit resulting from the provision of a constant supply of pure air. We presume that it is taken for granted that so long as the stations are supplied with fresh air the motion of the trains through the tunnels would suffice to draw on this supply for the ventilation of the tunnels and trains. In brief, the principle suggested is that of the air pump, using the lifts for ejecting foul air and the existing stairways as a channel for the supply of fresh air. Of course certain difficulties may arise, as in the case when extremes of temperature prevail, and no passenger would be grateful for a system which succeeded in pumping a London fog into the Tube.

THE EARLY DIAGNOSIS OF GLYCOSURIA

AT the meeting of the Paris Academy of Sciences held on May 8th M. Le Goff gave an account of a method by which he had been enabled to determine the presence of the extremely small quantities of sugar which mark the commencement of diabetes. The test depends upon the decolourisation by glucose of methylene blue in an alkaline medium. One cubic centimetre of the liquid to be tested is placed in a test tube together with one cubic centimetre of distilled water and the same quantity of a 10 per cent. solution of potassium hydrate. A film of xylol is placed on the top and the contents of the tube are then warmed by placing the tube in boiling water. A solution of methylene blue of a strength of 1 in 5000 is then added until the blue colour just persists. The amount read off is then divided by seven, which gives the quantity of sugar in grammes per litre. M. Le Goff also applies this method to the estimation of the other reducing substances in the urine of which sugar is not the only one. There are, in addition to the colouring matters of the urine, acetone, certain phenyl bodies and carbohydrates, together with glycosuric acid and its analogues. On the other hand, uric acid, creatinine, albumin, chlorides, and phosphates have no reducing action on methylene blue. It is thus possible to estimate accurately the total reducing power of the urine by means of methylene blue. Methylene blue is not a new reagent in the analysis of urine, but the particular manner in which it is employed in this case is novel and probably an improvement on previous devices.

CONGENITAL WORD BLINDNESS AND CONGENITAL WORD DEAFNESS.

WE have received a reprint of a paper by Dr. C. J. Thomas, assistant medical officer (Education Department) of the London County Council, published in the *Internationales Archiv für Schulhygiene*, Band 1., Heft 2, 1905, drawing attention to the importance from an educational point of view of some forms of congenital aphasia, more especially those of partial character. Dr. Thomas draws attention to the fact that, in spite of the knowledge acquired by physiologists and psychologists of the nature of the nervous mechanism of speech functions, very little application of that knowledge to the practical problems of education has yet taken place and education is still very largely empirical in its methods. For example, no cognisance is taken of the fact, well recognised though it now is, that memories differ in different individuals, in some being largely visual, in others auditory, and in a third group mainly kinæsthetic. As an illustration of the importance of careful study of the processes of memory, especially in those in whom it is defective, Dr. Thomas records in his paper a series of cases of congenital word blindness, a condition which he states to be not at all uncommon, 50 cases having come under his own personal notice. In cases of this type vision is normal as a rule, other memory processes are good and may even be above the average, but there is a defect in the faculty of storing up memories of the meanings of written or printed word symbols. Even the learning of the letters is a matter of great difficulty, although that is usually successfully accomplished after a long struggle, but the learning of words is in most cases an almost insuperable difficulty and yet the child can recognise the word when his kinæsthetic memories are evoked as in spelling it out with voice and lips. The defect is to be attributed to a deficiency or "congenital poverty" of structural elements in the angular gyrus which is the storehouse for visual word memories. A peculiar fact is that in practically all the cases the power of learning Arabic numerals is normal which suggests that the visual memories of numerals are stored in a different area, as is also probably the case with the symbols of musical notation. Dr. Thomas also records a few cases of congenital word deafness in which although the subject hears words he does not understand them. Such children can, however, be taught lip reading and so enabled to follow conversation and also can be taught to speak, when their articulation is usually quite natural. It is easy to see that such cases, apart from such special investigation and training, are apt to be regarded as imbeciles since though they can hear they do not understand. Dr. Thomas gives the bibliography of his subject which is a very short one, very few cases being as yet recorded; in fact, until now only three cases of congenital word deafness are on record, while only a comparatively small number of cases of congenital word blindness have hitherto been published. The subject is one of great importance, especially to medical officers of schools and educational authorities, since it is essential that in such cases of partial defect appropriate measures shall be taken to educate the children and this is only possible when the defect is properly recognised and classified. Dr. Thomas's paper forms an interesting and highly suggestive contribution to a subject hitherto neglected.

THE DANGERS OF BLAST FURNACE GAS.

AT a recent meeting of the Iron and Steel Institute Mr. D. H. Thwaite communicated an interesting and practical paper on accidents due to the asphyxiation of blast furnace workmen. As is well known, the chief valuable thermal constituent of blast furnace gas is carbon monoxide which, however, is unfortunately very poisonous. Mr. Thwaite has had experience of fatalities which were due to the permeation of gas through the subsoil. In one instance the ground was comparatively moist outside the building but it was still permeable. When the subsoil is dried by proximity to a flue it becomes as permeable as a sieve and on examining the subsoil gas in proximity to a flue in which the gas is slightly under pressure poisonous gas will readily be found. Moreover, crude furnace gas in flowing through the subsoil becomes richer in carbon monoxide and is therefore more dangerous. Also, the gas will find its way into any habitable structure overhead unless the upper ground surface is asphalted or cemented. The subsoil immediately beneath any habitable place will obviously be drier, generally speaking, than that of exposed open-air places and furnace gas escaping from a gas flue will, of course, follow the direction of least resistance. Incidentally Mr. Thwaite describes an apparatus designed for the rapid detection of carbon monoxide in the air. It depends upon the production of a black precipitate in the solution which consists of reduced palladium and not of carbon as stated by Mr. Thwaite. In testing for leakage in an underground furnace gas main he employs acetylene gas which is introduced into the gas main under slight pressure, its peculiar odour being easily identified should any escape occur through the subsoil. Finally he has drawn up the following suggestions with a view of securing a minimum of fatalities from the causes indicated. Where practicable all gas flues and gas pipes should be placed above the ground and, if possible, above breathing level. If the gas flues are underground they should be built of blue bricks set in cement Gas-flue manholes should be equipped with lids which will prevent leakage of the gas. All habitable buildings should be thoroughly ventilated. The ground surface below the building should be covered with a layer of cement and an open-air space should be formed between the cemented surface and the floor boards of the building. Forced ventilation should be the principle adopted for all occupied buildings in iron and steel works. An air-supply tapped from the cold blast main may be found useful in this connexion. The gas engine exhaust pipes should terminate at a considerable altitude above the work floors and part of the air drawn into the air tube of the blowing engine should be supplied from the engine house. Especial precautions should be taken during the cleaning of flues and stoves. Enamel-lettered warning notices should be prominently posted throughout the works. Fines should be imposed on workmen for careless conduct. A paid ambulance corps should be established. During the blow-out period of slag-tapping operations the men should be withdrawn from the zone of escaping gas. The time allowed to be occupied in poking the fuel in the gas producer for individual men should be limited to three minutes. The reversing valve-pits of gas-fired furnaces should be well ventilated. Roll-call checks of labour employed in gas-flue and stove-cleaning operations should be established. If power gas-pipes have to be placed underground, they should be placed in grate-covered open trenches and the pipe flanges should be planed.

THE DETENTION OF LUNATICS IN WORKHOUSES.

IT might reasonably be supposed that the procedure for the detention of a lunatic in a workhouse under the Lunacy Act, 1890, was by this time sufficiently clearly defined. A question as to the construction of the section of the Act dealing with this matter has, however, recently been referred to the Commissioners in Lunacy and they have thought the point raised one calling for an expression of opinion by the law officers of the Crown. A note of the issue dealt with, and of the views held by, the law officers in regard to it may prove of service to such of our readers as are concerned with the administration of the Poor-law. Acting under Section 24, Subsection 4 of the statute mentioned, a justice may, on the strength of two medical certificates in the forms numbered 8 and 10 in the schedule to the Act, make an order for the detention of a lunatic in a workhouse. The order is in Form 11, is addressed to the master of the workhouse, and contains the following passage.

> I —— hereby authorise you to take charge of and, if the workhouse medical officer shall certify it to be necessary, to detain ——.

The workhouse medical officer has already, in Form 10, certified that detention is necessary but this certificate antedates the order. Is a further certificate required and, if so, at what stage is it to be given? The schedule supplies no form for such further certificate and makes no provision for the payment of a fee in respect of it, though this latter omission is, unfortunately, not inconsistent with the spirit of the Act as elsewhere displayed. The opinion of the law officers of the Crown is given in the following words:—

> As a matter of law it is not necessary that the certificate mentioned in Form 11 should be signed at, or immediately after, the making of the order. It must, however, be pointed out that the certificate must be obtained before any detention against the will of the patient takes place. Therefore, whenever the case is such that the power of detention is necessary the certificate should be obtained at once in order that the detention may be justified. Detention may become necessary under circumstances which would not leave time for obtaining the certificates if that should be postponed until the event occurs.

It appears, then, that the detention of a lunatic in a workhouse is an even more complicated business than is generally supposed and that not two but three medical certificates are called for.

CASE OF MYASTHENIA GRAVIS WITH PERSISTENT AND DISEASED THYMUS.

IN the *Journal of Nervous and Mental Disease* for March Dr. Charles W. Burr records a case of myasthenia gravis, with necropsy, which is of interest as adding another to the recorded cases of this disease in which the thymus was either persistent in the adult or persistent and diseased and in which there was lymphoid infiltration of the muscles. The patient was a male, unmarried, aged 30 years, and had always been robust. There was no history of syphilis. After suffering much from headache for some two months he noticed that the right eye began to droop and the muscles of the jaw to grow weak. This weakness then spread to the shoulders and arms. The subsequent symptoms may be summarised as follows: slow speech with weak voice and fatigue in talking, difficulty in swallowing, and increasing general weakness. Within eight weeks from the appearance of the drooping of the eye he could scarcely get out of bed. All movements had become very weak with the exception of those of the tongue. The face was mask-like.

There was no muscular wasting. Sensibility to touch, pain, and *temperature was normal* There was no fever The patient died, mentally clear, about two months after the earliest motor symptoms were noticed In addition to the above, there were visual symptoms not reported, Dr Burr states, in previous cases—namely, contraction of the visual fields, partial reversal of the red and blue fields, and later colour confusion These symptoms, it is suggested, may have been merely coincidental The noteworthy conditions found at the necropsy were as follows the thymus was prominent and weighed 22 grammes, it contained a chronic abscess, the nervous system was normal to the naked eye and microscopically In the muscles were found areas of round cell ("lymphoid") infiltration between the fasciculi Reference is made to previous cases of myasthenia published by others, including Weigert's original case reported in 1901, and to a good bibliography by Hun [1]

THE UNBURIED CHILD AND THE GUARDIANS OF THE POOR OF SOUTHWARK

THE story told by a poor woman, named Campbell, at the Tower Bridge police court on May 27th has been so widely commented upon in the newspapers that the facts disclosed by her need only be recapitulated briefly On May 16th her child died in the Evelina Hospital for Children On the 17th she applied with the death certificate to a relieving officer for an order for burial and was told that her husband was the proper person to make the application On the 18th they went together to the relieving station and were told that they must attend before the committee of the guardians on the 24th On the 24th they attended as directed and the father was informed that before he could be granted the burial order he would have to break stones for the guardians for two days and that then after the order was granted he would have to pay 1*s* weekly until the burial was paid for The father accordingly worked for the guardians on the 25th and the 26th, the money that he earned being retained by them, and on the night of the 26th he received the burial order He afterwards learnt from the undertaker that the funeral could not take place until the 31st, more than a fortnight after the child's death During *the period* which had elapsed *the body had been lying* uncoffined at the hospital If in the whole of the recent history of Bumbledom a more disgraceful story has been told we have failed to observe it Looking at it from the point of view of the hospitals and of those who in sympathy with the efforts of the hospitals by their generosity enable them to relieve the sufferings of the poor in sickness we would ask the Southwark board of guardians to remember that a charitable institution relieved them of the care of the child when sick and that if they could feel no sympathy with the parents they should at least have considered their duty to the community which does not pay rates in order that bodies may be left unburied for a fortnight in summer weather We frequently refer, when dealing with the question *of the support of hospitals by charitable* contributions, to the alternative of causing them to be maintained out of local funds administered by local governing bodies If this would mean making them subservient to such persons as compose the Southwark board of guardians and subjecting the relatives of those bringing the sick to them to conditions similar to those prevailing at Southwark in the case of the burial of the deceased children of the very poor the humbler classes of the community would not be likely to benefit by the change And yet in justice the hospital supported by the rates would either have to be open to all ratepayers or its aid would have to be subject to some such rules and limitations as those which now apply in the case of Poor law relief, with the risk of cases of hardship and of misused discretion such as that described

CORONER'S INQUESTS IN LIVERPOOL

IN an annotation last week under this heading we alluded to the coroner with whose attitude we were compelled to find fault as the Liverpool coroner. This was a slip of the pen The inquest did not take place in Liverpool but in Earlstown, a neighbouring Lancashire town, the coroner being one of the district or divisional county coroners and not the coroner for the city and county borough of Liverpool The relations between the Liverpool city and county borough coroner, Mr T E Sampson, and the medical profession have always been absolutely cordial and we regret to have so worded our article as to make it appear that we were criticising his conduct

THE medical officer of health of the Cape Colony states that for the week ending May 6th the condition of the colony as regards plague was as follows at Port Elizabeth 1 case, that of a European male, was discovered, at East London 1 case, that of a European male, was discovered, at King William's Town 2 cases, the one an Indian male and the other a native male, were discovered, at Fort Beaufort 2 cases, both native males who had just arrived from East London, were discovered Plague infected rodents were found at Port Elizabeth, Uitenhage, King William's Town, and at East London In the last named town one plague-infected cat was also found In other districts of the colony no case of plague in man or other animal was found At Brisbane, for the period April 15th to 20th inclusive, no case of plague occurred The last reported case, that of April 1st, was discharged on April 20th and the plague hospital was closed The last infected rat was found on April 15th As regards Hong Kong, a telegram from the Governor received at the Colonial Office on May 29th states that for the week ending May 27th there were 20 cases of plague and 19 deaths from the disease

THE Colonial Nursing Association will hold its annual meeting on Wednesday next, June 7th, at 3 30 P M, at Sunderland House, Curzon street, London, W, by the invitation of the Duke and Duchess of Marlborough H R H Princess Henry of Battenberg has expressed her intention of being present The Earl of Westmeath will preside and *the speakers* will include the Right Hon Alfred Lyttelton (the Colonial Secretary), Lady Balfour of Burleigh, the Right Hon R B Haldane, K C, M P, Sir Patrick Manson, and Sir John Rodger

THE annual meeting of supporters of the Friedenheim Hospital will be held to-day, June 3rd, at 3 P M, in the Hampstead Conservatoire, Eton avenue N.W, and will be addressed by the Bishop of London and the Duchess of Montrose The chair will be taken by Mr John Langton, chairman of the council

THE forty-fifth annual dinner of King's College, London, will be held at the Hotel Cecil on Monday, June 26th, when Colonel Richard H Jelf, C M G, will take the chair All communications should be addressed to Mr John Chapman, honorary secretary of committee, at the College

A CONFERENCE of imperial, county, and municipal representatives, of medical men and nurses, ministers of religion and district visitors, philanthropists and social workers, will be held at the Town Hall, Pancras road, N W, at 3 30 P M, on Monday next, June 5th

SANITATION AND THE PANAMA CANAL.

THE SOLUTION OF CERTAIN CLIMATIC AND HYGIENIC PROBLEMS.

BY JOHN GEORGE LEIGH.

I.

THE existence of the Pacific Ocean first became known to Europeans through Columbus, who received certain vague accounts of it from natives whom he encountered during the course of his third transatlantic expedition near the mouths of the Orinoco. Heretofore, the great discoverer had believed that by sailing westward he would reach the Indies and the legendary land of Cathay, and this faith and ambition yet stirred him when in May, 1502, he once more, and for the last time, set sail from Spain for the, until recently, unknown New World. He supposed then, and, indeed to the moment of his death, four years later, that the lands which he had discovered were but outposts or a prolongation of the eastern shores of Asia, and it was to reach the Asian mainland through a passage which he imagined lay between the Gulf of Paria, behind Trinidad, and Honduras, that his final voyage was planned. It was not until Balboa, in 1513, crossed the Darien Isthmus and immortalised himself as the first European to set eyes on the "Great South Sea" that navigators recognised that a new continent had been found, and eight more years elapsed before Magellan traversed the wide expanse of the Pacific and determined the geographical relations of Asia and America. From these times to the present there has been scarcely a generation which has not hoped and believed that it would witness, by an engineering feat, a junction of the waters of the Atlantic and Pacific oceans and the creation of a navigable short cut westward to the Orient. During these four centuries, in various parts of the world, many seemingly more difficult enterprises have been attempted with fortunate issue. The same period has seen the development of many more or less promising ventures to achieve an American trans-isthmian canal; but, until to-day, despite great sacrifice of life and lavish expenditure of treasure, no scheme to this end could with assurance be regarded as the precursor of success.

Needless to say, the project has been much discussed from many and conflicting points of view; and even now there appears great diversity of opinion as to the value of the future ocean highway to commerce and its importance as a political and economic factor. With these questions, of course, a medical journal such as THE LANCET has comparatively little concern, and the same remark applies, but with less force, to the impending definite choice of design and manner of construction. There is, however, one aspect of the question—until recently treated with peculiar neglect—which must very closely appeal to all persons interested in sanitary science and the protection of public health, and it is to a consideration of this that the present paper will primarily be devoted. The author is among those who believe that the Panama Canal during the later stages of construction will prove the most striking object lesson ever offered of the benefits to be derived from a well-armed sanitary organisation associated with a great public work, and that it will, when completed, be a potent factor in revolutionising existing trade routes and in bringing about other political and economic changes, not less startling because they are as yet but dimly foreshadowed. The fiats or humours of politicians or engineers may do much to strengthen or to modify these influences but even more powerful will be the effect of the replies to the following questions:—

1. Can the health conditions of the Isthmus be so ameliorated as to prevent, during the period of canal construction, a recurrence of the appalling mortality among the labourers which accompanied the building of the Panama railroad and the work of excavation along the canal route in the days of the de Lesseps Company?

2. What part is the completed canal likely to play in promoting or endangering public health?

To Great Britain these questions should appeal with special force—the first, because it is hoped by the American authorities that much of the labour to be employed in the construction of the canal and its auxiliary works will be drawn from Jamaica and other British West Indian islands; the second, because of the propinquity of the canal to these islands and the possibility that, in default of necessary precautions, the canal may become even more conspicuous as a focus of disease than of commerce. In the latter event the world would lose rather than gain by the success of the enterprise; ports of already doubtful hygienic reputation would be brought nearer and into closer relations, and intercourse between the nations would be seriously interfered with owing to the necessity imposed upon all healthy ports of exercising a strict quarantine against vessels passing the Isthmus.

For convenience, it may be desirable to recall, in as few words as possible, some of the more salient episodes in the history of the Isthmus and of the long-proposed interoceanic canal which bear upon the questions immediately before us. Boundless as was Spanish dominion in the New World, it contained, from the very beginning, the seeds of ultimate and irretrievable decay. The colonists were for the most part mere hunters after the precious metals and disdainful of steady industry; while the mother country, by rigorously excluding from public employment all but its own actual natives, did nothing to prepare the dependencies for eventual freedom. Over the narrow neck of land between Panama Bay and the Caribbean Sea there flowed during many generations an almost continuous stream of wealth destined to enrich Europe or to be the prey of the robbers of the sea. To-day, however, the only reminders of this period visible in the Isthmus are the ruins of Old Panama, six miles north-east of the present city; the remains of some paved roads, over which the treasure-seekers passed and their spoil was carried eastward; a few dilapidated churches; and a slothful and poverty- and often disease-stricken people. After the eighteenth century the old transit routes fell into disuse and Spanish intercourse with the western ports of America was maintained almost entirely by way of Cape Horn and the Cape of Good Hope. Indeed, it was not until 1848 that the Isthmus again became much frequented by foreigners. Following the cession of California to the United States and the gold discoveries beyond the Rocky Mountains, many thousands of people passed through Panama on their way to San Francisco or to Oregon. To take advantage of this movement an American company pushed on with feverish activity the construction of the Panama railroad, which was opened to public use in 1855; and thenceforward, it is not too much to say, the completion and ownership by the United States of an interoceanic canal become an article of political faith and a question merely of years.

It is unnecessary more than to refer to Baron Ferdinand de Lesseps's ill-starred enterprise, to the crash of January, 1889, and the mass of unsavoury facts brought to light during the course of the consequent liquidation. In October, 1894, a new company was organised to keep clear as far as practicable the line of the canal, already in large degree obliterated by the rank and luxuriant tropical vegetation, to preserve from irreparable decay the plant and buildings of its predecessor, and to obtain an authoritative and independent opinion concerning the feasibility—at that time much doubted—of the completion of the canal. Notable success, far greater, indeed, than had been anticipated, attended the performance of these duties. Towards the close of 1898, after investigations extending over two and a half years, an advisory committee of engineers representing France, England, Germany, and the United States, united in a report, which has since been admitted to be conclusive, demonstrating the practicability of a canal with locks and the possibility—attended, however, with greater difficulties—of a channel level with the oceans. Public opinion in the United States had, up to this time, almost unanimously favoured what is known as the Nicaragua route. The Administration, however, wisely refused to ignore the report to which reference has been made, and in 1899 nominated a commission to investigate "all possible routes. [illegible] first instance, reported favourably to [illegible] but immediately reversed its finding [illegible] that the New Panama Canal Company was ready to transfer to the United States for £8,000,000 all its properties and concessions, the whole representing a capital expenditure up to that date of more than £60,000,000. Many difficulties, however, called for settlement before this advantageous offer could be definitely accepted. In Congress the necessary legislation was for a long time obstructed by those who honestly believed the Nicaragua to be the better route and by others who, in the interests of the transcontinental railways, found the evil climatic reputation of Panama a welcome excuse for staying the progress of any potential competitive canal Then followed opposition from the Colombian Senate, actuated by belief that better financial terms might be squeezed out of the wealthy United States—a hope rudely dispelled in November 1903 by the successful revolutionary movement in the Isthmus and the creation of the independent Republic of Panama Between this community and the United States there now exists a compact, to several provisions of which of great interest to the medical profession, I must later make fuller reference

Having completed the purchase of the property of the canal company and handed over to the Republic of Panama the $10,000 000 agreed upon as compensation for the "rights powers and privileges' specified in the treaty the United States Government was enabled early in May, 1904 to enter into full and undisputed possession of what is known as the Canal Zone—viz all land and water extending five miles on each side of the centre line of the future canal and for a distance of three nautical miles from low water mark at the two ocean terminals In anticipation of this event President Roosevelt had nominated a commission of seven members to continue the work of canal construction and exercise governmental powers in the Canal Zone under supervision of the Secretary of War, and it is of interest to note that in his original letter of instructions—and, indeed, in all his references to the canal—the President laid special stress upon the necessity of efficient sanitary administration For instance, on May 9th, 1904, he wrote as follows to Secretary Taft —

I de ire that every
id workmen from the
ie last have been so

Towards the close of last year it became evident that operations in the isthmus were much hampered by friction between members of the Commission and between the latter and several of the departments working under it It was believed, however, until quite recently that the health department had not materially suffered from these differences and that the Commission's record would bear critical examination, so far, at least as improvement of sanitary conditions was concerned Considerable sensation was consequently aroused by the publication in a Chicago medical journal of the report by Dr C A L Reed President of the American Medical Association, to which the New York correspondent of THE LANCET has recently on several occasions referred There was much in this document signed by so distinguished an authority in his profession to excite disquiet and demand investigation Unfortunately however, the report throughout was so disfigured by bias and often personal animus, and the circumstances of its unauthorised publication were so remarkable, even for America, as to deprive it of much weight Mr Taft nevertheless rightly judged it his duty to bring the communication to the attention of the President and to invite such reply from the incriminated commission as the latter might deem desirable To this reply and a subsequent report from Colonel Gorgas M D, the chief sanitary officer in the Canal Zone it will be necessary for me to allude more fully when discussing the work past and future of the American medical authorities in the Isthmus Although the defence offered by the commission may not, perhaps be complete on all points it must be regarded for the time as sufficient reply to Dr Reed's often extreme and somewhat flippant remarks Seldom indeed, has a professional report evoked more severe condemnation than that contained in the following letter from President Roosevelt to the Secretary of War —

h together with the report
e by the Commission It

so to give it, and until the answer
Commission) was, without your kn

port valuable to the
with the duty of

be a commissioner
ie assumed to make
Secretary of War he
ent on so important
a subject and to observe the proprieties as to its publication

Dr Reed has possibly found some consolation for this official rebuff in the reflection that his revelations hastened by a few days the fall of the Canal Commission which he so roundly condemned It had long been expected that the President would request the resignation of most of the members and that this would be followed by a radical change of *personnel* and rearrangement of duties, and these anticipations were more than realised by an order announced on April 3rd, just as the President was starting on his western trip providing for a complete reorganisation of Isthmian affairs This, to all intents and purposes, reduced the number of commissioners armed with executive powers to three—Mr Theodore P Shonts, the chairman Mr John F Wallace the chief engineer, and Mr Charles E Magoon, the governor of the canal zone and head of a newly created department concerned with the administration of laws and sanitation

More closely connected with the health problem than at first sight appears is the question of the design of the canal The Isthmian Canal Commission of 1899 1901 recommended a plan for the completion of a canal with locks based in large measure upon the project formulated by the committee of technical experts appointed by the second French company It also reported that up to that time there had been excavated about 77 000 000 cubic yards of earth and rock, but that of this total only 39,586 332 cubic yards would be of value in connexion with the new plan The latter would call for the further excavation of nearly 100 000,000 cubic yards and the total cost of completing the canal, irrespective of payments to the French company and the Colombian Government, was estimated at in round figures £29,740 000 Up to a few months ago there seemed little doubt that such a canal would be the limit of American ambition Since then, however many of the engineers prominently associated with the enterprise have strongly urged the advantages of a water way free from the restrictions of locks They have expressed confidence that such progress can be made and such economies effected by the employment of modern excavating plant in what is known as the great Emperador Culebra cutting that the channel through this might be lowered to the sea level more rapidly and at less cost than had heretofore been regarded as within the limits of possibility They have also arrived at the conclusion that the all important problem of controlling—in the interests of the safety of the canal and of navigation—the immense floods which periodically rush into the region of the canal from the Upper Chagres river can be effectively solved by the construction of an immense dam in the neighbourhood of Gamboa and other regulating works Should these representations prove convincing to the advisory board of engineers which has recently been constituted there is little doubt that Congress will be invited early in the ensuing session to sanction the additional expenditure—according to the very lowest and most favourable estimate £5 000 000—required in connexion with the sea level scheme

So far as navigation is concerned, a sea level canal offers obvious advantages not the least being the lesser time required for crossing a country the climate of which must always be regarded as menacing to health The longer period however which must be allowed for the completion of such a canal cannot fail to have a malign influence upon the returns of mortality and sickness among the labourers and in the same connexion it should be remembered that the lower the general level of the canal the more necessity will there be for disturbance of marsh land reeking

canal line and the relative amount of excavation made by the two French companies and that which will require to be done by the United States Government should it be decided to lower the canal throughout its entire length of 49 07 miles between the six fathom curves in the two oceans to the mean level of the latter The earth and rock removed prior to 1892 is indicated in Fig 2 by the heavier printing while the white space below, to the line representing the canal bottom (35 feet below the level of the oceans), suggests the enormous amount of

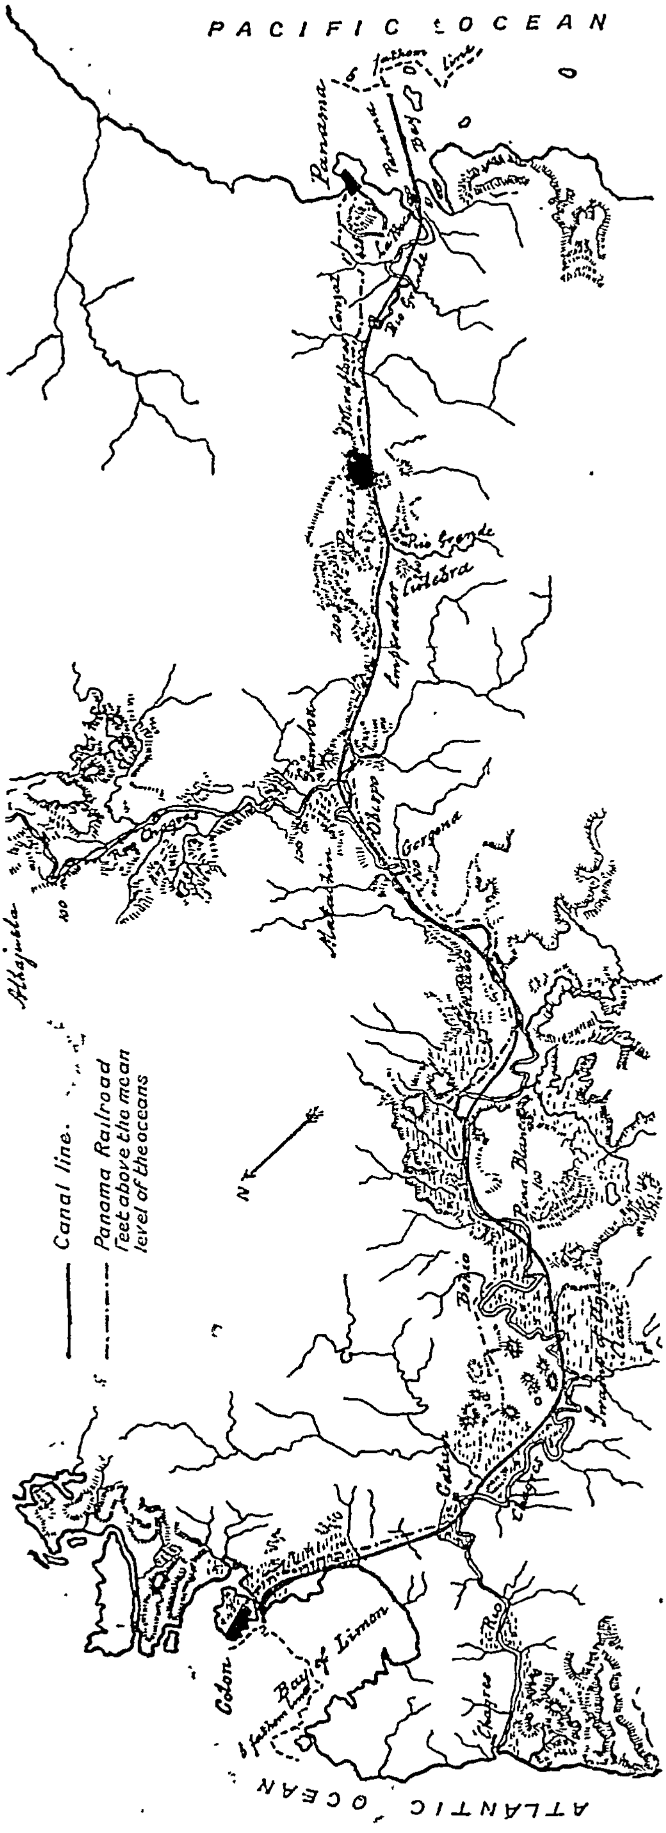

FIG. 1.—General plan of the Panama Canal.

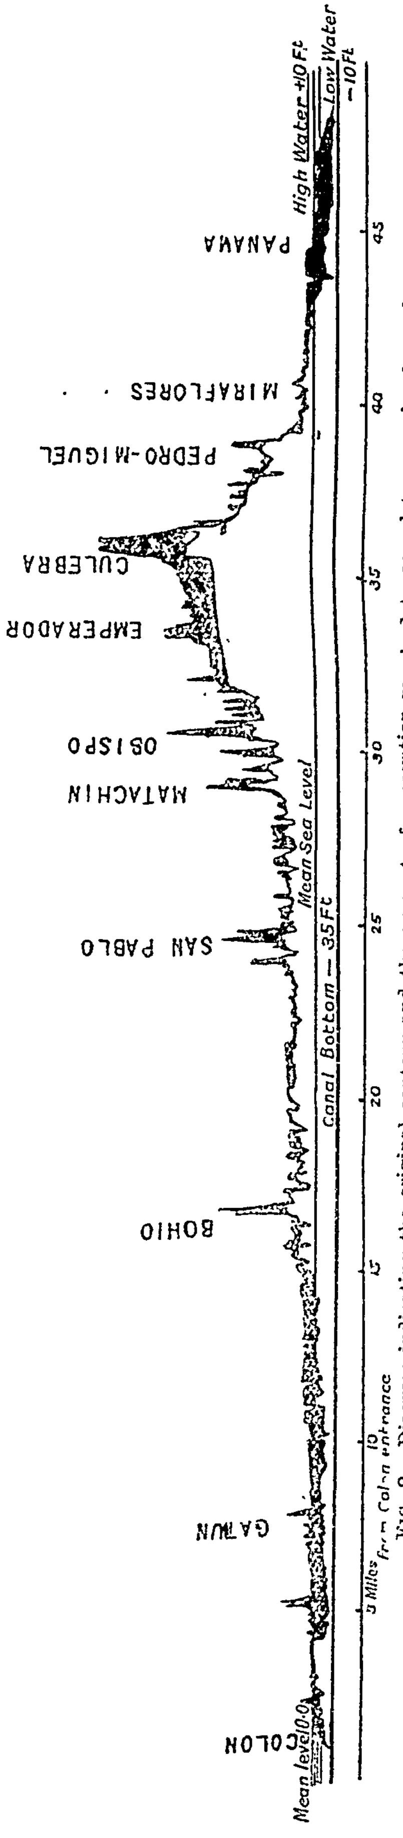

FIG. 2.—Diagram indicating the original contour and the amount of excavation required to complete a sea-level canal.

excavation—most of it in harder material—still required. It should also be noted that the semi-completed sections of the canal as left by the French must first be cleared and then be considerably deepened and widened to realise the standard dimensions demanded by the American engineers—namely, a minimum depth of water of 35 feet, a bottom width of 150 feet, and a top width of 269 feet. The amount of excavation still required in the mountain cutting alone in the case of a tide-level canal will be not less than 186,000,000 cubic yards, or nearly double the amount for the entire heretofore-favoured lock canal. This project contemplated that the limit of excavation in the summit level—i.e., the section between Obispo and the proposed lock at Pedro-Miguel (see Fig. 2)—would be 60 feet above mean sea-level and that by the construction of a dam at Bohio the flood waters of the Chagres would be impounded and create a deep lake extending from the Bohio locks to Obispo—the level of which would be identical with that of the channel through the mountain cutting. Thus, to all intents and purposes there would be effected, as against the sea-level project, a saving of from 12 to 13 miles of excavation, which owing to climatic and topographical conditions threaten danger to health not only during the period of construction but even perhaps after the opening of the canal.

Various estimates have been made as to the time required to complete the Panama Canal. The most sanguine suggest that a channel might, if the high-level and lock design were adopted, be opened to navigation in between eight and nine years from the present time and that a period half as long again would be demanded in the case of a sea-level canal. This difference, admitted by engineers who favour the last-mentioned scheme, calls for the serious consideration of American medical men who, having knowledge of the Isthmian climate, have hitherto refrained from pressing their views upon the Administration and Legislature. I have great faith that, under the direction of such authorities as Dr. Gorgas, Dr. John W. Ross, Dr. H. R. Carter, Dr. Louis A. La Garde, Dr. L. W. Spratling, and others whose names and duties will call for mention later, we may look forward to a very remarkable diminution of sickness and mortality among the workers along the canal route, as compared with the period of earlier excavation; and it is quite possible that the notable advances which have been made in tropical [illegible] gard to the [illegible] be instru- [illegible] e Isthmus. It is obvious, however, that the longer the time devoted to the work of construction the greater must be the risk of abnormal mortality among the labourers and supervisors of their work and this despite compensations resulting from [illegible] to which I shall more definitely [illegible] le. This being so it seems not [illegible], before the fateful decision, the last word should be spoken, not by the aspiring engineer but by the profession which will be held mainly responsible should the prophecies of ill be justified by events.

[illegible] te, which I [illegible], perhaps, be [illegible] the canal re[illegible] ring upon the climate is the absence [illegible] so-called. East and west of [illegible] is a noticeable break in the m[illegible] America as the Cordillera—which, under various names and aspects, stretches from the extremity of South America to almost the mouth of the Mackenzie River and the Arctic Ocean. Adjacent to the canal line its place is occupied by a series of more or less isolated peaks (*cerros*) of no great altitude which, although composed for the most part of volcanic rocks, are obviously not of volcanic origin. From Colon to Gatun the alluvial plain of the Chagres is bordered by the Mindi Hills and Sierra Quebrancha, the extreme height of which is 200 feet above mean sea level, and these, as well as the adjacent Monkey, Lion, and Tiger Hills still show signs of erosion by the sea. It is only after passing San Pablo that the canal enters what may be described as a mountainous region, heralded, as it were, by hills at Mamei, Juan Grande, and Matachin, and culminating in the so called continental divide, which includes the Emperador and Culebra peaks. Even here the elevation is little more than 300 feet above sea level, with hills on either side rising to about 650 feet. From Pedro-Miguel to the valley of the Rio Grande the descent is comparatively sharp, the most noteworthy elevation on the Pacific slope being the Cerro d'Ancon (420 feet) in the immediate neighbourhood of the city of Panama.

(To be continued.)

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XIV.[1]

THE PRESENT STATE OF MEDICAL EDUCATION—(*Continued*).

The General Medical Council and the Final Examinations.

THE fact that the medical education of the country is, speaking a little generally, all arranged upon the same plan enables the General Medical Council, as the supreme educational authority under the Privy Council, to adopt one simple process of inspection for each of the qualifying centres, a system as simple as it is drastic. The General Medical Council deputes a visitor, a member of the Council, and an inspector, not a member of the Council, who attend from time to time as the Council directs at the qualifying examinations of the body in question. The visitor and inspector can attend together or separately as they are instructed, and can make joint or several reports. They read some of the candidates' papers and make their own marks upon them, which they afterwards compare with the marks made by the examiners. They listen to the clinical and oral examinations of the candidates and take note of the style of questions that are asked and the style of answer that is accepted. They observe the facilities provided for convenient examination of the candidates, the supply of instruments and pathological specimens, the precautions against copying, the amount of time allotted to the examination *vivâ voce* of a candidate or the answering of a written question. And finally, they attend at the adjudication of the examiners upon the candidates' merits. In this thorough way they can see if the examination is kept at a proper standard and if the student obtains fair play, and there is no doubt that the criticisms of the Council's delegates, though sometimes resented by the criticised educational body, have bee[illegible] a high general standard of [illegible] the last observations made by [illegible] sitors of the General Medical Council in regard to the final examinations of all the qualifying bodies which now follows merits careful attention, for we can see that the supervision of the Council is very real and minute. The strictures which have been passed in some directions show that all qualifying bodies, whatever their position, are treated with the same respect, while the value of the work is proved by the fact that an indifferent report on one occasion is observed to be followed by a good report on the next occasion.

UNIVERSITY OF OXFORD.—The final medical examination of the University of Oxford was reported upon to the Council in 1902, to the surprise of everyone, as not being a sufficiently rigid test of medical knowledge. A further visitation and inspection was arranged for and took place at the end of 1904, with the result that the previous condemnatory verdict was practically reversed. The arrangements were found to be generally good; the standard of pathology was high and the candidates were not too liberally marked; the written and clinical examinations in medicine were satisfactory; the material brought together for the *vivâ-voce* examination in clinical surgery was especially noted as excellen[illegible] ination in practical surgery was found t[illegible] omments upon the tests in [illegible] quite so cordial, the replies of the candidates showing hardly so high a standard of knowledge as had been displayed in medicine and surgery, but the examinations were found by the inspector and visitor to be "as a whole as satisfactory as any examinations we have visited," so that the stigma has been definitely removed from the most ancient of our Universities of providing an inadequate trial of knowledge before granting one of its highest degrees.

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., and XIII. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), and May 6th (p. 1218), 13th (p. 1287), 20th (p. 1375), and 27th (p. 1449), 1905, respectively.

UNIVERSITY OF CAMBRIDGE.—The report of the inspector and visitor was quite satisfactory. The examination in pathology, in both parts, was commended particularly. In Part I. the examination in pharmacology was a practical and useful one. A separate paper in therapeutics and prescription writing was held to be an important innovation in the clinical examination in medicine. This consisted of a written report on a case in the wards, with subsequent oral examination thereon, supplemented by an examination of each candidate by two examiners on out-patients, and the inspector and visitor reported that "it was a very complete and satisfactory test." In surgery the examination was considered well arranged but the absence of a separate examination in ophthalmology came in for notice. Also, it was found that the marks obtainable for the written and oral examinations in medicine and surgery at the final examination exceeded those for the clinical and practical portion of the examination, a circumstance which the General Medical Council and all practical educationists think should not occur. But no serious fault was found with the final examinations for medical and surgical degrees at Cambridge.

UNIVERSITY OF LONDON.—The final medical examinations of the University of London were reported upon to the Council in 1903 in not wholly favourable terms, the chief insufficiencies noted being the unpractical character of the tests as shown by the system of marking and the low level of the examination in surgery. A further inspection and visitation was arranged for at an early date and the resulting report was presented to the Council on Saturday last. As in the case of Oxford, the previous adverse verdict was changed. All the plans for the written papers were found to be satisfactory and although there was a hitch in the arrangements for the examination in clinical medicine at one of the hospitals the circumstances were peculiar and allowance was made for them. The tests in written and clinical medicine were found to be, as on the previous occasion, quite satisfactory and well responded to by the condidates, who also acquitted themselves well at a thorough *vivâ-voce* examination. The questions set in systematic surgery were considered practical and those answers read by the inspector were creditable to the student; while it was specially stated that the standard of the examination in clinical surgery was high. In the third examination, the full marks being 150 and the pass mark 75, ten candidates out of 18 obtained more than 100 and four received about 75, so that the quality of the examined was clearly good. The practical examinations in pathology and forensic medicine were described as searching and those in midwifery and gynæcology as very full and practical, from which it may be gathered that the General Medical Council is perfectly certain now that the medical degree, universally believed to be the hardest of attainment in the kingdom, is a guarantee that its possessor is a thoroughly good all-round man.

UNIVERSITY OF DURHAM.—The inspector and visitor reported the final examination as satisfactory, pointing out that provision had been made for practical examinations in diseases of the skin and of the eye. The absence of similar provision in the matter of otology was noticed. The marks awarded for the written, oral, and clinical portions of the examinations were found to be each valued at 100 per cent., but a candidate who failed to obtain 50 per cent. either in clinical medicine or in clinical surgery was rejected, a provision which meets the defect. The general conclusion arrived at was that "the final examinations for degrees in medicine and surgery of the University of Durham are of a high standard."

VICTORIA UNIVERSITY.—The examinations were passed as "of a most satisfactory character—comprehensive in their scope and systematically and efficiently conducted." But there was again no examination in ophthalmic surgery while too much stress was laid upon chemical toxicology.

UNIVERSITY OF BIRMINGHAM.—The examination for the degrees of M.B. and B.Ch. was, in the opinion of the inspector and visitor, a practical examination of a high standard, well planned and well carried out. The absence of examination in hygiene was commented upon but the practical testing of the candidates in pathology and in forensic medicine was commended. The marks both in medicine and in surgery for the written and the oral examinations exceeded those given for the clinical parts of the examination, this being the only stricture passed by the inspector and visitor.

The final examinations at the universities of Scotland had not undergone visitation and inspection at the hands of the General Medical Council for some time until the autumn of 1904, and the resulting reports were not as favourable as might have been expected. The University of Edinburgh in particular came in for a considerable amount of criticism, while by an error of arrangement in printing certain comments which were intended apparently to apply to the University of Edinburgh only were made to apply to the other Scottish universities.

UNIVERSITY OF EDINBURGH.—With regard to the oral examinations the inspector and visitor made no objections, finding that in medicine "well adapted to elicit the knowledge and attainments of the candidates" and that in midwifery "excellent." But the clinical examinations, which were especially commended by the delegates of the General Medical Council some ten years ago as being a higher order of test than was laid down by other examining bodies, did not escape comment, the clinical examination in surgery being condemned as not practical and the method of its conduct being censured. This report gave rise to an acrimonious debate at the General Medical Council, the inspector and visitor being accused of having exceeded their duties. The justice of a substantial portion of their strictures was, however, directly or indirectly admitted and the spirit of antagonism that was roused by a manifestly honest report did not find much favour outside the Council chamber.

UNIVERSITY OF GLASGOW.—The visitor and inspector expressed themselves as much pleased with the final examinations of this university, reporting the examinations in medicine and midwifery as most satisfactory and those in clinical, oral, and practical surgery as having "reached a standard that can hardly be beaten."

UNIVERSITY OF ABERDEEN.—The reporter for the Council found the examination "a good one and in some points an excellent one," the criticism only amounting to remarks upon detail, concerning which the reporter said that the standard for the whole examination could easily be brought up to the same level as that which characterised the greater part.

UNIVERSITY OF ST. ANDREWS.—The visitor and inspector reported the final examinations as "sufficient." The written and oral examinations were all found satisfactory but the clinical examinations in medicine and surgery were too limited. In the inspection of these examinations the possibility of a student having had access in the hospital to patients upon whose clinical condition he might afterwards have to report was mooted, but those responsible for the conduct of the examination warmly resented the suggestion.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).—The inspector and visitor reported that there was an excellent oral examination in medicine, as well as a practical and oral one in pathology, the absence of *vivâ voce* testing having been previously noticed. But all the oral examinations in the University of Dublin were conducted by a single examiner. A separate examination in ophthalmic surgery was recommended and the inspector and visitor were of the general opinion that the final examinations of the University of Dublin were good tests.

ROYAL UNIVERSITY OF IRELAND.—Here the inspector and visitor found that too many candidates were examined simultaneously to admit of efficient personal surveillance. At each part of the surgical examination candidates were examined separately by one examiner only. The percentage of marks for clinical surgery seemed insufficient but the examiners in pathology, midwifery, and gynæcology gave an excellent practical examination. The conclusion of the inspector and visitor was that the final examination of the Royal University of Ireland was adequate but they thought that the details of the examination might with advantage be systematised.

CONJOINT BOARD OF ENGLAND.—The arrangements for the different parts of the examination were found excellent. There was no hitch or delay in any part and, considering the large number of candidates, the organisation was looked upon as perfect. The system of marking came in for criticism, inasmuch as it is still possible for a candidate who has done badly in his clinical examination to recoup himself *viva voce* The oral and practical examinations in medicine were considered satisfactory, but attention was called to the *absence of special examinations in ophthalmic and aural* surgery There was no examination in operative surgery on the cadaver, for it was not possible to obtain a sufficient supply of subjects The examination as a whole was well reported upon.

CONJOINT BOARD OF SCOTLAND —The percentage of candidates who passed the examination at Edinburgh and Glasgow was almost identical, being 44 8 and 45 0 per cent respectively There were defects in spelling and in composition in the papers of some of the candidates and, as showing the important bearing of general upon medical education, it was added that the majority of the ill-educated candidates did not pass the examination Differences existed between the clinical examinations in medicine and in surgery as conducted at Edinburgh and at Glasgow but in both places there was no examination in operative surgery on the dead subject and no clinical examination in ophthalmic surgery No questions relating to ophthalmic or aural affections were put at the written examination at either place, nor were questions asked upon the ordinary injuries and diseases of the eye and ear At Edinburgh one case only was given at the surgical clinical examination An arrangement by which pathology and materia medica and pharmacy were made the subjects of a separate examination was commended but it was pointed out that morbid anatomy should also be recognised at the examination in medicine and surgery At this examination it was noted that the examiners were in a hurry and that some of the papers were overmarked, with the result that a bad clinical examination might be counterbalanced The plan of sending round a schedule was also criticised, as it might induce charitable examiners to stretch a point in favour of candidates who could be seen by the schedule to have nearly reached the pass mark *Despite these objections the inspector and* visitor came to the conclusion that the examination answered its purpose as a sufficient final test, though they added, "We think that the arrangements and system of marking at the written examination might be with advantage revised "

CONJOINT BOARD OF IRELAND —The main criticism of the inspector and visitor of the final examination of this Board was that the Irish Royal Colleges allowed candidates at their final examination to pass "piecemeal " If a candidate was referred only on those subjects in which he failed they would put forward the recommendation of the General Medical Council that "a percentage of not less than 60 per cent —supposing that the pass requirement be 50 per cent —should exempt from re examination in such subject " The same pass standard—60 per cent —might also advantageously be laid down for candidates who presented themselves for examination in a single subject only The inspector and visitor commented upon the utility or inutility of including mental disease as a special subject in the final of an exa*mination for general practitioners and alluded to the absence* of systematic examination in urine testing and the dearth of questions in anatomy in an otherwise well conducted examination in operative surgery The visitor and inspector appear to have thought that the oral examinations in midwifery, forensic medicine, and hygiene were not of a sufficiently demonstrative or practical character and expressed also their views as regards the examination of foreign candidates They saw no objection to their being allowed if necessary, the use of a dictionary at the written examination but considered that to permit a foreigner to write his answers to the papers in his own language and to have them translated into English by an interpreter and to admit an interpreter to the clinical examinations might give rise to an objectionable precedent. Viewing the examination as a whole they were of opinion that it was a fair and carefully conducted one, fulfilling its purpose as a test of medical knowledge

SOCIETY OF APOTHECARIES OF LONDON —The report of the visitor and inspector was brief and satisfactory They testified to the great care and thoroughness with which the whole examination was conducted but pointed out that there was no special examination in ophthalmic surgery and that the art of prescribing should have more attention at an examination instituted by the Society of Apothecaries

APOTHECARIES HALL OF IRELAND —The arrangements for the examination were considered satisfactory The preliminary education of the candidates, only two, appeared very defective A further inspection again found the examination satisfactory but the candidates of very poor quality

It will be realised from these reports that in its duty of maintaining the medical education of the country at a high standard the General Medical Council spares no pains and favours no persons The Universities of Oxford, London, and Edinburgh have been called to order as freely as any corporation The precautions [illegible] examinations are all directed [illegible] towards eliminating the elemer [illegible] from the results—concerning this point more will have to be said—and towards the practical equipment of the medical man for his public duties Notice, for example, the stress that is laid on the absence of attention to ophthalmology, which is a pertinent comment on the widespread usurpation by opticians of medical duties

(*To be continued*)

THE OPTICAL CONVENTION

IN accordance with an announcement in our issue last week the Optical Convention was commenced on May 30th at the Northampton Institute, Clerkenwell, E C, when the President, Dr R T Glazebrook, F R S, Director of the National Physical Laboratory, opened the proceedings with an interesting address on the objects of the meeting and on the growth of optical science The growth of the science at the end of the seventeenth century, he said, was due to two men—Christian Huyghens and Isaac Newton Each appears to have been directed to theoretical optics from a desire to improve the telescope for astronomical purposes Each was in his own way a mechanic—Huyghens built telescopes and clocks, Newton at the beginning of his optical work applied himself to the grinding of optical glasses to figures other than spherical Huyghens and Newton were the authors of the two rival theories of optics which held the field for more than 100 years to the days of *Young and Fresnel* That period was *not very fruitful* either in theory or practice, but Fresnel by his work established Huyghens s theory, and though he did not directly add much to practical optics he entirely changed the position from which the theory of optical instruments has to be regarded Recent progress in the theory of the telescope, the microscope, and the spectroscope is based on his work The work of the two Herschels and Airy at the early part of the last century was alluded to and the important part in the development of English optics taken by Messrs Chance through their introduction of optical glass was mentioned It was pointed out however, that by the middle of the century there was a marked separation between the theoretical and practical workers so that when photography was invented by Daguerre, Airy s work on the aberrations of a lens and Hamilton s important theorems on rays were unknown to the lens designers Thus for many years the photographic lens developed empirically Some account of the change in the position due to the work of Ernst Abbe and the development of this work at Jena and [illegible] ead during the meet [illegible] ruments which was [illegible] rce of considerable attraction A number of practical demonstrations was given in the laboratories The members of the organising committee may be congratulated on the excellent and instructive catalogue which they published It contains a preface by Dr Glazebrook in which the object of the convention is defin [illegible] nd cooperation men [illegible] om all sides of the q [illegible]

In the catalogue [illegible] were arranged in classes, each class being preceded by a short introduction giving a general description of the instruments included in the class Special attention was paid to convenience of reference and in addition to a complete table of contents an alphabetical list of exhibitors and an index of instruments were provided In addition to the more strictly optical instruments many other types of scientific apparatus were included, thus one class was devoted to meteorological instruments and thermometers, another to laboratory instruments; mathematical, drawing, and calculating appliances were also shown. In one section, under "Tools and Materials," was to be found a selection of optical glass by the great glass-making and lighthouse firm—Messrs. Chance Brothers, of Birmingham. Messrs. Powell and Sons, of the Whitefriars Glass Works, had an interesting exhibit of thermometer glass and Messrs. George Colver and other firms showed tools and illustrated processes of manufacture. Another section, "Simple Optical Elements," included an exhibit of accurate work in prisms and plates by Messrs. Hilger and diffraction gratings by Lord Blythswood. The two most important classes in which the excellence of the English work was most apparent was perhaps those of surveying instruments and microscopes; these were both well represented and the exhibits were of special interest. "Spectacles and Eyeglasses" was also an important section, including all the best known makers. A fine historical collection was sent by Mr. M. W. Dunscombe of Bristol, and a "projection apparatus" was the exhibit, shown in action, of a complete lighthouse apparatus of the fourth order by Messrs. Chance Brothers.

Of other classes of exhibits may be mentioned "Telescopes and Binoculars," "Photographic Apparatus," "Photometric Apparatus," and "Ophthalmic Instruments and Appliances." In the class devoted to optical measuring instruments some admirable work was exhibited by the Cambridge Scientific Instrument Company and by Messrs. Hilger. Instruments of special interest and novelty were shown by Professor Poynting, Professor Watkin, Mr. Marrow, and Mr. J. R. Milne of Edinburgh.

THE EPIDEMIC OF FAINTING AMONG SCHOOL-GIRLS AT CLOWNE, DERBYSHIRE.

DURING the past three weeks a curious epidemic of fainting has occurred among the girls in the council (elementary) schools at Clowne, a small coal-mining town in Derbyshire. Since last summer holidays the teachers have frequently observed something objectionable about the atmosphere of the class-room in which most of the cases occurred and from time to time solitary cases of fainting were noted. But suddenly a number of cases of fainting occurred, there being no less than 46 cases between May 17th and 22nd. The infants in an adjoining room were not affected. After the first 16 cases an escape of gas was noticed in the lobby. The leakage was stopped but on the next day eight other girls fainted. The school was closed from the Friday till the following Monday, but on resuming school fresh cases occurred. The school was again closed and the county council authorities were notified, with the result that Dr. S. Barwise, the county medical officer, went to Clowne and made an extensive investigation. The fainting fits lasted for a quarter to half an hour and were accompanied by shivers, spasms, and rigidity. The patients were left in a weak condition and many required to be assisted or to be carried home. We are indebted to Dr. Ferris of Clowne, a manager of the schools, for a copy of Dr. Barwise's first report.

County Offices, St. Mary's Gate, Derby, May 24th, 1905.

DEAR SIR,—I went over yesterday to the Clowne schools and examined the class-rooms which were involved in the attacks of fainting in the school. From the symptoms described to me by the teacher, Miss Chambers, and by the medical man who was called in to attend to the children, there can be no doubt that the attacks are either due to poisoning by carbon monoxide or have a nervous origin. If due to carbon monoxide the only cause which I could discover for the presence of this gas would be an escape of coal gas. There have been several minor escapes of coal gas through the school pipes but they were not, in my opinion, sufficient to cause the trouble. It is, however, possible that there is a leaky main in the street and that coal gas finds its way into the school through the foundations. I pointed this out to Mr. Elson, the surface manager of the Shire Oaks Colliery Company, who are the owners of the gas-supply, and he promised me that he would have the main examined. Mr. Elson also informed me that no water gas was mixed with the gas. I examined the heating apparatus and am of opinion that this is not to blame, although it requires some attention. I made the tests recommended by the Home Office for the presence of carbon monoxide but failed to find it. I have, however, left some mice exposed to the air and I will have their blood examined.

I found that the open fireplaces throughout the school have been stopped up. These should all be opened forthwith. I recommend that the class-rooms involved should be opened again as soon as the chimneys have been swept and the fires have been lighted. I would also suggest that the particular class room involved should be used for boys who are not so amenable to suggestive influence as girls. Pending the result of the examination of the mice which have been exposed to the atmosphere in the schools I recommend: (1) that the open fires should for the present be kept constantly burning while the children are in school; (2) that windows should be kept open; (3) that gas should be turned off at the meter; and (4) the hot-water apparatus should not be used.

It will not be necessary to use it while there are open fires. I find that the floor space has not been concreted and that the hot-water pipes are below the floor boards on one side of the room. The space under the school should certainly be concreted all over and the water pipes brought above the level of the floor. This is a matter, however, which need not be gone into until the summer holidays.

Yours faithfully,
SIDNEY BARWISE.

E. A. Hall, Esq., Solicitor,
Clerk to the Clowne Council Schools, Eckington.

Mr. G. L. Godwin has been ill during the course of the epidemic, but he was kind enough to give our representative such information as was known. It appears that the mice were quite unaffected by the atmosphere of the class-room and Dr. Barwise has found no carbon monoxide in their blood. A test for excess of carbon dioxide in the atmosphere of the room gave a negative result. The floor was taken up and the gas-pipes were carefully examined but no leakage was discovered. The interesting experiment was tried of putting a class of boys into the room in question, but after three days no case of fainting occurred. Mr. Godwin is personally acquainted with each child that has been affected and is of opinion that most of the girls affected were among the poorest of the scholars who perhaps were not sufficiently fed. He considers that many of the girls were genuinely affected but that later other girls followed suit, either in imitation or from sympathy. It should be stated that the Clowne sanitary inspector, Mr. Bradley, has carefully examined the drains and so far has not detected anything wrong with the sewage arrangements. Some of the old people of the town have advanced a theory, based on their previous mining experience, that the epidemic may be due to "after-damp." It is a fact that a "fault" runs through the ground under the school and as the recent earthquake was distinctly felt in Clowne there is a possibility that there may be a leakage of "after-damp" due to this geological disturbance.

THE GERMAN SURGICAL CONGRESS.[1]

(Concluded from p. 1456.)

The Significance of Cryoscopy in Disease of the Kidneys.

Professor ROVSING (Copenhagen) expressed the opinion that the usefulness of cryoscopy had been overrated as a means of ascertaining the functional competence of the kidneys. The kidneys might be healthy even when the freezing point of the blood was from $-0\cdot60$ to $-0\cdot67^\circ$C., and might act imperfectly when the freezing point was normal. The surest diagnostic method was, in his opinion, the estimation of the quantity of urea. When the quantity of urea was normal the kidney was healthy but it was not to be concluded from a reduction of the urea that the other kidney was disabled. The case was the same with the phloridzin test; all these tests were valuable when the indications were positive but were worthless when the indications were negative. Death from uræmia was according to his experience rather rare. Of 52 patients on whom nephrectomy was performed up to the year 1901 he had lost seven and of 60 operated on after 1901 he had lost only two, of whom one died from sepsis and the other from hæmorrhage. Tuberculosis of the generative organs and of the bladder was not a contra-indication against nephrectomy. In tuberculosis of the bladder he recommended irrigation by a solution of carbolic acid of 5 per cent. strength, which gave very good results. Ureteral catheterism should always be carried out for the purpose of confirming the diagnosis.

Professor ISRAEL (Berlin) agreed generally with Dr. Rovsing, saying that cryoscopy was not trustworthy because of the many exceptions to the inferences drawn from it. A considerable proportion of his patients would have died if he had abstained from any operation, deterred by the result of cryoscopic observations. The same was the case with the phloridzin test. The authors of these methods failed to distinguish between the essential competence of the kidney and a temporary impairment of its functions. He said that previously to the year 1901 the mortality among the cases under his care was 25 per cent., but since 1901 it had been 10 per cent., the cause of the difference being that the indications for operation were recently modified. Tuberculous cases in an early stage were now operated on as soon as possible but surgical interference was avoided in advanced cases.

---

[1] For this report we wish to tender our sincere thanks to the editor of the *Deutsche Medicinische Wochenschrift*, through whose courtesy it has been forwarded to us by our Berlin correspondent.

Dr. CASPER (Berlin) opposed Professor Israel's views. He said that in order to obtain as uniform results as possible he was in the habit of making his cryoscopic examination two hours after a test breakfast.

Professor KÜMMELL (Hamburg) recommended that cryoscopy should be combined with ureteral catheterism.

Dr. KAPSAMER (Vienna) said that he preferred the phloridzin test to cryoscopy and the indigo-carmine reaction. The time required for sugar to make its appearance in the urine was of importance.

Dr. GOZEL (Prague) reported that he was able to ascertain the presence of tuberculosis of the kidney by conveying the disease to guinea-pigs by inoculation of the suspected urine.

Prostatic Enlargement.

Professor CZERNY (Heidelberg) said that he did not consider early operation to be advisable in prostatic hypertrophy. The question whether the transvesical or the perineal method was the more trustworthy was rather doubtful. The perineal method, which often produced impotence, should be employed only in very advanced life.

Professor KÜMMELL said that he had tried all the operations recommended for the treatment of prostatic enlargement. He had performed Bottini's operation in 51 cases with two deaths immediately and nine deaths afterwards as a sequel to the operation; five patients were left unimproved, three were improved, and the remainder recovered. In 26 cases he had performed castration, the result being that two patients died, two were unimproved, two were improved, and the remainder recovered permanently. He now used the median or high incision by which the prostate was easily made accessible. When the perineal method was chosen the urethra must be opened, the bladder closed by sutures, and a catheter tied in.

Professor ISRAEL was opposed to suturing the bladder and recommended drainage through the perineum.

Dr. FREUDENBERG (Berlin) advocated Bottini's method as the surest and the least dangerous for the patient.

Dr. FRANK (Berlin) said that after Bottini's operation the edges of the prostatic flaps often united so that the result became doubtful.

Growths of the Bladder.

Professor REHN (Frankfort) reported a series of cases of cancer of the bladder occurring among operatives employed in aniline factories and especially one case in which metatases were present in the right ureter and the right kidney.

Dr. SCHWERIN, chief surgeon to the Hoechster Farbwerke, said that he had operated on four cases of cancer of the bladder in workmen of that factory but only one did not relapse. The post-mortem examinations did not show any alteration of the kidneys.

Dr. WEINRICH (Berlin) spoke in favour of the endo-vesical operation for growths of the bladder, malignant growths, of course, excepted. This method was especially suitable for papilloma. If the hæmorrhage was too profuse the operation must be interrupted and resumed at a later period.

Dr. STRAUSS (Frankfort) said that this method was not trustworthy because a papilloma might possibly have a cancerous basis.

Dr. KAPSAMER recommended the galvano-caustic operation for ulcerations of the bladder; in cancers of small size an endo-vesical operation might be performed.

Lipoma of the Fatty Capsule of the Kidney.

Dr. NEUMANN (Berlin) showed a retro-peritoneal lipoma of the fatty capsule of the kidney weighing 3·5 kilogrammes which he had removed from a boy three and a half years of age. After the removal of the growth, which weighed one-third as much as the patient's whole body, the descending colon was deprived of all its blood-vessels and accordingly was resected; the patient has recovered.

Injuries of the Lungs.

Professor GARRÉ (Königsberg) recommended the suture of pulmonary wounds for the purpose of obtaining quicker healing and avoiding infection. The lung must be made accessible by drawing it out through the wound and the divided edges were then brought together with deep sutures. Wounds in the neighbourhood of the hilus must be plugged. A loose plugging of the wounds was afterwards advisable, with deep drainage if required.

Professor KÖNIG (Jena) said that wounds of the lungs had a marked tendency to heal even without operative treatment.

Operations on the Skull.

Dr. STIEDA (Halle) gave a report of the examination of 31 patients operated on for fracture of the skull. In the clinic at Halle the opening in the skull was always closed as soon as possible, the result being an excellent one. The patients in whom primary implantation had been performed were all in good health, and so also were those who had been treated by Muller and König's osteoplastic operation. Epilepsy had developed in only one case. In secondary implantation the results were less satisfactory.

Professor KÜMMELL said that he had obtained good results by trephining in a case of purulent meningitis occurring after a fall from an electric street car. This was of importance, especially for the present epidemic of cerebro-spinal meningitis, as some cases might perhaps be saved by surgical intervention.

Professor FRIEDRICH (Greifswald) said that he had cured epilepsy by trephining. He was of opinion that the brain of epileptics was favourably influenced by Kocher's operation. He showed a patient who had suffered from dementia but had recovered after removal of a cerebral tumour.

Professor W. KORTE (Berlin) was elected President of the next Congress.

MEDICINE AND THE LAW.

A Question under the Diseases of Animals Act, 1894.

AT Stratford on May 27th a man named Lungley was fined £10 and costs for failing to give notice of a case of farcy glanders in the stables of a firm of builders' merchants, his employers. He had called in Mr. J. P. Lee, M.R.C.V.S., to inspect a horse suffering from a sore on the leg. Mr. Lee after examining the horse ordered that it should not be moved and two days later in the presence of Lungley and of another man, also summoned before the magistrates, applied the test for farcy glanders and found the case to be one of glanders. On the next day he called to confirm this decision and was informed that the horse had been slaughtered and the carcass removed. He at once communicated with the London County Council and with an inspector called upon the horse slaughterers implicated and at their premises identified the hide after some delay in obtaining inspection of it. Examination of the head and portions of the carcass by another veterinary surgeon established the case as one of farcy glanders. At the police court the fine inflicted upon the defendant named above was, as has been stated, for failing to notify the disease. The other man employed by the owners of the horse and two men named Orrocks, horse slaughterers, were charged with offences under the Act involved in the removal of the carcass and on their behalf defences were raised based upon the question of whether there was evidence that they knew what the horse had been suffering from and upon other matters which cannot be discussed while they are still under the consideration of the bench. The questions involved are of great importance from the point of view of the public health and it is to be hoped that they will be determined without delay so that if the law is defective it may be strengthened. Otherwise, apparently, a diseased animal can be removed, slaughtered, and its flesh distributed without interference from anyone in the interval which must necessarily elapse in any obscure case between the first onset of the disease when the veterinary surgeon may reasonably ask to be allowed to watch its development and the point at which the matter is formally placed on record as beyond doubt.

Christian Science and the Death of a Child.

An inquest was held recently at Twickenham upon the body of a child eight months old who had been allowed to die by her parents through the influence of Christian [illegible] encouragement afforded by a lady [illegible] her own evidence, had been [illegible] eight years and was in the habit of receiving a guinea a week for her ministrations. A curious feature of the case and one which renders the conduct of the parents more inexcusable lay in the fact that they at first summoned a medical practitioner, Dr. W. F. MacDonogh, who told them that their child was suffering from bronchial pneumonia, gave them directions as to treatment, prescribed, and when the father did not call at his surgery for the medicine offered to send it to the house. The mother apparently was chiefly instrumental in preventing this from being done. A lady, named King, who said that she was licensed to practise medicine in three States in America, was also summoned by the parents later when the child had become hopelessly ill, and she gave evidence to that effect. The father at the inquest professed his belief in Christian Science, and Miss Wilkins stated that she thought that death supervened because she had not sufficient faith in God and because she did not have the case entirely in her hands. This last reason presumably referred to the intervention of Dr. MacDonogh, some part of whose directions seem to have been followed. The jury returned a verdict in accordance with the medical evidence and requested the coroner to censure the father. In such cases when the possible verdict of manslaughter is not returned it is because the evidence is not conclusive as to death being due to the neglect of medical aid and as the parents may still be charged with a minor offence under the Prevention of Cruelty to Children Acts further comment would be out of place.

The Medical Man, the Coroner, and the Pathologist.

An inquest at Wandsworth, adjourned to May 29th from May 2nd by Mr. Troutbeck, has served to show in a somewhat marked manner the very undesirable results which may ensue from the policy adopted by this coroner, apparently without the concurrence of his colleagues, with regard to the making of post-mortem examinations within its jurisdiction. In the case in question a child, aged 17 months, had been taken by her mother, the wife of a labourer, to a medical man who had handed her a bottle of medicine. On the following day the child became very ill and the mother called in another medical practitioner, who came twice during the afternoon, and at 6.45 the child died. Neither of the two medical men who had seen the child during her illness was ordered to make the post-mortem examination, which, as usual, was intrusted to Dr. L. Freyberger. At the inquest the evidence of the second medical man showed that his opinion of the case from his observation immediately before the child died was that it was due to morphine poisoning and this was corroborated to the extent that the first medical man said that the medicine which he had prescribed contained morphine, although the dose he had ordered would have involved the taking of an infinitesimal quantity; but Dr. Freyberger knew nothing of the previous history of the case; he had not attended during life and the gentlemen who had done so, and one of whom according to law should have made the post-mortem examination, were under no obligation either to be present at the necropsy or to inform him upon the subject. Dr. Freyberger's evidence was to the effect that he had not detected any signs of morphine; whether he had made any special effort to do so does not appear from the report before us. Clearly, however, a medical practitioner making a post-mortem examination entirely in the dark as to the history of the deceased's last illness is at a considerable disadvantage. He is likely to be free from such influence as a preconceived opinion may exert; but is this of importance? No medical man in such a case, if his original diagnosis was not borne out by his examination of the body after death, would hesitate, or would have any reason to hesitate, in saying so. On the other hand, in some cases post-mortem observation alone may give the pathologist no clue which will lead him to form a correct opinion. In circumstances not difficult to imagine the natural refusal of the medical men of his district to support Mr. Troutbeck in his unusual, if not unique, position, may lead to a serious failure of justice. Meanwhile unpleasant and undesirable scenes take place and the coroner is betrayed into utterances which in calmer moments he probably regrets. Towards the close of the adjourned inquest under comment he is reported to have said that "It ought to be clearly understood that England was not going to be the only country in which pathologists were not employed." Does this mean that Mr. Troutbeck intends to reform England and to amend its Coroners Act without the aid of Parliament? The utterance quoted makes no reference to legislative interference. Has any-one ever suggested that pathologists should not be employed or, indeed, that they are not employed already where it is desirable that they should be? It has been said many times in the columns of THE LANCET that their employment, as Mr. Troutbeck employs them, is not sanctioned by the Act of Parliament under which he exercises his powers and by which alone he has authority to offer the payment of fees to witnesses at inquests. It has also been said that any alteration which may be made in the existing system must be made by the legislature, after the views of those who can speak with authority from a medical point of view have been heard and not by the act of a coroner or of a county council deliberately ignoring the law.

Liquozone.

Dr. W. Wynn Westcott, coroner for the North-Eastern district of the County of London, held an inquiry at Stoke Newington on May 26th into the death of an infant who had been dosed with liquozone. The father of the child said that his wife obtained a free bottle of liquozone, and that the deceased child having had half a teaspoonful out of it on Thursday, Friday, Saturday, and Sunday died at noon on Tuesday. Dr. F. J. Smith gave evidence that the child had come to his death through taking liquozone and the inquiry, which was adjourned until next Monday, June 5th, was described by a solicitor on behalf of the British Liquozone Company as being of vital importance to that company. We should think it was, especially as a second child who had been similarly treated has, we understand, since died. Liquozone, as our readers should know,[1] is a solution of sulphurous acid and if the British Liquozone Company recommends its imbibition for diseases of all sorts the company will have a good deal to answer for.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bath Urban District.—Dr. W. H. Symons thinks that pulmonary tuberculosis should be compulsorily notifiable but that the notification should be confidential. He suggests, however, that sufferers from this malady should be exempt from the operations of the Infectious Diseases (Prevention) Act. In our view it is of more importance that this disease should, if notifiable, be exempt from the penal clauses of the Public Health Act, 1875, and it was, we believe, only under these conditions that Parliament allowed the proposal for compulsory notification in Sheffield to become law. Section 45 of the Sheffield Corporation Act, 1903, provides that "no provisions contained in any general or local Act of Parliament relating to infectious disease shall apply to tuberculosis of the lungs or proceedings relating thereto under this section." Dr. Symons gives some interesting particulars relative to the open-air treatment provided by the board of guardians at Bath. He states: "Most of the cases notified to me are too far gone to be permanently restored to the ranks of the workers by a few weeks' open-air treatment, but they are taught how to treat themselves and how to live without being centres of infection." He then adds: "Dr. Craddock reporting to board of guardians states that since the open-air treatment was adopted at the workhouse Oct. 15th, 1903, to the present time 67 cases have been admitted. Of these, ten have been discharged cured, 22 had left while under treatment, 14 are still under treatment, and 21 have died; most of those who died were in a hopeless condition when admitted. The average cost of treatment is 15*s.* per week and the average stay in the infirmary 163 days for those who were cured; the average of all cases 60 days."

Borough of Aston Manor.—By way of reducing the chances of "return" cases of scarlet fever in connexion with the borough isolation hospital Mr. F. H. May endeavours to separate the acute and complicated cases from the convalescent and uncomplicated and, moreover, to give to each patient even a greater cubic space than the 2000 feet laid down by the Local Government Board. In addition to these precautions he also recommends the parents "to quarantine" their children on discharge from hospital for a period of at least a month before they are allowed to mix with the rest of the family at home. This appears to us to be somewhat a counsel of perfection and one which in the homes of the poor is not very likely to be carried into effect. If the domestic circumstances were such as to necessitate the removal of the case to hospital in the first instance when the patient would be confined to bed it is extremely unlikely that a healthy child could be properly "quarantined" for a month in the same house. Probably a suggestion that the patient should not at once be put into a bed with a susceptible child would meet the difficulty and this is a practice which has been adopted at the London Fever Hospital for very many years.

---

[1] THE LANCET, May 13th, 1905, p. 1309.

County Borough of Blackpool.—Dr. F. J. H. Coutts utters a warning relative to the indiscriminate dispatch of consumptive patients to Blackpool. He observes that although early cases where there is no marked breaking down of lung tissue do well advanced cases with cavities are unable to stand the bracing climate and strong winds of Blackpool and grow rapidly worse. This suggestion as regards the need for discrimination in the selection or tuberculous patients might also with advantage be applied to sanatoriums. Not all patients do well at a sanatorium in an elevated and relatively exposed situation, whereas some patients make progress when sent from those elevated situations to an institution less exposed. Potted shrimps preserved with boric acid appear to have a large sale in Blackpool and in one instance this drug was found in an amount equivalent to 70 grains to a pound, which is much in excess of that necessary to preserve these shrimps, even in very hot weather. It is, indeed, debateable whether it is necessary to add any preservative whatever save in the case of Dutch shrimps which are sold as English. There were three cases of anthrax among cattle in the neighbourhood of Blackpool during 1904 and the circumstances connected with the cases demonstrated how very easy it is under existing conditions to send the meat of animals dead from anthrax to the butchers. In one case it was found that the milk of an infected cow was actually received in Blackpool on the day prior to the death of the animal and in another case the inspector on going to a farm at which a death from anthrax had taken place, or where an animal ill from the disease had been slaughtered, found a cart bearing the name of a Blackpool butcher ready to remove the carcass. On inquiring for the viscera of the animal the spleen was found to be missing and there had apparently been no time to procure another spleen to replace this diseased organ. These cases of anthrax gave rise to the death of a man who had helped to dress one of the carcasses and to an attack of malignant pustule in the case of two persons who had been brought in contact with the diseased tissues.

Borough of Kingston-upon-Thames.—Mr. H. Beale Collins expresses the opinion that with regard to pulmonary tuberculosis the great safeguard is to render the body resistant to the germ by physical training, by an open-air life, by rational food, and, above all, by strict temperance. He advocates, however, the restriction of spitting and the disinfection of houses in which tuberculous patients have died.

Chesterfield Rural District.—Dr. Herbert Peck reports that several cases of lead poisoning were brought to his notice during 1904 and he found on examination that they were genuine cases caused by the "plumbo-solvent" action of the public water-supply. Apparently the water shows no acidity when tested with lacmoid solution but it is clear that the passage of the water through lime does not suffice to counteract its "plumbo-solvency." The addition of sodium carbonate is, as Dr. Peck suggests, clearly indicated.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8641 births and 4371 deaths were registered during the week ending May 27th. The annual rate of mortality in these towns, which had been 15·4, 15·0, and 14·4 per 1000 in the three preceding weeks, rose again to 14·6 per 1000 last week. In London the death-rate was 14·6 per 1000, and it also averaged 14·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·2 in Hornsey, 7·2 in Willesden, 7·5 in King's Norton, 8·8 in West Hartlepool, 9·0 in Walthamstow, and 9·3 in East Ham, in Handsworth (Staffs), and in Cardiff; the highest rates were 18·9 in Liverpool, 19·8 in Merthyr Tydfil, 20·0 in West Bromwich, 20·4 in Rhondda, 20·5 in Wigan, and 20·8 in Smethwick. The 4371 deaths in these towns last week included 413 which were referred to the principal infectious diseases, against 469, 401, and 442 in the three preceding weeks; of these 413 deaths, 152 resulted from measles, 133 from whooping-cough, 38 from diphtheria, 37 from diarrhœa, 30 from scarlet fever, 23 from "fever" (principally enteric), but not any from small-pox. In Croydon, Hornsey, Brighton, Norwich, Rochdale, Burnley, York, Swansea, and in six other smaller towns no death from any of the principal infectious diseases was registered; while the highest death-rates from these diseases were recorded in Hanley, West Bromwich, Smethwick, Coventry, Warrington, Middlesbrough, Stockton-on-Tees, Tynemouth, Rhondda, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Bristol, West Bromwich, Smethwick, Warrington, Sheffield, Stockton-on-Tees, Rhondda, and Merthyr Tydfil; from whooping-cough in Tottenham, Hanley, Smethwick, Aston Manor, Grimsby, Bradford, Hull, Tynemouth, and Rhondda; and from diarrhœa in Wolverhampton. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns. No fatal case of small-pox was registered last week in any of the 76 large towns. The number of small-pox patients remaining under treatment in the Metropolitan Asylums Hospitals, which had been 17, 17, and 15 at the end of the three preceding weeks, had further declined to ten at the end of last week; one new case was admitted during the week, against four, two, and three in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2152, 2177, and 2211 at the end of the three preceding weeks, had declined again to 2200 at the end of last week; 312 new cases were admitted during the week, against 235, 319, and 319 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 256, 251, and 226 in the three preceding weeks, further fell to 218 last week, but were 30 above the number in the corresponding period of last year. The causes of 54, or 1·2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Bradford, Hull, Newcastle-on-Tyne, and in 43 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Smethwick, Nottingham, Liverpool, Blackburn, Preston, Sheffield, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·0, 19·5, and 16·7 per 1000 in the three preceding weeks, rose again to 18·1 per 1000 during the week ending May 27th and was 3·5 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15 4 in Leith and 15·8 in Paisley to 21·0 in Dundee and 21·3 in Perth. The 606 deaths in these towns included 30 which were referred to measles, 24 to whooping-cough, seven to diphtheria, seven to diarrhœa, three to scarlet fever, and three to "fever." In all 74 deaths resulted from these principal infectious diseases last week, against 67, 83, and 76 in the three preceding weeks. These 74 deaths were equal to an annual rate of 2·2 per 1000, which was 0·8 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 16, 32, and 26 in the three preceding weeks, rose again last week to 30, of which 21 occurred in Glasgow and seven in Edinburgh. The deaths from whooping-cough, which had been 30 and 25 in the two preceding weeks, further declined to 24 last week, and included 10 in Glasgow, five in Edinburgh, and four in Greenock. The fatal cases of diphtheria which had been four, six, and three in the three preceding weeks, rose again last week to seven, of which five were registered in Edinburgh and two in Glasgow. The deaths from diarrhœa, which had been 15, nine, and 19 in the three preceding weeks, declined again to seven last week, and included three in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been three, four, and two in the three preceding weeks, rose again last week to three, and included two, one of which was a case of typhus, in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 132, 108, and 83 in the three preceding weeks, rose again last week to 107, and were 22 in excess of the number in the corresponding period of last year. The causes of 21, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·0, 23·7, and 19·5 per 1000 in the three preceding weeks, further declined to 18 9 per 1000 during the week ending May 27th. During the past four weeks the death-rate has averaged 21·0 per 1000, the rates during the same period being 14·5 in London and 16·9 in Edinburgh. The 138 deaths of persons belonging to Dublin registered during the week under notice were four below the number in the preceding week and included four which were referred to the principal infectious diseases, against eight, eight, and six in the three preceding weeks; of these, one resulted from measles, one from diphtheria, one from whooping-cough, and one from "fever," but not any from small-pox, scarlet fever, or diarrhœa. These four deaths were equal to an annual rate of 0·6 per 1000, the death-rates last week from the principal infectious diseases being 1·4 in London and 3·1 in Edinburgh. The 138 deaths in Dublin last week included 27 of children under one year of age and 37 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a decline from the respective numbers recorded in the preceding week. Seven inquest cases and five deaths from violence were registered; and 61, or more than two-fifths, of the deaths occurred in public institutions. The causes of seven, or more than 5 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon J. M. France to the *Emerald* to join the *Carnarvon* on relief. Staff Surgeons: H. P. Jones to the *President*, for three months' course at Adelaide Hospital, Dublin; N. I. Smith to the *Hermes;* and R. H. Mornement, to R.M.A. Headquarters, Portsmouth. Surgeons: W. N. Horsfall to the *Ariadne;* P. D. Ramsay to the *Juno;* B. Scribner to the *Shearwater;* and F. F. Mahon to the *Pioneer*.

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—Hugh Prideaux Turnbull, Walter Byron Maurice, Sidney Roach, Eustace Arkwright, Walter Kempson Hopkins, Harold Edgar Fryer, Samuel Conner, and Robert Harry Mornement (dated May 25th).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel H. S. McGill is appointed to the Eastern Command for duty.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement from the service of the undermentioned officer:—Colonel Charles Little (dated Feb. 12th, 1905).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Supernumerary Lieutenant (Honorary Lieutenant in the Army) J. W. Hopkins to be Captain and to remain seconded (dated Feb. 26th, 1905).

IMPERIAL YEOMANRY.

Yorkshire Dragoons (Queen's Own): Surgeon-Captain P. B. Mackay to be Surgeon-Major (dated May 27th, 1905).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Banff: Surgeon-Lieutenant N. Davidson resigns his commission (dated May 27th, 1905). *Rifle:* 3rd Lanarkshire: Surgeon-Lieutenant A. Roxburgh to be Surgeon-Captain (dated May 27th, 1905). 1st Surrey (South London): Captain and Honorary Major Charles Joshua Joseph Harris (late the Pembroke Royal Garrison Artillery (Militia)) to be Surgeon-Lieutenant (dated May 27th, 1905). 2nd Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant W. M. Mackay to be Surgeon-Captain (dated May 27th, 1905).

ARMY MEDICAL SERVICE.

An examination of candidates for not less than 40 commissions in the Royal Army Medical Corps will be held on July 27th and following days. Applications to compete should be made to the Secretary, War Office, 68, Victoria-street, London, S.W., not later than July 17th, on which date the list will be closed. Candidates who are over the regulation limit of age at the date of the examination will be permitted to deduct from their actual age any period of service in the field after Oct. 1st, 1899, that they could reckon towards retired pay and gratuity if such deduction will bring them within the age limit. The presence of candidates will be required in London from July 25th.

THE MEMORIAL TO THE ROYAL ARMY MEDICAL CORPS.

As we announced briefly last week, His Majesty the King unveiled the monument to the officers and men of the Royal Army Medical Corps who fell in the Boer war. This ceremony was appropriately performed on Empire Day, May 24th, the anniversary of the birth of Queen Victoria. After witnessing a sham fight, His Majesty, who was accompanied by the Duke of Connaught, drove to the headquarters of the Royal Army Medical Corps at Aldershot, where he was received by Bishop J. Taylor Smith (Chaplain-General), the Rev. P. F. Raymond (Chaplain to the Forces), Surgeon-General A. H. Keogh, C.B. (Director-General of the Army Medical Service), Surgeon-General Sir W. D. Wilson, Colonel A. T. Sloggett, C.M.G., Lieutenant-Colonel G. M. Robinson (commanding the R.A.M.C. Depôt), Lieutenant-Colonel W. Babtie, V.C., C.M.G., Lieutenant-Colonel R. J. S. Simpson, C.M.G., Major F. J. Greig, Major R. J. C. Cottell, Mr. Goscombe John, the sculptor, Mr. Weir Schultz, the architect, Surgeon-General W. H. Macnamara, C.B., C.M.G., Lieutenant-Colonel J. M. Irwin, and Colonel C. E. Heath. The following address was then read by Surgeon-General Keogh: "May it please your Majesty,—The memorial, which your Majesty is graciously about to unveil was erected by the officers, warrant officers, non-commissioned officers, and men of the R.A.M.C. to the memory of their comrades who were killed in action or died of disease in the South African war. In this memorial 21 officers and 293 non-commissioned officers and men are commemorated." Following a prayer, read by the Chaplain-General, the King unveiled the memorial and addressing those present said: "I have had great pleasure to-day in unveiling at your wish this memorial in remembrance of those gallant officers and men of the Royal Army Medical Corps who fell during the recent campaign or by disease. I am well aware of the valuable services which medical officers rendered to their country and to the sick and wounded during that arduous campaign and I feel sure that they will often now and in the future excel, if it is possible, in those duties. It has given me great pleasure, and, I may say, melancholy satisfaction, to unveil this monument to-day."

REGIMENTAL HOMES AT BODMIN.

The foundation stone of two Regimental Cottage Homes for men of the 1st and 2nd Devon and Cornwall Light Infantry has just been laid at Bodmin (Cornwall) by the Bishop of Truro in the presence of a large gathering. The houses, which will accommodate two men of the regiment with their families, will be erected at a cost of £1250, which sum was subscribed during the recent South African war. The site has been given by Viscount Clifden.

THE WAR IN THE FAR EAST.

The attention of the whole civilised world may be said to be concentrated at the present time on the stupendous events that have been taking place in the Korean Straits involving the destruction of the Baltic fleet and a naval disaster on an altogether unprecedented scale to the Russians. It is almost impossible to refrain from making some allusion to Admiral Togo's achievements, but such matters do not come within the purview of the medical journalist. We may all be permitted to hope, however, that an end is approaching to this war, for it is terrible to think of the enormous sacrifice of life and of the millions of money that are lost in a very brief time in a naval battle. Even apart from the marvellous success of the Japanese in this war, which has throughout been planned and conducted by them with what may be rightly termed scientific precision, it may be truly said that there is nothing to compare with the recent growth, progress, and development of Japan in the history of the evolution of nations. It is, of course, hopeless to expect at the present moment any account of the naval medical preparations and arrangements on the part of the belligerent fleets.

As regards the land forces there is nothing important to be chronicled. Continuous heavy rains are reported in Manchuria and serious military operations are stated to be greatly impeded owing to the state of the roads.

Prince Vassiltchikoff, executive officer of the Red Cross Society at the front, telegraphs that the chief want of the society's service is in means of transport and he pleads that all efforts should be directed to supplying two-wheeled carts and horses. He recommends a trial to be made of the carrying system of the Japanese.

The *Army and Navy Gazette* states that the German Emperor has sent to Lieutenant-Colonel W. G. A. Bedford, C.M.G., R.A.M.C., the officer in charge of the Military Hospital at Gibraltar, four pictures representing the several types of the German Cavalry and Infantry in different periods. These pictures are to be hung in the hospital as a souvenir of His Majesty's recent visit to the institution.

Correspondence.

"Audi alteram partem."

THE NATURE OF DIABETES MELLITUS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 27th, p. 1459, Dr. Arnold Lorand replies to one point raised by Dr. W. C. Bosanquet in his interesting Goulstonian lectures on the Nature of Diabetes Mellitus. I have been hoping that someone would discuss some of the more general questions involved, for it seems to me that certain of Dr. Bosanquet's hypotheses present serious difficulties from the physiological standpoint. In discussing alimentary glycosuria he says:[1] "It is fairly established that a certain proportion of starchy food is converted into sugar in the alimentary canal." And further on:[2] "Over-production of sugar may depend on some digestive irregularity whereby more sugar than normal is poured into the blood." Surely the first quotation understates the facts. In what form other than sugar *is* the starchy food absorbed? Is it not the case that the whole of the absorbed carbohydrates (with the possible exception of galactose and lævulose) pass into the portal vein as dextrose? It is difficult to see how some digestive irregularity could increase the normal process of absorption. Even if "it is not impossible that the lungs may act as the mechanism in liphæmia for removing excess of fat from the blood, a process of oxidation taking place within them" (p. 1055), all the evidence we possess is strongly against such a hypothesis. The seat of oxidation is the tissues and not the lung capillaries, as Ehrlich showed by his methylene blue experiment. It is interesting to find that Dr. Bosanquet has noted conditions in which the alveolar structure of the pancreas is lost in certain areas and approximates to that of the cell islets. He concludes this is a post-mortem change but Dale has been able to produce similar changes experimentally by the injection of secretin, which points to their having some definite significance.

Arguing from the inhibition of salivary secretion from fear, Dr. Bosanquet suggests an analogous cause for diabetes from shock in the drying-up of the internal secretion of the pancreas. But in this gland any nervous control for secretion is still to be proved and Bayliss and Starling have shown that its activity can be evoked by purely chemical stimuli under conditions excluding all nervous factors. He reviews the suggestions that have been made as to a joint action of the pancreas with some other organ in the regulation of sugar metabolism. But he does not discuss the muscles, which in view of the importance of carbohydrate as a source of energy might play some part in this. Otto Cohnheim found that whereas pancreatic and muscle extracts separately have no glycolytic action mixtures of such extracts have a powerful action; he concludes that muscle contains a zymogen or inactive ferment which is activated by the internal secretion of the pancreas. We can hardly admit that "the peculiar effect of the secretion of the suprarenal body in producing glycosuria must be attributed to its action on the internal secretion of the pancreas" (p. 1053). Von Mering and Minkowski found that removal of the pancreas in ducks and geese failed to produce diabetes, yet Noel Paton was able to produce glycosuria in these animals by injection of adrenalin.

Perhaps the most novel point in the lectures is the view that fat is the source of the sugar in the urine. Since carbohydrate is a fat-forming food there is certainly no *a priori* reason against the reverse change occurring. But in support of his hypothesis he mentions the liphæmia and the accumulation of fat in the skin, kidneys, and muscles in diabetes. I confess I fail to see how if the fat is rapidly disintegrating into sugar and acetone it can accumulate in the tissues. The definite ratio between the excretion of carbon and nitrogen, which has been observed both in the disease and experimental diabetes, is surely best explained by the origin of sugar from proteid. That proteid can give rise to sugar is shown by the fact that phloridzin will cause glycosuria in starving animals in which there is no fat left. One can quote Dr. Bosanquet against himself on this point: "We must not lightly suppose the existence of two separate chemical reactions leading to one and the same result until it is shown that neither one alone is sufficient to explain the phenomenon." Reversing his question it may be asked: "If some of the sugar is formed from proteid, may not it all be thence derived?" Lépine's statement (uncorroborated so far as I am aware) that the sugar in the urine may be too great to have come from the food or the proteid tissues seems a slender basis on which to build up the contrary hypothesis.

I am, Sirs, yours faithfully,
W. LANGDON BROWN.

Finsbury-square, London, E.C., May 27th, 1905.

THE SANATORIUM TREATMENT OF CONSUMPTION: IS IT WORTH WHILE?

AN ANSWER FROM THE DURHAM COUNTY SANATORIUM.

To the Editors of THE LANCET.

SIRS,—On April 30th last the committee of the above sanatorium instituted its annual inquiry through Dr. J. Gray, its medical officer, as to the condition of all the patients who had been treated in, and discharged from, the sanatorium during the previous five years. The following is a summary of the present condition of the patients.

1. *Cases who had on admission consolidation only of the lungs, i.e., early cases.*—In 1900–01 16 cases were treated; 14 were enabled to return to work; of these 12 are still at work after more than four years and 4 are dead. In 1901–02 30 cases were treated; 23 were restored to work, 17 are now at work and have been so between three to four years, 5 are at home, and 8 are dead. In 1902–03 41 cases were treated and 30 had their working power restored; 23 of these have been following their occupations between two and three years, 4 are at home, and 14 are dead. In 1903–04 59 cases were treated; 46 were restored to work (and have been at work between one and two years), 11 are at home, and 7 are dead. In 1904–05 75 cases were treated; 57 were restored to work (all of these are still at work), 15 are at home, and 3 are dead. Totals: Of 221 early cases treated 170 were restored to the ranks of workers, 150 are still at work, 35 are at home, and 36 are dead.

2. *Advanced or cavity cases.*—In 1900–01 20 cases were treated and 9 returned to work; 3 are, and have been, at work more than four years, 1 is at home, and 16 are dead. In 1901–02, of 25 cases treated 12 were returned to work; 4 of these have been at work between three and four years, 4 are at home, and 17 are dead. In 1902–03, of 38 cases treated 23 were enabled to return to work; 9 have been at work between two and three years, 11 are at home, and 18 are dead. In 1903–04, of 39 cases treated 16 were restored to work; 10 of these have been at work between one and two years, 7 are at home, and 22 are dead. In 1904–05 37 cases were treated and 14 were enabled to work; all of these are still at work, 18 are at home, and 5 are dead. Totals: Of 159 cavity cases 74 were restored to the ranks of workers; 40 are at work, 41 are at home, and 78 are dead.

Remarks.—Practically all the patients (men and women) belong to the working classes. A very large percentage went back to insanitary and poor homes; hence relapses, especially among the advanced cases, are common and to be expected. Almost all the cases had definite physical signs of lung disease, more than half had disease in both lungs, and many were complicated cases; all but a very few were unable to work on admission. Our great difficulty has been to get working-class patients to apply in the initial stage of the disease and to find them suitable work afterwards. The average age of the patients was about 28 years, the average stay in the sanatorium was 15 weeks, the average gain in weight was about 18 pounds, and the average cost per patient per week was approximately 25*s*. Our sanatorium has been practically self-supporting from the beginning and we have enabled the working men of this county to provide for themselves and those over the age of 15 years depending upon them sanatorium treatment, should they require it, at the nominal cost of 1*s*. per year per man. We are fully satisfied with the excellent results obtained.

[2] THE LANCET, April 22nd, 1905, p. 1058.

I am, Sirs, yours faithfully,
W. ROBINSON,
Chairman of the Committee.
May 27th, 1905.

MORPHINE AND CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—It has been recognised almost from the introduction of chloroform by those intimate in its administration that patients who were under the immediate influence of morphine or opium required less of the vapour of chloroform and a shorter time than those who were not under its benign influence to produce insensibility. In fact, by some the preliminary administration of morphine has been recommended, and although I am personally adverse to it as a point of routine it is not unreasonable to admit that some patients would be benefited by it. As a matter of experience it is not advisable to give it before the administration of nitrous oxide gas, and any medical man who happens to know that his patient is taking opium at the time of an intended administration should inform the administrator for the sake both of the patient and all concerned. Through this inadvertence one of my patients determined never to have "gas" again.

Some years ago I was requested by the late Dr. J. Braxton Hicks to administer chloroform to a patient who had been cured of the habit of the *piqûre* to the amount of 23 grains of morphine in the day. Although I anticipated some incidental difference there was none and unless I had known I should have classed the case as normal. A little time ago I was asked by Dr. H. H. Murphy of Twickenham to administer chloroform to a patient under cure in a home for the same trouble. It was not known to what extent the poor fellow had used the syringe, but he had been reduced whilst under treatment to 41 grains of morphine in the 24 hours, and it was whilst under this amount that I gave him the vapour of chloroform. There was nothing to observe except, as in the former case, an entire absence of the falsely called "excitement stage" and I was more occupied with the fact that he was fat and therefore might show some abnormality. He suffered from three rather extensive abscesses. The first case, it will be seen, was cured of the habit and the second had been much reduced in quantity. When it is supposed to represent 287 grains of opium, I think the last case deserves recording. I am, Sirs, yours faithfully,

TOM BIRD,
Consulting Anæsthetist to Guy's Hospital.
Brook-street, W., May 23rd, 1905.

GALL-STONES AND CANCER.

To the Editors of THE LANCET.

SIRS,—The late Dr. G. R. Slade, in a paper entitled "Gall-stones and Cancer," and published shortly before his death in THE LANCET of April 22nd, 1905, quoted cases to show that many of the thickened gall-bladders found in association with gall-stones are carcinomatous. The first thickened gall-bladder which I had an opportunity of examining after having read Dr. Slade's interesting paper proved to be carcinomatous. The patient was admitted into this hospital under the care of Mr. Stanley Boyd, to whom I am indebted for permission to record the case. The case is that of a woman, aged 40 years, who had had symptoms suggesting the presence of gall-stones for 12 months. She had lost flesh considerably since her arrival in England from abroad but she states that her visits to England have always been accompanied by loss of weight. At the operation two gall-stones were found impacted in the neck of the gall-bladder which was kinked. The gall-bladder was removed, not because it was thought to be carcinomatous but because cholecystectomy was considered to be the most satisfactory method of dealing with the case. The gall-bladder was uniformly thickened to a moderate degree. The liver showed no sign of secondary growths. Microscopical examination of the wall of the gall-bladder revealed the presence of columnar-celled carcinoma.

I am, Sirs, yours faithfully,
H. A. T. FAIRBANK,
Surgical Registrar.
Charing Cross Hospital, May 31st, 1905.

CANCER BODIES AND REPRODUCTIVE TISSUES.

To the Editors of THE LANCET.

SIRS,—May I draw the attention of Professor J. B. Farmer and his colleagues to the fact that in my Erasmus Wilson lectures on the General Pathology of Tumours,[1] I drew attention to the close resemblance between cancer bodies and the archoplasmic structures found in the spermatocytes of the guinea-pig and at the lectures I showed lantern slides in illustration of this resemblance. My attention was drawn to this subject by the paper by Borrel.[2] I did not publish my observations in more detail at the time because I was hoping to continue my researches on the cytology of tumours and publish them when they were more complete. Unfortunately, I left Leeds soon after I delivered the lectures and have not had time since then to continue my work on the subject. I am, Sirs, yours faithfully,

CHARLES POWELL WHITE.
St. Thomas's Hospital, S.E., May 27th, 1905.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

(FROM ONE OF OUR SPECIAL COMMISSIONERS.)

PRIVATE HOSPITALITY.—THE BRITISH LADIES.—LUNCH TO THE MEDICAL PRESS.

A FEW words yet remain that should be added to the lengthy description already published in THE LANCET of the great reception given in Paris to the British physicians and surgeons. Without attempting to notice the whole series of private receptions held by French medical men in their own homes, it is necessary that fuller mention should be made of the hospitality by the president and the vice-president of the reception committee. The former, Professor Bouchard, being anxious to invite everybody concerned, was compelled to hire a large hall near the Champs-Elysées known as the Salle Washington. Then, as there were many dinner parties on the same evening—namely, May 11th —the reception did not commence until after 10 o'clock. The "*tout Paris*" of medicine was there as was nearly every British guest. The big hall was very crowded by animated, interested, and interesting guests. On the same evening Dr. Lucas-Championnière, the vice-president, had entertained to dinner at his private residence Sir William and Lady Broadbent and a number of other British visitors. On the following day he gave another dinner. The British visitors had thus an opportunity of seeing something of the domestic life and household management which in Paris differs considerably from English customs. But, above all, they had an insight into the artistic refinements of that life which, combined with the presence of unfailing amiability, and the absence of any sort of affectation or stiffness, make Parisian society exceptionally attractive.

In this respect we have been especially requested by several British ladies who accompanied their husbands on this ever-memorable visit to say a few words on their behalf. They are desirous to make known how deeply touched they have been by the extraordinary attention and kindness bestowed upon them by the French ladies. This was not a question merely of parties, dinners, and entertainments, but of daily and indeed hourly watchfulness and friendship; of advice and help or guidance constantly given, however petty the detail or the incident by which it was evoked. It was not so much the brilliant entertainment as the sisterly welcome which the British ladies found awaiting them that has produced so deep an impression and evoked lasting gratitude. The British ladies were never allowed time for a single dull moment. Those among them who could not speak French were allotted lady hostesses who could speak English and were never left alone or without attention. Minute details were not neglected. From the first, and though strangers in a strange land, the British ladies were made to feel thoroughly at home. With unfailing foresight and sisterly concern their French hostesses saw to all their requirements and were ever in attendance ready to escort their British visitors everywhere and at all moments. Then there were all manner of pretty compliments and flowers and the delicate bonbons for which Paris is so renowned forthcoming at propitious moments. Altogether the British ladies who participated in the visit to Paris and the subsequent excursions find it difficult to express their appreciative gratitude and have asked us to help them to give voice to their feelings.

---

[1] THE LANCET, Feb. 15th (p. 423) and 22nd (p. 491), 1902.
[2] Annales de l'Institut Pasteur, February, 1901.

Another private entertainment to which allusion may be made was the lunch given on May 13th by Dr. R. Blondel in honour of the medical press. On this occasion the English custom of toasts was introduced and Dr. Blondel rose at dessert time to propose "The Representatives of the Medical Press" which had so largely contributed to bring about the *entente cordiale* between France and England. He referred especially to THE LANCET and the *British Medical Journal* and regretted that the editors of those journals were unfortunately unable to be present that evening. He desired to thank them for having helped in the work of organising the International Association of the Medical Press. The British medical press owed its strength to the fact that it consisted of so few journals, whereas in other countries the influence of the medical press was weakened through being scattered over so many and therefore necessarily smaller publications. However, all had alike contributed to the work of [illegible] fore raised his glass and drank to the medical press and to the long continuance of friendship between the two countries. Mr. Adolphe Smith responded. He pointed out how in politics the cause of peace and in literature the cause of science were indebted to Dr. Blondel. To-day much was said about the closer and more friendly relations existing between England and France; but Dr. Blondel was drawing together all the civilised nations of the world by uniting in one vast organisation the medical press not only of England and France but of all countries. By association a better understood and more generally accepted sense of what was right and honourable would be engendered and cultivated. A very great debt of gratitude, therefore, was due to Dr. Blondel for the initiative he had taken and also to Madame Blondel for the way in which she had helped in the good work, rendering her husband's task more easy by the gracious welcome which she gave to all his friends and co-workers. He therefore drank to Dr. Blondel, the general secretary of the International Association of the Medical Press, and to Madame Blondel.

Dr. G. H. F. Nuttall, editor of the *Journal of Hygiene*, said a few words concerning the wonderfully hearty reception which the British visitors had received. Then he alluded to the forthcoming International Congress on Tuberculosis and expressed the hope that there would be a strong British contingent. He was pleased to think that the press had helped to bring about cordial friendship between the two peoples.

Mr. L. E. Creasy, editor of the *Clinical Journal*, and Dr. Leonard Williams, editor of the *Journal of Balneology and* [illegible] s. Several Frenc[illegible] meet their Britis[illegible] bert Robin, edito[illegible] Dr. Emile Boix, editor of the *Archives Générales de Médecine*, a journal that is junior to THE LANCET by only two years; Dr. F. Galezowski of the *Recueil d'Ophthalmologie*; and Monsieur F. Alcan, the medical publisher.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University Intelligence.

THE Lord Chancellor this year accepted the invitation of the Guild of Undergraduates to become its warden. He attended a fortnight ago to deliver his address which was listened to by a large [illegible] the Chancellor of th[illegible] Exchequer, Lord Aveb[illegible] M.P. After paying a [illegible] after saying how fort[illegible] itself in having so distinguished a man for its chancellor he reminded his audience that in early days the word "university" meant an exactly different thing from what it meant now. What it then meant was a place where everyone might go; whereas Mr. Chamberlain's definition of a modern university was that it was a place where everything was taught. The leading line taken in the address was that English universities must rival more the continental universities in teaching the application of new discoveries to trade processes. He lamented, however, the fact of there being no chair of Greek in the University. Mr. Chamberlain, in proposing a vote of thanks to the Lord Chancellor for his address, shared in his regret that there was still no such chair but said that the chief work of their University was the teaching of science and that the buildings now rising would, when completed, constitute opportunities for such work that no university has, or has had, in this country before and that they will be on a scale and of a quality unequalled by any university in America or on the continent.—Dr. R. Saundby, professor of medicine in the University, began a short time ago a course of four lectures to students and practitioners on Medical Ethics, a subject upon which he is an acknowledged authority. He pointed out that medical ethics went back further than the Hippocratic oath, that they were known in the time of Hammurabi, King of Babylon, more than 2000 years B.C. The relations of the medical man to his patient, to the legal authorities, and to his fellow medical men have all been admirably and lucidly explained. The lectures, two of which have still to be delivered, have been attended by large and appreciative audiences.

The Education Rate.

The education rate, which has been steadily rising and which of late years has increased with astonishing rapidity, is occasioning considerable anxiety. This year the total sum asked for was £209,710 but upon its being sent back for revision the demand was reduced to £204,901—a rise, however, of £31,000 over that of the previous year. The increase in expenditure is attributed to payments made by the committee to the University, to its being responsible for the technical school expenditure, to the foundation of special schools for the blind, deaf, cripples, and feeble-minded, and to the increased salaries which are now being paid to teachers.

The Feeble-minded.

A site—Monyhull Hall, King's Heath—has been purchased by the joint committee of the Birmingham, Aston, and King's Norton Poor-law authorities for the accommodation and treatment of feeble-minded and sane epileptics. It occupies 128 acres and has cost £13,500. The importance of founding colonies for such unfortunates where they may be permanently looked after was well evidenced in the annual report of the Birmingham Laundry and Homes of Industry for Feeble-minded Young Women. It was there stated that of the 52 girls who had left and whose "after history" was traced only two or three seemed to be doing well and earning their own living.

Lunatic Asylums Committee.

Some dissatisfaction has arisen over the communication from the lunatic asylums committee to the local boards of guardians giving notice that from July 1st the charge for patients chargeable to the boards will be increased from 10*s.* 6*d.* to 11*s.* 1*d.* a week per patient. The cause of the rise is said to be the expenditure of Hollymoor Asylum.

The Health of Birmingham.

The report of the medical officer of health for the first quarter of the present year has just been issued. It shows a low birth-rate of 31·6 per 1000, as compared with 33·5 for the first quarter of 1904. The death-rate of 16·8 per 1000 is the lowest on record. For the same period last year the rate was 21·4. Eight cases of small-pox were notified; they were all traceable to one lodger, so that there has only been one importation. Small-pox has again reappeared in the city after a brief freedom from it. There are at present four patients suffering from it in the isolation hospital.

May 30th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Re-housing Problem: Health of Liverpool.

Mr. F. H. Tulloch, Local Government Board inspector, attended at the municipal offices on May 23rd to examine the Liverpool corporation's schemes for the erection of new artisans' dwellings in four Liverpool streets. Mr. Cripps, assistant solicitor to the corporation, explained that the schemes submitted were for fulfilling the obligations of the corporation under the several housing clauses and provisional orders. The policy of the corporation had been not to pull down any buildings before erecting others for the dispossessed tenants. Some houses were demolished in Christian-street without a scheme for re-housing being submitted to the Local Government Board. As this was an oversight, and although thereby the corporation was liable to considerable penalty, he asked the Board to exculpate it because a street improvement had been effected and there were plenty of vacant houses even at the present time in the half-mile radius. Out of 1720 dwellings built by the corporation 180 were vacant. A return prepared at the beginning of the year by the head constable showed 4293 vacant houses in the city, of which 1145 were houses of 5*s.* a week rent and under. This was to be explained by the fact that the electric tram system and cheap fares attracted the labouring class to reside in the suburbs. During the last four years over 2000 of the working-class houses had been built chiefly on the outskirts of the city. The corporation surveyor explained the character of the dwellings proposed to be built in the streets previously mentioned. Dr. A. A. Mussen, the assistant medical officer of health, gave a census return of the vacant houses in the localities in which the schemes were to be carried out. The remarkable fact was that during the past few years the number of common lodging-houses in the city had decreased by 50 per cent. The inspector will in due course report to the Local Government Board, who will decide on the number of dwellings to be erected to re-house dispossessed tenants.—During the past week 511 births and 240 deaths were registered in Liverpool, representing a birth-rate of 36·3 per 1000 and a mortality of 17 per 1000. In the corresponding week of last year the death-rate was 18·4 per 1000. Of 652 cases in the corporation infectious hospitals 488 patients were suffering from scarlet fever and seven from typhus fever. The chairman of the health committee referred at the meeting with satisfaction to the prevailing low death-rate.

Winwick Asylum: Acute and Dangerous Types of Lunacy.

A recommendation that a further sum, not exceeding £30,000, as may be necessary for extras and to complete the asylum buildings at Winwick should be granted out of the asylums fund was contained in the report of the finance committee and laid before the Lancashire Asylums Board at its meeting at Preston. Certain things were left out in connexion with the building operations which had to be done to make the building satisfactory to the committee. The chairman said that the whole cost of the asylum would be about £45,000, which did not appear to be excessive. A letter was read from the Commissioners in Lunacy with reference to allowing Winwick Asylum to be used for acute cases. It stated: "That having regard to the very large number of troublesome, turbulent, and dangerous cases that were found in the asylum at the annual visit in February last, the Commissioners felt unable to withstand any longer the wishes of the board that the asylum should not any longer be reserved for chronic cases." In connexion with this matter the chairman said that it had been agreed that it would be desirable to build an asylum on the villa system and on a cheaper scale something like a workhouse, where chronic cases who were unable to take care of themselves and who were unable to work but did not require the same skilled medical care as acute cases which went to the asylums, should be lodged. It was for the board to consider whether it could not devise a scheme for building a cheaper class of asylum where such patients could be maintained at a much less cost to the ratepayers. Eventually a motion was carried to the effect—

> That as the restriction as to the using of Winwick Asylum for chronic cases only has now been removed it will be desirable to consider the advisability of utilising the proposed site at Whalley for an asylum of cheap construction to accommodate cases other than of the acute and dangerous types.

It was also decided to empower the Whalley committee to communicate with the various boards of guardians on the subject.

Hospital Saturday Fund.

The honorary treasurer has issued the first list of the contributions from the employés of a number of workshops, &c., to the Hospital Saturday Fund, which amounted to £5390 6*s.* 7*d.* The second list will be published on July 3rd.

May 30th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The University of Leeds: Commemoration of the Inauguration.

BY request of the council of the University of Leeds a special number of the *Gryphon*, which is the journal of the University, has been issued in commemoration of the inauguration which took place last October. The special committee which was charged with the responsibility of editorship is to be congratulated on having produced what all will regard as a worthy memorial of a great and important event. In the letterpress we find the address of the Chancellor, Lord Ripon, at the first meeting of the University Court which lays down a high ideal of the work which should be aimed at; following this is a brief account of the first congregation, on which occasion the first honorary degrees were conferred, and the orations delivered by those presenting the graduates are given in abstract. The speech of the Duke of Devonshire, though, as His Grace remarked, "to some extent a departure from the ordinary course of academic procedure," deserves to be given in full as it is. From this speech I quote the following passages: "I observe that in your new constitution as defined by your charter and your statutes a remarkable and exceptional share of the government of this University has been entrusted to the representatives of local authorities in Yorkshire. I believe that in this a wise course has been taken, because it is of the first importance that from the outset a wide popular interest should be taken in the studies and work of this infant University. And I am at the same time sure that the good common-sense which distinguishes Yorkshiremen will lead them to entrust a great share of the direction of the studies and work of this University to those who have qualified themselves for that direction by educational work. I feel sure that they will not desire that the training to be given here shall be of too exclusively a utilitarian character." A brief paper by Professor Miall on the beginnings of the Yorkshire College reminds us that in 1868 a circular was issued by the Yorkshire Council of Education announcing that a college of science was projected. The three first professors were Rücker, Thorpe, and Green. "Such men as these," says Professor Miall, "would make any place of learning thrive." In 1878 the addition of arts professors was followed by a change of name and the Yorkshire College was inaugurated. The Leeds School of Medicine, founded by William Hey in 1831 and for many years a flourishing institution, was in 1884 amalgamated with the college, which was soon afterwards incorporated with the Victoria University. From the pen of Mr. C. G. Wheelhouse, one of the honorary graduates, we have a short paper on medical student life in Leeds 60 years ago. It may be the case that, as he quotes as a heading for his reminiscences, "*Tempora mutantur, nos et mutamur in illis,*" but Mr. Wheelhouse seems to possess the secret of preserving a youthfulness of mind which must be the envy of all. When we read that Mr. Wheelhouse could "fill a volume with memories of those happy and pleasant days" we must echo the feelings of all who know him when we say, "*Cur non?*" Illustrated as it is by views of the University buildings, including, of course, the medical school, and by reproductions of photographs of the chancellor, pro-chancellor, vice-chancellor, dean of the Faculty of Medicine, honorary graduates, members of the Senate, and others, this special number will appeal to all former students of the college and to all who are interested in the future of the University. Succeeding the title page is the following poem from the pen of Mr. Alfred Austin, in whom, as the vice-chancellor said when presenting him for the degree of LL.D., "we delight to honour a poet who, born within the borough of Leeds, has gained the only distinction which the State bestows upon the first and the greatest of the arts."

"Above the glow of molten steel,
  The war of furnace, forge, and shed,
Protectress of the city's weal,
  Now, Learning rears her loftier head;

That Progress may at length descry
  It hath no clue to guide aright,
And, conscious of its blindness, cry
  Unto the Muse, 'More light! More light!'

. . . . .

  Mind must be lord and master still."

The late Mr. George Stamp Taylor.

By the death of Mr. George Stamp Taylor, at the age of 58 years, which occurred on May 25th, Leeds has lost one of the most widely known and highly respected of its medical men. Mr. Taylor was educated at the old Medical School of Leeds and became a Member of the Royal College of Surgeons of England in 1870. Some few years after starting in practice he was threatened with pulmonary tuberculosis and on the advice of Dr. T. Clifford Allbutt he made voyages to Australia and the Cape. His restoration to health was complete and throughout a long and busy professional life of 35 years his fine presence and robust frame seemed strangely at variance with the symptoms of that anxious time. Mr. Taylor was to all outward appearance in his usual good health until about a fortnight prior to his death, at which time signs of serious hepatic disease became manifest and it was seen that the end could not be far off. For many years Mr. Taylor had a very extensive practice both among the working and middle classes, and probably there was no man in Leeds more highly or more deservedly respected by his patients and by his professional brethren. To the latter he stood as a type of all that was best in the general practitioner; unflagging in his care of his patients, scrupulously loyal in his dealings with his neighbours, he commanded the esteem alike of his brother practitioners and of those whose aid he sought in consultation. Mr. Taylor leaves a widow and six children, with whom the deepest sympathy is felt.

May 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Sanitary Condition of Glasgow.

THE report just issued by Mr. Peter Faffe on the operations of the sanitary department of the city of Glasgow during the year 1904 forms very interesting and instructive reading for medical men and others concerned in the improvement of the conditions of living of those who go to make up the greater bulk of the inhabitants of our large cities. The Registrar-General's estimate of the population of Glasgow in 1904 was 798,357. The total deaths in that year amounted to 14,794 and the annual death-rate on this estimate comes out at 18·53 per 1000, in place of 18·405 for 1903. Zymotic disease has not been quite so prevalent. The total cases recorded were 16,333, or 154 less than had to be dealt with in 1903 and 3209 less than in 1902. 5185 cases were treated in the fever hospitals and 11,148 at home. Again measles heads the list with 8348 cases, or more than half the total number. There were 870 cases of small-pox, against 292 cases for 1903 and 460 for 1902. In connexion with the above cases of infectious disease a large amount of disinfecting work was done. The routine method for rooms was fumigation with sulphur or spraying with formalin solution. Bedding and clothing were either washed in the sanitary wash-houses or treated in the vacuum steam disinfector, and 1467 beds were burned in the cremators. In dealing with public nuisances 44,318 cases were investigated during the year. The choking of branch soil-pipes and drains and disrepair of these formed the greatest percentage of the causes, 13,197 cases of this description having been found. Next in order come filthy stairs, closets, and lobbies, 7703; traps of water-closets or sinks choked and out of repair, 6546; and internal walls of dwelling houses in a filthy state, 5648. It is worthy of note that of nuisances in workshops three of the wards of the city contribute a large proportion and it is suggested that this may be due to the admixture there of a considerable alien population in excess of what is found in other wards. The report as a whole shows that the sanitary department of the city has a large amount of work to undertake each year and that it performs its duties thoroughly and with a great measure of success.

University of Aberdeen Medical Society.

At a meeting of the above society on May 26th, Professor J. Theodore Cash presiding, Dr. Ashley W. Mackintosh read an interesting paper on Cerebral Localisation. The extent of the motor areas, he said, had been narrowed down by recent investigation to the Rolandic region, the paracentral lobe, and the bases of the first and second frontal convolutions. In the bases of the first and second frontal convolutions in monkeys were centres for movement of the head alone to one side and of the head and eyes together, and in a case of Jacksonian epilepsy he had been able to demonstrate the possibility of these two centres being present in man. Neurologists were at present not decided as to whether the motor areas were also sensory. Some held that only motor, and no sensory, symptoms resulted from a lesion in the motor area. Clinical evidence was adduced to show localisation of sensation, especially the muscle sense and the stereognostic sense, in the superior parietal convolution. An argument in favour of the sensori-motor idea was that lesions confined to these areas gave motor and sensory phenomena but the difficulty was to be sure that the effect of the lesions was so limited—to exclude the spreading effect of the lesion and hysteria. Was it possible to have paralysis without any lesion of the motor area or of the pyramidal tracts? A lesion cutting off the sensory from the motor centre caused "soul paralysis." Mott and Sherrington had shown by experiments that cutting the posterior roots of the spinal nerves on one side gave complete paralysis on that side without there being any motor lesion and similar cases had been observed in man. The muscles were devoid of spontaneous voluntary movement but could be used for reflex actions such as scratching or in imitation of another's action. In one case the arm was flaccid; there were no reflexes; pain, muscle, and stereognostic senses were lost; the patient could move the arm in imitation or when commanded but rarely spontaneously. All motion was reflex, old sensory impressions being called up to start motion. The motor centres were also stimulated by the visual and the auditory centres, hence the movement in irritation or on command. Regarding the stereognostic sense, or power of recognising objects by handling them, Dr. Mackintosh said that in the case of the hand it was made up of the spacing sense or power of recognising two or more separate impressions as separate ones, the localisation sense and the muscle sense. The sense of weight, of pressure, of temperature, &c., had also some effect but, extraordinary as it might seem, touch was considered to be unnecessary. These various senses got correlated in the cortex, possibly in the superior parietal convolution. Dr. Mackintosh considered that the most important memory of an object was the visual, so that the visual centre was connected to the stereognostic centre. In a case of his own where the patient's stereognostic and visual powers were intact, while he failed to name any particular object, a tumour was found lying between the auditory and the visual centres, so that the stereognostic and the auditory centres must be connected *viâ* the occipital lobe and not directly one with the other.

May 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

A NEW scheme is to be put forward for remodelling the Irish Medical Association. It has been drawn up by the reorganisation committee and aims at doing away with centralisation and official rule. Every member is to have a vote and influence in the affairs of the association. The supreme authority of the association is to be invested in the general meetings, the council is to be the executive with such powers only as may be conferred on it by general meetings, either by articles of association or by resolutions passed from time to time. On only one point practically has there been a difference of opinion, that being in regard to the appointment of members of council. The majority recommended that each province should elect four members but that Dublin should elect four—making a total of 20. These 20 would then coöpt three more—making a total of 23. A certain number of members, however, were in favour of having a councillor elected by certain areas, making in all 14 councillors, with, in addition, a president, honorary secretary, and five general councillors elected by the whole association, making a total of 21.

Water-supply of Dublin.

Some months ago a warning appeared in the daily journals that a difficulty as to the water-supply of the city, such as occurred in 1893, might be anticipated. Later, however, it was stated that the Vartry reservoir had overflowed on three occasions and that the supply for the summer was ample. Now a circular notice from the corporation of Dublin has reached the citizens of Merrion-square and Fitzwilliam-square containing many annoying restrictions concerning the service of water for sanitary purposes. Among other regulations the document states that the flushing of water-closets must in future be restricted to a cistern containing only two gallons and not four as hitherto. If this order be enforced it will cause much annoyance and expense to the citizens, for they will be obliged to remove their cisterns of an average capacity of four gallons and replace them with smaller ones. Mr. Burton Phillipson, a member of the Royal Sanitary Institute of Great Britain, published a letter in the Dublin morning journals of May 29th in which he states that all sanitary experts know that a four-gallon flush gives far better results, not only in cleansing closet basins, but in washing the drains and sewers; in fact, he says, a four-gallon flush is by no means waste. The corporation has from time to time agreed to serve water to outlying additional districts and when Bills were before Parliament evidence was always given that the supply for such districts was ample. The citizens have paid a large sum for their water service which has been adequate and satisfactory for years. It seems intolerable in the circumstances that they should now be asked to undertake great compulsory expense and inconvenience, more especially as the canal which so effectively helped the Vartry mains in 1893 is still available.

The Infectious Diseases Hospital, Belfast.

The public health committee of Belfast has unanimously decided to recommend to the city council Dr. A. G. Robb as physician to the new infectious diseases hospital. Dr. Robb is physician to the union fever hospital and he had charge during the recent epidemic of the isolation hospital for small-pox. His selection will have the entire concurrence of the medical profession.

Hospital Saturday in Belfast.

About £700 have already been received at the Royal Victoria Hospital, Belfast, as the result of the effort on May 27th. The accounts are still far from complete and it is expected that this year's collection will be the largest on record.

Fever Epidemic in Newtownards.

Newtownards, a town of over 9000 inhabitants, situated on the northern extremity of Strangford Lough, eight miles from Belfast, is in a serious condition, as it was reported at a meeting of the board of guardians on May 27th that there were 47 patients at present in the fever hospital, 35 of whom were suffering from typhoid fever and 12 from scarlet fever. All the accommodation is used up and three cases of diphtheria had to be taken to the infirmary where they were isolated. To meet the great overcrowding some temporary rearrangements have been made in the hospital and if the epidemics increase and these arrangements are not sufficient hospital tents are to be procured and to be used as convalescent wards. The epidemic is due to defective water-supply and bad sewerage and the whole facts have been laid before the Local Government Board by its medical inspector. It is hoped that prompt action will be taken to remedy these serious defects.

Ulster Medical Society.

The eleventh general meeting of this society was held on May 25th in the Medical Institute, Belfast, when Professor W. St. Clair Symmers gave a demonstration of the lesions produced by the ova of bilharzia hæmatobia, illustrated by lantern slides and a large number of preparations. At the conclusion of the address a vote of thanks was passed to Professor Symmers on the proposition of Sir W. Whitla, seconded by Professor J. A. Lindsay.

The Vacant North Donegal Coronership.

In connexion with the election of coroner for North Donegal, an office rendered vacant by the recent sudden death of Mr. W. O'Doherty, M.P., there are already half a dozen candidates in the field—four solicitors and two medical men, Mr. Patrick O'Callaghan of Carndonagh and Mr. Neal Nelson of Buncrana. The appointment, which is to be made on June 12th, rests with the Donegal county council.

May 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Cough in the Tuberculous.

AT the meeting of the Therapeutical Society, held on May 10th, M. Berlioz drew attention to the use of narcyl in cases of tuberculosis. He was enabled to state that this drug soothed the cough and could be administered for a long time without causing any inconvenience. M. Berlioz had analysed his own urine as well as that of patients while taking the drug and had ascertained that narcyl had a good effect upon nutrition, for it raised the coefficient of oxidation. Neither the frequency of the pulse nor the blood pressure was increased. Patients taking narcyl felt no difference in their appetite, in their digestive powers, or in their intestinal functions.

Amputation of the Arm and Shoulder Girdle for Malignant Growths.

At the meeting of the Society of Surgery, held on May 10th, M. Berger read for M. Jambrau a paper on the above subject. The growth in M. Jambrau's patient was a large sarcoma. He recovered well from the operation but died from recurrence about a year later. M. Jambrau had collected 188 cases of similar amputations and stated that the mortality was about 11 per cent. M. Kirmisson said that he had only had one case, a child, aged ten years, in whom he had performed amputation for a large sarcoma of the upper end of the humerus. The child died from recurrence at the end of about six months. M. Schwartz had had better fortune. He had performed the operation for a chondroma eight years ago and up to the present the patient had had no recurrence.

Suture of the Liver for a Bullet Wound.

At the same meeting of the Society of Surgery M. Couteau gave an account of a case of a patient who had been shot by a revolver. On the inferior face of the right lobe of the liver was a wound corresponding to the wound of entrance of the bullet. On the posterior portion of the left lobe was another wound marking the wound of exit. M. Couteau sewed up both wounds with an overcast (*en surjet*) suture. The right kidney was also wounded. The patient, however, died and at the post-mortem examination M. Couteau found another wound which had been overlooked. This was on the inferior face of the left lobe of the liver and was the actual wound of entrance. The wound in the right lobe was merely a gutter ploughed by the bullet on its way.

A Short Way with "Sorciers."

In the month of February Madame —— wrote to the commissary of police stigmatising a certain "medical man" as a wizard (*sorcier*). Madame —— had accompanied a friend who wished to undergo treatment to this man's house. She got no better and completely loss her reason. Madame —— therefore asked that his establishment should be closed if possible. The case came before the tenth court of the Tribunal and the *sorcier* having no medical diploma was prosecuted for illegal practice of medicine. In cross examination he said that all he had done was to massage the patient over her clothes, and that he only treated people without pretending to cure them (*pratiquant seulement l'art de soigner et non de guérir*). After hearing other evidence the court condemned him to pay a fine of 500 francs and 1000 francs damages to the Syndicate of Medical Men of the Seine.

Late Suture of a Divided Ulnar Nerve.

At the meeting of the Society of Surgery, held on May 17th, M. Chaput showed a patient who 14 years previously had divided his ulnar nerve. A few months ago M. Chaput had operated by cutting down on the divided ends, refreshing them and uniting them by suture. The result was most satisfactory, sensibility returned, the interossei which were completely atrophied had recovered in great part, and although the patient could not completely extend his fingers, yet his hand was very fairly useful.

Electric Rectal Douches for Constipation.

Constipation, so frequent in women, is often connected with uterine troubles, especially uterine congestion, with or without displacement. Electrical treatment in such cases has a double advantage, for while according to the method of application it diminishes spasm or increases the contractile power of the gut, it also has a marked effect in reducing uterine congestion. The uterine treatment of constipation is useful in direct relation to the amount of uterine reflex causing the constipation. M. Burais of Vittel gave an account of such cases before the Medico-Chirurgical Society on May 8th. His conclusions were that electrical rectal douches are indicated in cases of acute constipation where an evacuation of the bowel is urgently required and in chronic cases in which the object is to restore the intestinal tone. Other means of treatment are not to be neglected, such as exercises, massage, and, above all, attention to diet.

Extraction of Foreign Bodies from the Respiratory Tract.

At the meeting of the Society of Surgery held on May 17th M. Sebileau read an account of two cases of foreign bodies in the bronchi. The first was that of a man, aged 63 years, on whom tracheotomy and inferior bronchoscopy were performed. These methods of procedure enabled M. Sebileau to extract two small bones. After the patient had undergone a series of pulmonary troubles, due to the sojourn of the foreign bodies, he made a perfect recovery. In the second case the foreign body was a pin some five or six centimetres long which had stuck at the second bifurcation of the bronchus on the right side. Tracheotomy was performed and two days later inferior bronchoscopy, after which M. Sebileau easily extracted the pin with Kilian's forceps.

May 30th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Schiller's Connexion with Medicine.

AT a meeting of the Clinical Society held on May 5th Professor Neuburger read a paper on the influence which his early medical training had on the poet Schiller. It was well known that his patron, Prince Karl [illegible]ust, originally intended that Schiller should be an [illegible] surgeon and his writings contained numerous indicati[illegible] the impressions made on him at this period. His phil[illegible]cal, metaphysical mind was already developed in his yo[illegible]nd when 21 years old he had written several very in[illegible]ng essays which might be termed "psychophysical." [illegible] of his writings about this time was the treatise on "T[illegible]onnexion between the Animal and Spiritual Nature of Ma[illegible] The leading idea of this little dissertation was that bod[illegible]d soul influence each other mutually and that sensual fe[illegible]ing brings forth mental actions; that the individual is dependent on his instincts to develop the mental faculties; and that nations require danger, hunger, and want to produce cultivation. Professor Neuburger went on to show how often Schiller applied his medical knowledge in his poetry and how well he had learnt to observe accurately not only the body but also the soul.

Occlusion of the Anterior Openings of the Nose.

At the monthly meeting of the Laryngological Society some interesting cases were shown by Dr. Menzel, assistant to Dr. Hajek. The first was a case of congenital membranous occlusion of both anterior nasal openings, this being an extremely rare condition. Several attempts had been made to establish a passage for the air through the nose, but all had failed. The interesting point was that the mucous [illegible] hus proving [illegible] sible for the [illegible] obstruction [illegible] monstration several speakers remarked that in cases of occlusion of the choanal openings there was also a normal pharynx which after operation showed the symptoms of chronic hypertrophic or atrophic pharyngitis. This had clearly been caused by the discharge from the nose coming into contact with the normal mucous wall. Dr. Roth said that such occlusions as the one shown were most likely due to syphilis because the really congenital occlusions were situated quite at the introitus nasi, whilst the present one was further back at the level of the anterior end of the lower turbinated bone. Another of the cases was one in which the frontal sinus was so developed on the right side that it compressed the left sinus and filled its place. The left sinus was only as large as a pea but could be identified as a sinus by having its own opening into the left nostril.

An Antivivisection Speech by a Government Official.

At the opening of a new hospital at Linz some days ago a high official made an attack on the carrying on of experimental research for the advancement of medical knowledge. When eulogising the benevolent donors by whose aid the institution had been erected, he astonished the medical men, town councillors, and [illegible] that none of the mod[illegible] would be permitted in [illegible] utility of such experim[illegible] obtained. Dr. Brenner, who was the next speaker, did not conceal his surprise at such unreasonable remarks on the part of a man supposed to be well acquainted with the results and objects of modern research. The hospital, he said, would be a home for the sick and a help for the weak, and he also hoped that in it some of the mysteries of human life would be investigated and perhaps solved.

Adrenalin in Asphyxia.

At the last meeting of the Gesellschaft der Aerzte Dr. Joseph Winter read a paper on experiments which he had made on the action of extracts of the suprarenal gland on the mammalian heart when under the influence of an overdose of chloroform. He had found that, as Lowton and Sherrington had shown, the heart of a cat stopped beating when transfused by a solution of chloroform of strength 1½ per 1000. Dr. Winter isolated a cat's heart and sent through the aortic valve and the coronary arteries the above-mentioned solution. After five minutes a solution of sodium chloride made to transverse the same route caused no contractions, but when 15 minutes were allowed to elapse and a solution of adrenalin of strength 1 in 2000 was injected the heart began to beat again. These experiments were conducted in several ways and always with the same result. Cats and rabbits were then submerged in water for ten minutes and artificial respiration being of no use he again injected a solution of adenalin chloride into the heart which now resumed its beating. It is to be hoped that the method will be improved so as to be capable of application to the human subject. Dr. Winter thinks that it will be useful not only in cases of drowning and asphyxia due to cardiac poisons such as alcohol, chloral, and chloroform but also in combating surgical shock.

May 29th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Bengal Jails.

THE resolution of the Government on the annual report of the jails of Bengal has just been published. It shows that many o[illegible] and in[illegible] daily r[illegible] the yea[illegible] feature [illegible] daily a[illegible] the last [illegible] mortality and during the last three years the rates have been 25·6, 23·6, and 20·2 respectively. The mortality from malarial fever has largely declined. In spite of the prevalence of plague only one jail was attacked. This was at Chapra, where the jail is situated in the heart of the town. A number of important changes have been introduced in diet. An allowance of a [illegible] the staple food of [illegible] increase of oil and [illegible] have [illegible] jails anc[illegible] is that peo[illegible] being the [illegible] system in o[illegible] ss and requi[illegible] involves much clerical labour and the separate cell system involves more accommodation than is available. Corporal punishment is employed generally as a last resort.

The Parsee Maternity Hospital in Bombay.

The annual report of the Parsee Maternity Hospital in Bombay shows a continued record of really good work. Its popularity amongst this community is remarkable because out of a total of 1304 births among the Parsees no less than 535 occurred in this hospital. The hospital is always full and many have to be refused admission. The example set by this hospital has been followed by the Khojas and Bhattias and Bunyas who have now established separate hospitals for their respective communities. In the Parsee institution a certain proportion of the poor are admitted but the majority pay. Infant mortality in the hospital seems to be much lower than in the homes of the people, as only ten deaths occurred amongst the children born in the hospital while 59 occurred amongst those outside.

The Plague Mortality throughout India.

The plague mortality throughout India has again shown a rise; for the week ending April 29th there were returned 56,732 deaths, as against 54,602 for the previous seven days. The principal figures are: Punjab 28,728 deaths, as against 27,372 last week; United Provinces 15,710, as against 16,737; Bengal 4108, as against 3559; Rajputana 4298, as against 2406; Bombay Districts 1443, as against 1766; Burmah 137, as against 175; Kashmir 368, as against 215; Bombay city 935, as against 1021; and Calcutta 624, as against 792. The first attack in Rangoon has been severe, though the outbreak is declining. Up to April 30th 1053 cases with 937 deaths had been recorded. A satisfactory change seems to be taking place in public opinion with regard to inoculation. In Karachi the managing committee of the corporation has recommended that to popularise this prophylactic amongst the subordinate staff, especially among the sweeper class, an inducement of one month's salary should be given to those who come forward with their families to be inoculated. In Bombay a citizens' meeting was held with the object also of popularising this measure and an influential committee was appointed. As every precaution is now being taken in the manufacture of the prophylactic and it is stated that Dr. Martin was satisfied with the methods of preparing it, and, further, as its influence for good continues with each year to be capable of proof, we are now looking forward to a Government recommendation of it.

May 12th.

Obituary.

EUSTACE TALBOT, M.B., B.C. CANTAB., M.R.C.P. LOND.

THE death is announced from appendicitis on May 26th of Dr. Eustace Talbot. Some years previously he had suffered from a mild attack of the same complaint, but in the interval had not been troubled with any signs of a recrudescence. He was in his usual health and at work as late as the afternoon of May 18th but in the evening began to complain of symptoms which pointed to a fresh attack of the former trouble. His condition became rapidly worse and an operation was performed on May 21st. During the next four days, though his condition was still dangerous, he appeared to be doing well, but on the afternoon of the 25th he had a severe attack of abdominal pain and died a few hours later.

Eustace Talbot was the youngest son of the Right Hon. J. G. Talbot, M.P. He was educated at Winchester and Trinity College, Cambridge. It is not necessary here to make more than a brief reference to his years at the University. He threw himself with eagerness into all the many spheres of active life and in each his enthusiasm, his gay humour, and his personal charm insured him success and esteem. He attained the distinction of a "blue" for tennis; he edited the *Granta* for a year, had a large share in the management of the A.D.C., and was on the committee of the Pitt Club. But, as he often said, the best result of his years at Cambridge was the acquisition of the numerous friendships which were the delight of his life and again and again drew him to revisit Cambridge. He went to St. Bartholomew's Hospital in 1896 and found there many friends who had preceded him and others to whom he was already well known. As at the University, he entered into all the life of the medical student and at the same time quickly acquired a knowledge of his profession which was remarkable in one who was so ready to acknowledge the claims of society outside the hospital. He qualified in 1899 and almost immediately became house physician, and subsequently resident medical officer, at the Royal Hospital for Diseases of the Chest, an appointment which he relinquished to become house physician to Sir William Church at St. Bartholomew's Hospital. This appointment was cut short by an attack of hæmoptysis which led him to spend a considerable time at Davos. He revisited Davos every winter, although his health was fully re-established, and there, as everywhere else, made numerous friends. In 1901 he became a Member of the Royal College of Physicians of London and seized every opportunity of clinical experience which came in his way. He worked at Queen-square, at the Children's Hospitals at Great Ormond-street and Shadwell, and at the City-road Hospital for Diseases of the Chest. In 1904 he was appointed casualty physician at St. Bartholomew's Hospital and assistant physician at the City-road hospital. He was also physician to the Sun Life Assurance Office. Thus, although handicapped by the failure of his health at an early period of his medical career, he had secured a position which made ultimate success certain, and a further appointment in the medical school as assistant curator of the museum gave him additional assurance of attaining the object of his ambition, a place on the medical staff of St. Bartholomew's Hospital. But the grief felt by those who knew him, for the untimely end of a career of such promise is less than that for the loss of a friend. There was no sphere in the life at St. Bartholomew's in which he did not take a full part. He undertook the editing of the hospital journal at a time when it was at a very low ebb and gave it a new life; he was an enthusiastic member, and afterwards President, of the Abernethian Society, and though not a first-class cricketer was an invaluable member of the hospital eleven, and later one of its constant opponents in the Past *v.* Present matches.

To those who did not know him it is impossible to give in words any idea of Eustace Talbot's personal charm and for those who did know him it is superfluous to attempt it. The fascination of his personality was due principally to his absolute sincerity and honesty, combined with a lively humour and a temper which nothing could disturb; to these were added a [illegible] experience of the various circles of society, in all [illegible] he was a welcome guest, and a ready appreciation [illegible] ood points of those with whom he was thrown. At [illegible] olomew's the blank he has left will be filled only w[illegible] memories:

> "No weakness, no contempt,
> D[illegible] ame, nothing but well and fair,
> A[illegible] quiet us."

The funeral [illegible] took place on May 30th, was attended by numerous f[illegible] from different parts of the country; and a memorial ser[illegible] held at the same hour at St. Bartholomew-the Less was attended by many of the medical staff, the sisters and nurses, and students of St. Bartholomew's Hospital.

GEORGE LONGBOTHAM, M.R.C.S. ENG., L.S.A. LOND.

IN the death of Mr. George Longbotham, who passed away at Harrogate on May 10th, the profession has lost a member whose example can ill be spared and of whom it may be said that his ethical actions formed the chief glory of his life and will remain his greatest claim to remembrance. Born at Chester-le-Street, in the county of Durham, in 1845 he was educated at the Newcastle School of Medicine and took the diplomas of L.S.A. and M.R.C.S. Eng. in 1866 and 1867 respectively. He then joined his uncle in practice at Seaton Carew, county of Durham, but after a time removed to Leeds, and subsequently to Middlesbrough, where he practised for 26 years. He left Middlesbrough five years ago, first for Ilkley and then for Harrogate, where soon afterwards unmistakeable signs of declining health became evident. In addition to being medical officer to the union infirmary in Middlesbrough he was on the staff of the North Riding Infirmary in the same town for many years. He was also a Past Master of the Ferrum Lodge of Freemasons. The funeral took place at the Middlesbrough cemetery on May 13th. Mr. Longbotham has left a widow, one daughter, and eight sons, the eldest of whom is a medical practitioner in Middlesbrough.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Michael Cherinoff, professor of medical diagnosis in the University of Moscow.—Dr. Friedrich, surgeon-general in the Bavarian army.—Dr. Eduard von Fichte, surgeon-general in the Würtemberg army and nephew of the philosophical writer, Johann Gottlieb Fichte. He was 79 years of age.—Dr. Savarikin, formerly professor of histology in the Military Medical Academy, St. Petersburg.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Keepers of licensed lodging-houses, in which students are residing, are to be required to notify to the Syndicate the presence in their houses of "any infectious disorder, including consumption or any other form of tubercular disease."—Dr. Donald MacAlister has been appointed by the Senate a member of the Syndicate for Instruction in Forestry; he has also been appointed deputy for the Vice-Chancellor as chairman of the Board of Geographical Studies.—Mr. J. J. Lister, F.R.S., St. John's, has been appointed to occupy the University table at the Plymouth Marine Biological Laboratory.—The Medical School Buildings Syndicate reports that [illegible] on the new buildings and [illegible] will still be required for the [illegible] he source of supply, unless the much-desired benefactor comes forward, is not apparent.—Honorary degrees are to be conferred on His Excellency the French Ambassador (M. Cambon), Sir Edmund Monson, Sir Robert Finlay, Professor Vinogradoff, Lord Reay, Father Denifle, Professor Driver, Father Ehrle, Professor Gildersleeve, Mr. Frederic Harrison, Commander R. F. Scott, and Sir Francis Younghusband.—The following degrees were conferred on May 25th:—

[illegible] C. H. A. Kellie, Caius; W. V. [illegible] ash, Emmanuel, and J. H. F. [illegible]

[illegible] ow, Trinity; J. R. C. Greenlees, [illegible] Peterhouse; W. V. Braddon, *Trinity Hall*; *N. C. Fletcher, Queen's*; and *W. C. P. Ellis*, St. Catharine's.

UNIVERSITY OF LONDON.—At examinations held in May the following candidates satisfied the exminers:—

M.B., B.S. EXAMINATION.

H [illegible] ward C. Norbury, [illegible] ns, University of [illegible] Lancey Robinson, Guy's Hospital; William Mackenzie Sailer, University College; John Noel Sergeant, St. Thomas's Hospital; Ida Russell Shields, London (Royal Free Hospital) School of Medicine for Women; William Herbert Smailes, University of Leeds; Sarah Charlotte E. Sommer, Alice Maude Sorabji, and Mary Marguerite L. Taylor, London (Royal Free Hospital) School of Medicine for Women; Gordon Wilson Thomas, University of Leeds; Ethel Maude Townend, London (Royal Free Hospital) School of Medicine for Women; Edwin Robert Wheeler, King's College; and Frank Thomas H. Wood, B.Sc., Guy's Hospital.

The following candidates have passed in one of the two groups of subjects:—

Group I.—Arthur [illegible] pool; Frederic I [illegible] aring Cross [illegible] Alexander [illegible] pital; and [illegible] University College.

Group II.—Valentine Henry Blake, St. George's Hospital; George Archibald Bosson, University College; Alwyn Hewett Bradley, University of Birmingham; George Percival Charles Claridge, St. Mary's Hospital, Isaac Reginald Cook, Guy's Hospital; Frank Bell Dalgliesh, St. Thomas's Hospital; George De la Cour, University College, Jeannette Rachel De Pass, London (Royal Free Hospital) School of Medicine for Women; Albert Davies Edwards, London Hospital; Douglas Edward Finlay and Hyman Isaacs, St. Mary's Hospital; George Francis Jones, University College; Ste [illegible] Hospital; Robert *Leslie Ridg* [illegible] *London Hospital*; Charles Cha [illegible] hhead Scott, University Colle [illegible] Sc., London (Royal Free Hospita [illegible]

B.S. EXAMINATION.

[illegible]), King's College [illegible] rin, London and [illegible] Guy's Hospital; [illegible]; Ruth Balmer, [illegible] or Women; Frank [illegible] Félix, [illegible] spital; [illegible] illiam [illegible] Mid- [illegible] omas's [illegible] illiam [illegible] acker, [illegible] omen; [illegible] a Uni- [illegible] ospital; and Samuel [illegible] candidates, is issued subject [illegible]

ROYAL BRITISH NURSES' ASSOCIATION.—In the gardens of the Royal Botanic Society, Regent's Park, N.W., on June 7th, at 3 P.M., a garden party and conversazione will be held in connexion with the Royal British Nurses' Association. The annual meeting will take place in the museum of the gardens on the same date at 4 P.M. The address of the secretary is 10, Orchard-street, Portman-square, W.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this society was held on May 22nd, Mr. Christopher Heath, the President, being in the chair.—The report for 1904 was adopted and was as follows. During the year nine new members were elected, five members died, and five resigned. At the end of the year there were 149 life members and 144 subscribers. Two widows were elected and three widows died, there being 52 in receipt of pensions at the end of the year. Two orphans were elected and one became ineligible, leaving 16 in receipt of pensions. The directors have to record, with great regret, the death of Mr. Joseph B. Blackett, who had for 37 years ably filled the office of secretary to the fund and they have appointed Mr. Edward Blackett to fill the vacancy until the July quarterly court of directors, at which the secretary is annually elected. During the year the sum of £3214 10*s.* had been distributed amongst the annuitants of the charity. The invested capital of the society now amounts to £98,810. The advantages of the society cannot be *too strongly* urged upon the members of the medical profession, especially the younger ones, for it is open to all registered medical practitioners who at the time of their election are in practice within a radius of 20 miles from Charing Cross. The annual subscription is £2 2*s.*, payable either in one sum, or in two half-yearly ones of £1 1*s.* After election members are at liberty to live outside the 20-mile radius, nor is their residence confined to the British Isles, there being members now on the books resident in Canada, South Africa, Rome, and Egypt. Relief is only granted to the widow or orphans of a practitioner who had at the time of his death been a member of the society for three years [illegible] can realise the number of applications that are being constantly received from widows of medical men left totally unprovided for and relief has in the vast majority of cases to be refused owing to the fact that the late husband had not been a member of the society. The amount of the grant given is regulated by the two following by-laws:—

> The widow of a member who has no certain income or provision exceeding altogether the yearly value of £80 is eligible to receive, half-yearly in advance, such relief from the society as the court of directors shall determine, and in determining the amount of such relief regard shall always be had to the age of the applicant, her ability to maintain herself wholly or partially, and to the amount of subscriptions her deceased husband shall have paid. Whenever the death of the member has been caused by a sudden accident or illness in the pursuit of his professional duties the court of directors may decide to make an *additional grant in favour of his widow not exceeding £25.*
>
> The widow of a member who is left with a child or children under 16 years of age entirely or in part dependent on her, and whose certain income or provision does not exceed altogether the yearly value of £15 for each child, in addition to the £80 mentioned in By-law LXIX., is eligible to receive such additional assistance, half-yearly in respect to each child under 16 years of age, as the court of directors shall determine, but if such child or children have any provision independent of the mother such provision must be distinctly stated to the directors in the *usual half-yearly declaration of the widow.*

Further particulars of the society can be obtained by sending a stamped envelope to the secretary at 11, Chandos street, Cavendish-square, W.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held on May 25th, at 6, Suffolk-street, Pall Mall, London, Dr. F. H. Champneys being in the chair. The Board heard the following charges alleged against Annie Bord, a certified midwife: 1. That being in attendance on the confinement of a certain woman she was guilty of disobeying the rules of the Board in the following respects: (*a*) on the occurrence of rigor she did not decline to attend alone nor did she advise that a registered medical practitioner should be sent for as required by Rule E 17 (c) (I.) (4); (*b*) on the occurrence of foul-smelling discharges, lasting during several days, she did not decline to attend alone nor did she advise that a registered medical practitioner should be sent for, as required by Rule E 17 (c) (I.) (2). 2. That having been in attendance on a patient suffering from puerperal fever she did not disinfect herself, or her instruments, or her other appliances, or her clothing to the satisfaction of the local sanitary authority before going to another labour. Annie Bord attended the meeting and protested her innocence, stating that even if she had done anything wrong it was in consequence of her ignorance of the rules of the Board. The decision of the Board was that the name of Annie Bord should be removed from the roll of midwives and the chairman stated that he hoped that the decision of the Board would be a warning to midwives that they cannot plead ignorance of the rules of the Board. Midwives must remember that they must not speculate in the lives of their patients but must bear in mind the responsibilities of the sacred trust committed to their charge. The Board next heard the following charges alleged against Georgina Eliza Price, a certified midwife. (1) That being in attendance on the confinements of certain persons she was guilty of malpractice, negligence, or misconduct while in the performance of her duty as a midwife; (2) being drunk when in attendance on certain cases. This midwife was represented at the meeting of the Board by Mr. P. R. Simner, who was instructed by Mr. H. D. Brown. The Board decided in this case that the midwife Price should be severely censured which was accordingly done by the chairman. The Board then considered the following charges alleged against Martha Maria Herbert, a certified midwife: 1. That being in attendance on a woman in labour she was guilty of disobeying the following rules of the Board: (*a*) the case being one of breech presentation in a primipara she did not decline to attend alone nor did she advise that a registered medical practitioner should be sent for, as required by Rule E 17 (a) (1); (*b*) she did not express the placenta, as directed by Rule E 17 (b) (4), but within 20 minutes of the birth she pulled on the cord and then inserted her hand into the vagina and detached the placenta. 2. That having sent for a registered medical practitioner on the occurrence of secondary post-partum hæmorrhage she failed to notify the same to the local supervising authority, as required by Rules E 17 and 19 (b). 3. That she undertook the duty of laying out the dead, contrary to Rule E 15. The midwife Herbert did not attend and the Board decided in this case that she was to be censured. Accordingly direc[illegible] of the Board to that effect.

UNIVERSITY OF OXFORD: [illegible] DEGREE OF M.CH.—The [illegible] Master in Surgery will com[illegible] Department, University M[illegible] The names of candidates [illegible] the Board of Faculties, [illegible] June 9th. Particulars [illegible] the secretary of the Boards of [illegible] Clarendon Buildings, Broad-street, Oxford.

THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.—Viscount Clifden, presiding at the annual meeting of the friends of this hospital on Friday, May 26th, dwelt upon the great advantages of the institution, pointing out that everything was arranged most suitably and in accordance with modern ideas. He alluded to the large increase of legacies, lamented the small amount from annual subscriptions, and thought that the freedom of the institution from debt was worthy of imitation by other institutions, many of which thought that indebtedness was the most effective way of getting contributions. The Rev. Canon Barker, in seconding the adoption of the annual report, referred to the length of residence of patients, averaging 75 days, as showing the intent of the hospital to do good in all cases where possible, and regretted the unfortunate decision of the House of Lords in bygone days which still condemned the London hospitals to pay over £20,000 a year in rates.

FESTIVAL DINNER OF THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—Dr. E. C. Beale in replying to the toast of "The Medical Staff" at the festival dinner of the City of London Hospital for Diseases of the Chest, held on May 26th at the Trocadéro Restaurant, London, utilised the occasion by pointing out that the hospital could be made to yield greater benefits to the working classes if the local authorities would provide a suitable place for chronic cases which were past all hope of cure. He showed that by adopting modern methods of treatment the medical men at the hospital were able more and more to restore patients to their work and health and he had a word of praise for the hospital committee for the generous manner in which the demands of the medical staff were always met. During the evening subscriptions were announced to the amount of £2386. Among the amounts making up this total there were some heavy contributions from the working men's societies in the neighbourhood of the hospital.

GLASGOW UNIVERSITY CLUB, LONDON.—Sir William Ramsay presided on May 26th at the dinner of the above club which was held at the Trocadéro Restaurant, Piccadilly-circus, London. Immediately preceding the dinner the annual general meeting of the club was held and the report of the council for the year was of a very satisfactory description, 32 new members having joined, making the total membership 301. Lord Kelvin was re-elected president of the club and Mr. J. Dodds and Dr. C. O Hawthorne were elected honorary secretaries. Amongst those present at the dinner were Professor A. Ewing, Director-General A. H. Keogh, Lieutenant-Colonel W. Babtie, V.C., Brigadier-General Sir Ronald Macdonald, Sir G. H. Philipson, Professor J. Y. Mackay, Professor McCall Anderson, and Sir W. Thomson. The loyal toasts having been duly honoured the toast of "The Imperial Forces" was given by Mr. A. Ure, M.P., and this was replied to by Brigadier-General Sir Ronald Macdonald. Sir William Ramsay then submitted the toast of "The University and the Club" and interspersed his remarks with stories of the University of Glasgow. Professor Mackay, in proposing the toast of "The Guests", related with pride how the University of Glasgow had held aloft the lamp of learning in Scotland for many hundred years and was at the present time full of vigour and honour and dignity. This toast was acknowledged by Professor Ewing who, referring to Sir William Ramsay, said that he had once described him as an Argonaut, for he had brought back argon from a voyage into science, but Sir William Ramsay had lately looked into the sea-water and discovered a new *element*; in fact, the lexicons would be soon exhausted in finding names for the new elements which their chairman was discovering. Professor McCall Anderson then gave the toast of "The Chairman" which called forth from Sir William Ramsay another speech, with more Scotch stories, which ended the evening.

cussed the chances of the passing of the Nurses Registration Bill which he had introduced into the House of Commons on Feb. 23rd, 1904. He did not consider it possible for the Bill to be passed this session and in relation to its becoming law he used the somewhat vague term that the promoters of the Bill might be successful in the near future in getting the measure made law. The Bill had been down for a second reading on several occasions but had not been reached, as no place was secured in the ballot for its discussion; moreover, as it had been blocked it could not be discussed as non-contentious business after 12 o'clock. A great number of nurses were present at the meeting and Mr. Ferguson's explanation of the difficulties attending the passage of a private Bill through Parliament was very carefully listened to. The annual report stated that during the last year 300 applications for membership of the society had been accepted from matrons and certificated nurses, [illegible] the formation of the society [illegible] the report the work of the s[illegible]gely by voluntary labour and by this means and by the personal influence of many of the members interest in State registration of nurses had been aroused all over the United Kingdom and it was hoped that after due consideration of the question a consensus of opinion in its favour might ultimately be produced.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Experiments upon Live Animals.

THE Parliamentary papers laid upon the table of the House of Commons during the week have included a report prepared by the Home Office in regard to the experiments performed on live animals during 1904. It is explained that there was a large increase, which was accounted for mainly because of the progressive importance attached to biological tests generally in practical medicine for the diagnosis, treatment, and prevention of disease and by the more widely recognised need *for such experiments by those responsible for the care* of the public health. The Royal Commission on Tuberculosis made 1821 experiments in the course of the year; 5852 experiments were carried out for testing antitoxic sera and vaccines; and 8292 experiments, mostly [illegible]

[illegible] cautions fail and suppuration occurs the animal is required to be killed. Experiments involving the removal of important organs and even parts of the brain are performed without causing pain, and after the section of part of the nervous system the resulting degenerative changes are painless. In no case has a cutting operation more severe than a superficial venesection been allowed to be performed without anæsthetics and in no instance has a certificate dispensing with the use of anæsthetics been allowed for an experiment involving a serious operation. Unless a special certificate be obtained the animal must be kept under an anæsthetic during the whole of an experiment. In the event of pain ensuing as the result of an inoculation the animal has to be killed under anæsthetics as soon as the main result of the experiment has been attained. It is expected that on an early day this information will be made use of in debate in the House.

SELECT COMMITTEE ON REGISTRATION OF NURSES.

The Select Committee of the House of Commons, presided over by Mr. TENNANT, which is inquiring into the question of the registration of nurses met again on May 25th.

Dr. E. H. GREVES, general practitioner of Bournemouth, said he had had 20 years' experience in that resort and five in hospital at Liverpool. The result of that experience convinced him of the necessity of the State registration of nurses so as to have some guarantee that nurses had had some training. It would improve the status of nurses. With regard to the sick poor, his opinion was that district nurses having charge of that kind of case necessarily had a good deal of responsibility upon them because they were not so closely supervised, and it was therefore necessary that they should be efficiently trained. There might be a central committee or council for registration purposes and to direct the form of examination. He did not think it was possible for nurses to be trained efficiently in all work in less than three years. Witness mentioned that at a largely attended public meeting in Bournemouth last winter at which he presided a resolution in favour of registration of nurses was carried unanimously.

Replying to Dr. C. F. HUTCHINSON, witness said registration ought to be compulsory. If he were a country medical man he would emphatically welcome the highly trained nurse.

A little later witness said he would not prohibit nurses not registered by the State from practising but it should be made perfectly clear to the public that they were not registered.

Dr. HUTCHINSON asked how he could make that view agree with his opinion that registration should be compulsory.

Witness: I would not make non-registration penal.

Dr. HUTCHINSON: Then you make it voluntary. You are on the horns of a dilemma.

Witness said he should certainly vote for compulsory registration even if it necessarily followed that it would be penal to act as a nurse without being registered rather than let the present system continue. Witness believed registration would not retard the supply of nurses and that the same charitable sources which found nurses now would continue to do so.

Sir HENRY BURDETT was next called. He said although he was not engaged directly in the training or control of nurses he had a good deal to do with matters appertaining to nurses and was also consulted by people managing hospitals and institutions. The number of nurses had an important bearing upon the deliberations of the committee. Under the term of sick nurses and invalid attendants, according to the last census, there were 74,844 persons in the United Kingdom. From that number had to be deducted 9000 who were too young or too old or were evidently not nurses, reducing the number to 66,000 in round numbers. After most careful consideration he had come to the conclusion that two-thirds of the 66,000 could not be regarded for the purposes of this inquiry as trained nurses at all and if he were right the number of trained nurses the committee would have to consider was from 22,000 to 25,000. Witness made a number of calculations from which he arrived at an estimate of the certificated and trained nurses working in this country, the number not exceeding 30,000, even if, he said, it exceeded 25,000.

Regarding the supply of nurses witness said the main cause of the present evils was largely due to the profits which could be made by private venture homes and which made pseudo-nurses possible. The greater the demand for nurses the more variegated was the supply from these homes. It was a great temptation to anyone conducting this business and who found how profitable it was in times of epidemic or great pressure to send out to private families without much inquiry women who said they had been nurses. Speaking of the large percentage sometimes deducted from nurses for cooperation he said he knew from experience how enormous must be the profits of private venture homes in this respect.

Witness, in the course of some remarks on nurses' training in hospital, said the real training in the first year came mainly from observation and in his view the technical part of a nurse's work to equip her for this observation and period of extended instruction could be thoroughly done in 12 months. The linen and house-work could be largely curtailed. He hoped one result of this inquiry would be to secure reforms to promote the early coöperation of all engaged in the training of nurses so as to secure adequate technical training. The lack of coöperation which had hitherto marked the conduct of these institutions was not advantageous to the hospital nurse, the profession, or the public. Still there was a great deal of credit due to hospitals and nurses' training institutions which had brought modern nursing in this country to a high state of efficiency.

Passing to State registration, he maintained that the objects in view could be attained by better, simpler, and less expensive means than had been proposed in Parliament. It had been said that 60,000 nurses would register at once, either as trained nurses or as women who could satisfy the Board that they were in *bonâ-fide* practice before the Act passed. The consequences which would follow the letting loose on the public of 30,000 women not trained but recognised as registered nurses would make the bravest pause. Such must be one of the consequences of a time limit and if the lines of existing legislation were to be followed such a limit must be allowed. His suggestions were that Parliament should enact that all training schools for nurses and all hospitals and institutions that trained nurses, according to a given standard, should be registered and inspected, but the registration of such establishments should be made conditional on the training of nurses being carried out in such a way as to fulfil the standard laid down, and upon examinations being held on some such system as that which governed the proceedings of the General Medical Council; on the granting of certificates in a certain form; on the publication of a register each year of all nurses trained and certified by each such school and hospital; on the post-graduate training of all certified nurses who desired those facilities by the school where they were trained; providing further tha each training school and each hospital which trained nurses should afford its nurse graduates the opportunity, if they wished, of joining the private nursing staff attached to the institution and of having secured to them in liberal measure the payments received for their work. In this way, said witness, they would cut at the root of existing evils and in a few years those evils would be probably entirely removed. In any system including the proposals he had submitted it was essential that some provision should be made for those nurses who had not had the advantages of a three years' training in a single hospital but might possess excellent technical and moral qualifications for nursing. He thought Lord Rothschild's scheme for the higher education and training of nurses might usefully undertake the work for organising examinations for the benefit of this flowing army of irregulars. Those who passed the test should be granted the certificate entitling them to rank as qualified nurses.

Replying to the CHAIRMAN, witness said he would have the Registration Board or Council based on the lines of the General Medical Council.

The committee then adjourned.

Further evidence was taken on Tuesday, May 30th.

Mr. JAMES RUSSELL MOTION, inspector of poor and clerk of the parish council of Glasgow, stated, in reply to the CHAIRMAN, that the council passed a resolution in favour of registration. It was strongly felt that something should be done for the protection of the public, the nurses, and the medical men. At the present moment the Poor-law nurses in Glasgow were registered under the authority of the Local Government Board of Scotland. This was done under a Treasury minute in connexion with the grant of £20,000 for medical relief. The Secretary for Scotland determined that that sum should be distributed among the parochial boards of Scotland which had applied it under rules and conditions in payment of a portion of the cost of trained sick nursing in poor houses and so on. Under that grant the local authority had been able to register the nurses it employed who had trained for two years and had passed an examination. The local authority declined to accept the services of any nurse who should not be able to pass the examination, because by doing so it would lose the half of her salary and maintenance which the grant afforded. A trained sick nurse must not have less than two years in a public hospital or a training school for nurses which maintained a resident medical or surgical officer; she must not be under 22 years of age or over 45; and no grant was made in respect of nurses who had not entered in the register. It was in the power of the Local Government Board to remove the name of any nurse from the register. He found that there was a sufficient supply of nurses for the hospitals and institutions of the parish council. As the Local Government Board could do this work of registration he would ask why it could not be done for the whole country. In their own hospitals the council found that two years' training was sufficient. The council had 227 nurses, of whom 144 were probationers.

By Sir JOHN BATTY TUKE: There should be some universal examination, because one medical officer might be strict and another lenient.

By Mr. MOUNT: Those nurses who stayed over the two years in the council's hospitals were registered.

By Mr. KENNETH BALFOUR: The medical officers of Glasgow had not, to his knowledge, passed any resolution on this subject and he had no knowledge of any meeting of medical [illegible]

By Mr C. HOBHOUSE: The system of [illegible] was practically dependent on the grant of the Local Government Board, but he did not think that in the event of that grant being withdrawn the system would disappear. He, for one, would do his best to keep registration at its present standard. The council's system was to have two years' compulsory training and one year's voluntary training, but he would like to see another year added.

Then your view of registration is that you would like to prevent the supply to the public of nurses who have less than three years' training?—Yes. Continuing, he said that there was no scarcity of nursing and ladies [illegible] the hospitals to train. The great bulk of the n[illegible] three years.

By Mr. DOUGLA[illegible]rish council was to have a hall-mark for nurs[illegible]ad no interest in restricting the supply. He was not clear that the object could be gained by voluntary registration but if it could be achieved he would say by all means let them have it.

By Mr. PIERPOINT: The great bulk of the nursing in working men's families was carried on by nurses attached to churches or other bodies. There were people who looked after their neighbours when they were ill but who did not get payment.

Sir JOHN BATTY TUKE: But you must have a certain number of so-called nurses who are not fully qualified and who are practising for gain?—I have no doubt there will be some such nurses. A self-respecting nursing institution would not send out a nurse with only one year's training. It is very much to be desired that that practice should cease.

If you stop these women nursing who are to take their places?—I do not admit that that is nursing.

But registration would interfere with those women of one year's or no training?—Certainly. It will interfere with those women who are masquerading as nurses, but it will not affect the general supply of nursing.

Miss SHANDON, matron of the Western Infirmary of Glasgow, stated that she was in favour of registration. At that infirmary they had a system of examination twice a year and from 15 to 18 went up. The percentage of passes was very high. The examination was difficult and she attributed the almost universal success of the candidates to the fact that they were very capable and competent women and to the good training they received. There had been no expression of opinion on the part of the nurses in Glasgow in regard to registration. The question had not been taken up very much by them. She did not favour the institution of two classes of nurses. It would not work because the untrained nurse would occupy the position she now occupied and the public would not be protected. She saw no difficulty in the way of getting a sufficient number of nurses. If thoroughness of training and good character could be secured by voluntary State registration she agreed that that would be a good scheme. She would steer clear of punishment if that were possible.

By Sir J. STIRLING-MAXWELL: The nurses at the Western Infirmary were not drawn from the domestic servant class. They were generally the daughters of professional men and farmers. Very few came from the so called gentle class. She thought a fee of five guineas would not stand in the way of registration.

[illegible] Nurses who had been trained during only [illegible] good work, but she did not know that it was [illegible] trained nurse's point of view she thought it was worth nothing at all. She admitted those nurses did some good but not much.

Mr. GEORGE WILLIAM DUNCAN, secretary of the Central Midwives Board, said that the system of examinations under the Board was only beginning and the first examination would be held next month. For that the fee would be one guinea, but it would not be sufficient to pay for the examination. He would suggest the raising of the fees. It was too soon to say anything as to the permanent working of the Midwives Act. The normal

Notes, Short Comments, and Answers to Correspondents.

"EMPIRICAL SCIENCE."

WE have received a document from a gentleman, named H. C. Hiller, dated from Didsbury, Manchester, numbered "Pamphlet 8," and informing us that a book of his can be obtained at a certain price from a certain publisher, while inclosing a preface to the work. The author apparently is a critic of science, or, as he prefers to call it, "empirical science," and perhaps the previous pamphlets have made his position clearer. At any rate, we should not guess, from the evidence with which he supplies us, that he is a very wise person. All the same, he has thought of an original method of advertising his work, and if only the representatives of "empirical science" would have been kind enough to fall in with his suggestion he might have done good business. He appears to have written to Lord Rayleigh, Lord Kelvin, Sir Oliver Lodge, Sir James Dewar, Sir William Crookes, Professor William Osler, Professor A. Schuster, and Professor Horace Lamb, inviting them to read advance sheets of his book, and "if you consider my position vulnerable in important respects expose the defects, your exposure to be embodied or not at your option in the book." Now it is an undoubted fact that whereas the public might not be particularly anxious to hear of "the new science of causation" (the subject of the book) from the pen of Mr. Hiller, they would like very much to hear anything from the pens of Lord Rayleigh and the other distinguished physicists. A good many authors of standing would have no objection to receive beforehand expert criticism of their work so that they could purge their work from obvious faults, or alter its tenour in inconvenient places, but it has been left to Mr. Hiller, we think, to devise a scheme by which the publication of criticisms—presumably adverse—of his work should float his publication. Lord Rayleigh and the others may be exponents of "empirical science," whatever that is, but they knew too much to fall into Mr. Hiller's little trap. They have all decided not to read Mr. Hiller's advance sheets and we have decided not to read his book.

AN OLD LANCET CASE.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "Provenance," who asks for particulars *re* an old lancet case, I should say it was somewhat doubtful whether the lancets *mentioned* are *contemporary* with the case. "Savigny & Co." was a very noted firm of surgical instrument makers and their place of business, 67, St. James's-street, and as far as I can remember they were succeeded by Messrs. Louis Blaise and Co. at the same address in the latter part of the "seventies," both firms being instrument makers to St. George's Hospital. "*Pratt*" was an instrument maker in business at 420, Oxford street, London. I possess an aural syringe marked with his name. I may also tell you that my obstetric forceps (Simpson's long) were constructed for me to order by Savigny and Co. in the year 1876.

I am, Sirs, yours faithfully,
EDWARD A. PIGGOTT, L.R.C.P. Edin., &c.

Clare, Suffolk, May 27th, 1905.

PS.—It is very doubtful whether either of the above firms is now in existence.

THE FEE FOR A POLICE SUMMONS.

To the Editors of THE LANCET.

SIRS,—I was recently summoned by a policeman in uniform to attend a case of cut throat a quarter of a mile away. I was paid £1 1*s*. at the inquest and afterwards sent in an account to the chief constable for £1 1s. for attendance at the deceased's house. The chief constable answered.—

> "I understand you were paid a fee for attending this case at the inquest. However, your being summoned to the house .. ... was at the request of the father, to whom I must refer you for any charge you have to make."

Can you tell me if I can claim the fee?

I am, Sirs, yours faithfully,
May 26th, 1905. BAYNHAM.

*** We think that our correspondent is legally entitled to the fee.—ED. L.

ST. HELENS HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I thank you for the very excellent notice you have given to the St. Helens Hospital. You quite understand the 1*d*. a week or the 1s. a day subscriptions do not pay the medical man; these subscriptions do not include medical attendance—most of the patients belong to works or clubs, by whom the medical attendance is provided. The chief features are: 1. A highly trained and most efficient nursing staff, capable of meeting any emergency that occurs until the arrival of medical men. The *telephone greatly facilitates the prompt* attention of professional men. 2. The almost general support in all the works and collieries of the district by means of the 1*d*. a week subscription.

On May 19th about 120 representatives from the various works met in the town hall, St. Helens; the mayor presided, but the meeting was convened at the request of the men themselves. It was unanimously and enthusiastically resolved to subscribe an extra penny per week to wipe out the whole of the outstanding balance of between £3000 and £4000. If this [illegible] ospital work was general throughout th[illegible] would soon be unheard of in connexion [illegible]

I am, Sirs, yours faithfully,
J. FENWICK ALLEN.

Whalley Range, Manchester, May 27th, 1905.

A CURIOUS SUPERSTITION.

To the Editors of THE LANCET.

SIRS,—It is commonly believed amongst the more ignorant inhabitants of the Island of Guernsey that the husband is apt to suffer from illness during the period of his wife's pregnancy and that such illness usually takes the form of boils and abscesses in various parts of the body. I am informed by a member of the Royal Court, Jurat Jno. de Garis, a well-known authority on Guernsey folk-lore and customs, that so widely spread is this belief that in the Guernsey *patois* the verb "cahuchier" means specially to suffer from illness under the above detailed conditions.

The *origin* of such an old established idea, of course, cannot easily be traced but it would be interesting if any of your readers are aware of this superstition being prevalent in any other part of the British Isles or elsewhere and, if so, could they give any further details?

I am, Sirs, yours faithfully,
Guernsey, May 29th, 1905. HY. DRAPER BISHOP.

BEDBOROUGH *v.* DAWSON AND WIFE.

IN the King's Bench Division of the High Court of Justice on May 26th a parlourmaid brought an action against Dr. B. Dawson to recover [illegible] nissal. The defendants de[illegible] that the plaintiff had commit[illegible] d pleaded justification in dismissing the plaintiff. The trial of the action lasted two days and the jury eventually returned a verdict for the defendants; judgment was given accordingly.

◆

T. V.—We cannot speculate as to the condition. A medical man must be consulted and he will decide as to the necessity of inviting the opinion of a specialist.

J. R.—There are scores of such remedies still in existence while scores have died out, their general utility not matching their local fame.

Jas. will find the whole subject discussed in THE LANCET, March 25th, 1905, p. 817.

M.R.C.S.—Yes.

An Address

ON

PLEURISY: ITS PATHOLOGY, DIAGNOSIS, AND TREATMENT.

Delivered at the Gloucester General Infirmary on May 18th, 1905,

BY NORMAN MOORE, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—In my wards at St. Bartholomew's Hospital I have had during the present month eight cases of pleurisy.

CASE 1.—The patient, a strong-looking man, aged 23 years, was admitted on April 25th, with pain on the left side, a short cough causing pain on that side, and shortness of breath on moving his body. Fourteen days before admission he had been seized with pain in the side and cough, and four days before admission he became very short of breath. His left chest when I first saw him was dull except a small apical region. There were no vocal vibrations, no breathing sounds, and no movement on the left side: 90 ounces of clear fluid were withdrawn from his left pleura. His temperature had been raised but remained normal after the paracentesis. The next day a friction sound was audible and some vocal vibrations were present. On May 15th breathing sounds were faintly audible at the left base and no friction sound could be heard.

CASE 2.—This patient was received into the same ward as the previous patient. He was a muscular seaman, aged 25 years, and had signs of pleurisy on his left side. He had had pneumonia three months before. On April 25th he suddenly fell ill and went to bed with a cough causing pain in his left side. The pleural physical signs did not increase and on the next day he had bronchial breathing over the lower lobe of the lung, with increased vocal vibrations. The aspect of the case was that of pneumonia and not of pleurisy. On the sixth day his temperature fell to below normal and the physical signs gradually disappeared afterwards. His arms were tattooed in red and blue—a butterfly, the Royal standard, and a girl's head in a circle of leaves. The work was artistic and had been done in Hong-Kong, where he had been for three years and eight months, returning in November, 1903. The finest tattooing we see in St. Bartholomew's Hospital is that of Japan—delicately drawn butterflies and storks on the wing as good as those of porcelain. That of China comes next and then the Burmese work, often lizards and figures of Buddha and elephants, as well as regimental badges. That done in Hindostan is generally, like native art, slightly altered for the worse by a tendency to imitate European work and resembles in its want of grace the portraits of British officers by native artists which used to be sent home in the days of the East India Company. The tattooing of Malta has less merit still and that of our own ports and camps is the rudest of all.

CASE 3.—The third patient was a carpenter, aged 32 years, from whose chest on the day of his admission 30 ounces of clear fluid were withdrawn by paracentesis. He was admitted with pain in the left side and shortness of breath. The pain had come on suddenly on April 5th and his breath had since grown more and more short while the pain continued. Ten years before he had had pleurisy. His temperature was 100° F. The impulse of the heart was chiefly to be felt to the right of the sternum. There was dulness to the level of the third rib before and behind on the left side, with impaired movement and absence of vocal vibrations. Three days after tapping bronchial breathing was heard over part of the dull area, which had nearly, but not quite, disappeared a fortnight later and had quite disappeared in a further week. A month after admission breathing was still feebler on the left side than on the right and there was very slight general impairment of resonance on the left side. The temperature after an evening rise to from 99° to 99·5° became normal three weeks after admission and throughout had no sudden fall. The improvement after the paracentesis was marked.

CASE 4.—The patient, a man, aged 50 years, had a not very distinct pleural creak at his right apex behind and in front well-marked signs of a cavity. He had double aortic disease. He was admitted with a copious hæmoptysis, had several attacks in the ward, ceased to spit blood after a time, and then again had a recurring hæmoptysis in a copious access of which he died. Post mortem old pleural adhesions over a tuberculous lung with a large apical cavity were found.

CASE 5.—The patient, a stonemason, aged 23 years, was admitted with severe pain in the right side. Two days before he had had a severe rigor, felt very ill, and had pain in the side. His temperature was 103·8° F. and his pulse was full and bounding. He had some cough and scanty watery sputa. In the right axilla and at the base a loud friction sound was to be heard. No bronchial breathing was heard and no rusty sputa appeared. The temperature fell gradually through five days; in the first 24 hours of descent from 104° to 101°. The patient had obvious general emphysema and said that he had had a cough on and off for years.

CASE 6.—In my female ward a patient, aged 38 years, obviously the subject of advanced pulmonary tuberculosis, has a cavity at the left apex with a friction sound over the lower lobe behind, and is another example of pleurisy associated with tuberculosis.

CASE 7.—The seventh patient was an infant, aged 15 months, from the left side of whose chest ten ounces of pus were withdrawn. The prominent symptom was shortness of breath. The lower three-fourths of the child's left back were absolutely dull but a puncture made before admission had failed to demonstrate the presence of pus. The evening temperature was 101° F. Above the angle of the scapula loud bronchial breathing was to be heard behind and over the whole apex in front. The child was so much exhausted that I thought it well merely to feed it from April 7th to 17th and then drew off two ounces of thick pus. The child slept better but the physical signs were scarcely altered. The temperature fell to 99·5° each evening. The sense of resistance on percussion seemed to me increased by the 20th, and on the 22nd as it did not alter I had a rib resected when eight ounces of pus were withdrawn. The breathing sounds became audible, the child regained strength and colour, and the temperature gradually became normal.

CASE 8.—A boy, aged five years, was the eighth patient. He was admitted on March 28th with whooping-cough which he had had since the end of January. The cough was severe, there were many attacks every day, and each was prolonged. After these had moderated, but while they were still numerous (18 a day) a patch of absolute dulness was found at the right base on April 10th. This persisted and I arrived at the conclusion that it was an empyema but postponed an operation till the cough should be less frequent. The patient coughed up a quantity of pure airless pus and the physical signs in two hours were almost normal. For four days a little more pus came up and then no more. Great improvement took place and he is now convalescent. An empyema had pointed into the lung and had been coughed up.

These eight cases present considerable variety and suggest several points for consideration. Why, in the first, a week after the paracentesis, though no fresh fluid was exuded, were the breath sounds still faint over the lower half of the left lung? In the second case, had the attack of pneumonia three months before any relation to pleurisy and pneumonia which came under my care? In the third case, had the pleurisy of ten years before any relation to the attack I have described? How much of the results of the physical examination ought to be set down to the new and how much to the remote attack of pleurisy? In the fourth case, the firmness of the apical adhesions indicated the long duration of tubercle there. In the fifth, why was the temperature so high while the gradual and not sudden fall, the absence of rusty sputum and of bronchial breathing seemed to prove that a true pneumonia was not present? In the sixth, as in the fourth case, the connexion between the tubercle in the lung and the pleural adhesion outside it was plain. What was the explanation of the pus in the seventh case? Did the bronchial breathing indicate that a pneumonia had preceded the empyema? What in the case of whooping-cough was the origin of the pus?

Many other clinical varieties of pleurisy may be observed. A patient of mine with locomotor ataxy became much worse in appearance and very short of breath but without pain. Was this due to cardiac degeneration—he had some signs of aortic disease—or to some other cause? The whole left side of his chest was full of clear fluid. It was let out and a second time tapped. He was in a condition of extreme malnutrition, such as is sometimes the last stage of locomotor ataxy, and after some weeks died. The necropsy showed that he had a true pleurisy with abundant flaky deposit as well as clear fluid, such as would have been painful but for his posterior sclerosis. There was some old calcareous tubercle in his left lung but no recent tubercle was found. A woman, aged 35 years, had absolute dulness over the left side except at a small part of the apex and at the base. The dulness extended to the base in a fortnight but the lower three inches gave a different resistance on percussion, though the absence of resonance was general. This was a dense mediastinal sarcoma extending into the left pleura with a very small effusion into the lowest part of the left pleural sac. A case of probable actinomycosis on the under side of the diaphragm associated with a very small effusion and pleural roughening above it and one of hydatid between the upper and lower lobes of the left lung causing signs indistinguishable from a simple pleurisy are rarer examples which have occurred in my wards.

The experience of my hearers will, I am sure, easily suggest many further variations in detail. This month I saw in the post-mortem room a condition with which I was unfamiliar. It was a left pleural sac, greatly thickened and full of turbid fluid, containing a calcareous deposit as if the whole pleura were one old softened lymphatic gland. The patient was known to have had a pleural effusion for ten years. I wish to add one more rare case. A young man in my ward at St. Bartholomew's Hospital had a patch of dulness at the left base behind with absence of breathing. His temperature was but little raised. He said that his first symptoms began after a sudden exertion and when I chanced to asked if he had anything in his mouth at the time he said, "Yes, a short piece of straw with an ear on it." That disappeared and he thought that he might have dropped it or have breathed it in. The latter proved to be the case. The ear of straw had penetrated the lung and entered the pleural sac and caused an empyema. One day in a violent fit of coughing up came an ear of barley and about four ounces of pus. The patient recovered rapidly. His case was a demonstration of the relation of pleurisy to the outside world.

Let me next set before you a few passages from books. The first is from the most famous physician of ancient Rome. In the treatise "De Locis Affectis" Galen, speaking of pleurisy, says:—

> And this has for its inseparable symptoms an acute fever, a pain as if the parts were overstretched or pricked; the breathing little and frequent; the pulse small; and the artery in a peculiar manner tense and commonly hard. A cough also most commonly accompanies it with a coloured sputum but sometimes without sputum. Such are pleurisies which either carry a man off quickly or come to an end after a long period of time.

The next is from the "Phthisiologia" of Richard Morton, a Doctor of Medicine of Oxford and a Censor in the College of Physicians, who lived close to St. Bartholomew's Hospital in the reigns of Charles II., James II., and William III., and is buried in Christ Church, Newgate-street. There are few collections of cases better worth reading than his.

> A certain youth, living near Cripplegate, in good health and with his viscera certainly sound, whilst at work at his handicraft of a plasterer, by which he earned a comfortable livin by bad luck dropped three nails, which he held in his mouth to u lungs. In consequence of which after irritation he had a profuse hæmoptysis. not know how he at length recovered. It is quite [illegible] were not coughed up. The youth nevertheless for many months was in good health and worked at his trade as before. He did not feel changed in any way for the worse except that from that time forth he had a dry hollow cough and some sense of oppression, neither troubling him much. He believed himself so well that he thought himself fit to take a wife and was married. On the wedding day, whether from more free drinking of wine than usual or from dancing too much (whence the nails, which before lay as if buried, fixed in the substance of the lungs, were moved anew), the unfortunate bridegroom towards evening was seized with dreadful spasms and most acute pain of chest and side with difficult breathing and a dry but very violent cough so that he could not lie down on his bed or take the least sleep. Thus at last he became feverish and seemed to shiver owing to the urgent spasm of the pain. All the remedies of old wives and drug compounders having been tried in vain I was implored on the third day of the illness to come to him. I at once saw that the disease was peri-pneumonic in its nature and I prescribed free bleeding, fomentations and liniments externally, and internally a linctus and pectoral apozem and julep in the antispasmodic waters. These doing little I ordered bleeding again and again. I tried a variety of internal and external remedies before I relieved the wretched patient in the least. The pain being a little relieved I was unable to check the cough and expectoration or to reduce the fever and it seemed to turn from an acute pneumonic fever into a hectic fever. At last from the urgency of the symptoms the patient feverish could sleep and take food be leclined and in a month or five weeks to of phthisis. When his body was opened [illegible] atal nails as if buried in a bed of pus a little below the division of the bronchi and the pleura as it were corroded by pus. I drew off six pints, if I remember right, of this purulent fluid.

Galen it is obvious had observed, as his note of the sputum shows, cases of pleuro-pneumonia in which the prominent symptoms pointed to the pleura: Morton's case shows how an empyema was produced by the passage of foreign bodies from the lung into the pleural cavity.

The explanations of disease and the general pathological theory have changed so much that it often requires a special study before one can be certain what was meant by the hypotheses of old medical writers but their descriptions of cases have often a higher and permanent value. The difficulties of interpreting them are the same as those of the interpretation of cases at the bedside and hence their consideration is a mental exercise of practical value in our training as observers of disease. Books, such as Morton's "Phthisiologia," the "Observationes Medicæ" of Nicholas Tulpius, Wepfer's "Observationes Anatomicæ," Morgagni "De Sedibus et Causis Morborum," Diemerbroek's "De Peste," Andral's "Clinique Médicale," as well as many other writings of less famous authors repay perusal as collections of problems similar in kind to those which we have to try to solve every day. Every man who has published faithfully described cases of disease from his own observation has made a contribution which has a permanent value in medicine.

In the clinical study of a case of disease that endeavour to make out what is taking place in the patient which is our daily work and on our success in which the usefulness of our treatment must depend, there are three stores of knowledge in our minds to which we turn for help, after collecting all the information which can be obtained from the physical examination, the symptoms, and the history of the patient. These are our recollections of cases which we have seen, of cases of which we have read, and of post-mortem examinations.

In this discussion of pleurisy I have dealt with the first two groups and I will now proceed to the third, the collection of facts from the post-mortem room and the laboratory. Dr. S. J. Gee, one of the last writers on pleurisy, in his definition says: "For the last century or more pleurisy has been defined to mean inflammation of the pleural membrane." In what conditions do we meet with this inflammation of the pleural membrane in the post-mortem room? First of all, in every condition in which the lung or a part of it is solid. In lobar pneumonia (pneumococcal) it is always present—every such pneumonia is a pleuro-pneumonia. Pneumococci are present in the lung and in the pleura; leucocytes which solidify the air vesicles are also present in the pleural sac. Tuberculosis, according to the degree of infiltration, is present in both lung and pleura. Pneumonia of diphtheria presents so precisely the appearances, including the pleural roughening, of lobar pneumonia that till the late Professor Kanthack demonstrated its bacterial nature it was supposed to be the same disease. Yet the presence of Klebs-Löffler bacillus establishes its specific character. Pneumonia of pyæmia occurs with streptococci which are also present in the pleura. Pneumonia of plague also occurs in which the cause of consolidation is the bacillus pestis. I have brought with me a specimen recently added to the museum of St. Bartholomew's Hospital—the lung from a case of plague showing the presence of pleurisy. The lung is quite solid; the pleural deposit, though scanty, is obvious on its surface. I cannot avoid dwelling for a little on the reflections which this specimen suggests. 20 years ago to study the plague was to study an obsolete disease. I remember reading in 1889 a chronicle, then printed for the first time, which the editor, Sir Edward Maunde Thompson, had been so good as to give me. The chronicle was written in the reign of Edward III. by Geoffrey le Baker of Swinbrook, an Oxfordshire clergyman, and as a physician the account of the most severe English epidemic of plague struck me. I may venture to read it to you, especially as it mentions Gloucester.

> In the year of Christ, 1349, in the twenty-third year of the King's reign, a general plague spreading from the east of the Indians and Turks infecting a half of our inhabited world, carried off with such loss of life Saracens, Turks, Syrians, Palestinians, and, finally, Greeks, that, driven to it by terror, they decided to accept the faith and the sacraments of Christ. hearing that death did not affright the Christians on this side of the Greek sea more frequently than usual. At length the cruel devastation passing in succession the parts beyond the Alps

and from there to the west [illegible] after its outbreak arrived [illegible] almost all the inhabitants [illegible] living inward, and thence [illegible] Bristol, so that the men of [illegible] to their country, everyone [illegible] [illegible] all pleas in the King's Bench and Common pleas of necessity were stopped. Very few great men died of it. Among them were Lord John of Montgomerie, Captain of Calais, and the Lord of Clistelo; they died in Calais and were buried in London in the church of the Brethren of the Blessed Mary of Mount Carmel. A countless number of common people and a host of monks and nuns and clerics as well, known to God alone, p[illegible] chiefly attac[illegible] anyone dare[illegible] left behind, [illegible] quite well a[illegible] suddenly br[illegible] they were so [illegible] flowed from [illegible] it cleared many country villages completely of every "individual of the human race."

The plague of 1348–49 in England was part of the greatest epidemic which is known in history. It reached Europe from the East by way of Constantinople. The cities of Europe were then much smaller than now, yet 100,000 died from plague in London and 100,000 in Venice, 50,000 in Paris, and 60,000 in Avignon, and so on all over Europe. It lasted a shorter time than the epidemic of the sixth century, which began about 542 and lasted for 52 years, but it was more severe while it lasted. It was followed in England by many more epidemics till that of London in 1665, of which we have all heard. Except a very few isolated cases up to 1679 no more was heard of plague in England till September, 1896, when two cases appeared on a ship from India in the Thames. Since that time other cases have appeared at Glasgow, at Liverpool, and at Leith, but the epidemic has been steadily progressing in India. 30,000 died in the first year (1896) and this year the same number or more have died in a week for many weeks in succession. In 1904 1,040,000 died. This year, from Jan. 1st to April 1st, 474,744 died and in the month of April 215,961. These nine years' of steady increase till numbers greater than those of any previous epidemic, except that of 1348–49, have been reached, make it likely that this epidemic will spread further and it may not improbably attain considerable proportions in Europe.

It is certainly our duty to become acquainted with the symptoms, to understand what is known of the presence of the disease in rats and its being spread by them, to study the method of progress of plague epidemics, and even to know the look of the bacillus. The admirable "Treatise on Plague," by Dr. W. J. R. Simpson, lately published by the Cambridge University Press, contains more information than any other book on the plague. Such a book as Isbrand de Diemerbroek's "De Peste," published in 1646, contains numerous cases simply told and gives a good idea of what may possibly be seen again in some parts of Europe or even in the British Islands, but Dr. Simpson has treated every part of the subject in the fullest way and brings to bear upon records and reports a large personal experience of plague in India, China, and Africa. His book is most interesting and valuable reading on a subject on which, I think, we all ought to know something in view of the vast proportions to which the Indian epidemic has already attained and the scattered cases which have already appeared on our own shores.

To return to pleurisy from this digression on the plague: lobar pneumonia, tuberculosis, pneumonia of diphtheria, pneumonia of pyæmia, and pneumonia of plague, in all of these the whole or part of the lung seems stuffed with the results of the development of micro-organisms but pleurisy of the same nature as the change within the lung is often to be found in broncho-pneumonia and even over very small patches of it if near the surface of the lung. In hæmorrhagic infarction of the lung and [illegible]n the lung pleurisy is always [illegible] interference with the nutrition [illegible]o serious that organisms which would otherwise be breathed out of the lung without settling anywhere find their way through into the pleura and so produce pleurisy. Thus it is easy to see that in each variety the pleura is reached through the respiratory tract. The pneumococcus, the tubercle bacillus, the Klebs-Löffler bacillus, the streptococcus, the plague bacillus may as easily be perceived to have passed from the lung to the pleura as the ear of barley in my patient or the nails in Morton's plasterer. If broncho-pneumonia is extensive there is always some pleurisy; if it is slight there is none; the conclusion that the pleural colony of organisms originates from the intrapulmonary settlement is obvious. Pleurisy with large clear effusion like that of the first case I mentioned in this address, how is it—the simple pleurisy as some would call it—to be explained? Assuredly by a similar invasion of the pleura from the respiratory tract.

What truth is there in the eight aphorism of the fifth book of Hippocrates? "When in pleurisy the chest does not become free from fluid in 14 days an empyema is formed." It is undoubtedly true that the longer a patient has had a pleural effusion the more likely it is to be purulent. The vitality of the serous membrane is diminished, its obstructive power is lessened, and organisms pass more and more freely from the lung into the pleura. Thus the aphorism has a basis of truth, but how about those cases of empyema common in children and occurring, though less often, in adults in which an empyema is clearly of only a few days' duration? A large proportion of these, like that of the seventh case which I described, will be found to have followed a lobar pneumonia of greater or less extent and some are, of course, associated with tubercle.

Here I ought to note that lobar pneumonia in children is often certainly present though no absolute dulness can be discovered and no bronchial breathing heard. One listens day after day expecting physical signs and sputa are not to be expected in a child. The temperature continues high and the breathing rapid. It is impossible to clear the mind from some anxiety lest the case should prove to be one of miliary tuberculosis—in which physical signs are often long in appearing—but on the sixth or seventh day the temperature falls in a few hours to below normal and does not rise again permanently, though sometimes ascending a degree or two on the next day, and the acute condition is past—the case was one of lobar pneumonia. The physician in the times before Laennec would have made the diagnosis of pneumonia (peri-pneumonia as they called it then) without hesitation. Our accurate method of observation by percussion and auscultation makes us doubt in our interpretation of the general aspect of the case. We are right to hold judgment in suspense but are reminded that diagnosis where the lungs are concerned should never be made upon physical signs alone but should be the result of a full consideration, not only of the physical signs but with them, of the patient's general symptoms, in which I include any laboratory observations that can be made, of the history of his illness, and of his own history.

Tubercle most often reaches the pleura from the lung but sometimes seems to find its way from the abdomen, perhaps directly through the diaphragm. A girl, aged four years, was admitted into my ward on June 13th, 1904. She had had measles and whooping-cough at the age of two years. In January, 1904, her abdomen began to swell and in April she had wasted a good deal. On admission the physical signs in her chest were normal; it was repeatedly examined for several months and they continued so. Her abdomen was greatly distended with fluid and measured 24 inches at the umbilicus. On July 5th the swelling had increased and 3 pints 16 ounces of fluid were let out by paracentesis. On July 17th the girth was 27 inches and 5 pints 4 ounces were let out and on Sept. 9th six pints. Laparotomy was then performed by my colleague, Mr. W. MacAdam Eccles. Much fluid was let out and in the right iliac region a large mass of tuberculous glands was found. The disease was undoubtedly tuberculous peritonitis. The distension returned and on Oct. 14th 7 pints 15 ounces of greenish fluid were removed by paracentesis. The child after tapping seemed fairly well, ate well and slept well, and there were no physical signs of disease in the lungs. On Dec. 2nd five pints were removed and on the 22nd six pints. On Jan 16th, 1905, 5 pints 14 ounces were removed. Scattered subcrepitant râles were now audible at the left base—none on the left side. On Feb. 13th 4 pints 14 ounces were withdrawn by paracentesis. On March 2nd a well-marked friction sound was heard in front below the fourth rib and in the right axilla. Breathing sounds were feeble. The friction sound continued. On April 1st paracentesis was again performed and six pints were removed. On April 6th the friction sound was audible over nearly the whole right front of the chest. On April 20th five pints were removed from the abdomen. Friction over the right chest was plain. Bronchial breathing and bronchophony were now to be heard at the right apex behind. From about the middle of March, but not until then, the child seemed going downhill. From Sept. 24th to March 14th the temperature was generally normal or subnormal; after that it often reached 100° or 101° F. It was twice 102° during six weeks and then generally 101° and once 103° during the last fortnight of her life, which ended on May 8th. The post-mortem examination showed extensive tuberculous peritonitis, tuberculous pericarditis, and tuberculous pleurisy on the right side. The lungs contained no tubercle. In this case, therefore, the right pleura seems to have been directly infected from the peritoneum and the pericardium probably from it. The observations of this progress made during life were confirmed post mortem.

Another case of pneumococcal infection was that of a child, aged 11 months, who was admitted in a collapsed state into one of my wards this week and who sank rapidly. A part of the upper lobe of the left lung was solidified and on its pleural surface there was a fine granular deposit. The pericardium was coated with an abundant deposit of lymph and the pericarditis was proved to be pneumococcal. Here it is probable that the infection was from the lung to the pericardium. Vomiting and diarrhœa were present but no evidence of infection in or around the alimentary canal was discoverable. I have placed on the table specimens from this case, the lung and the heart.

The pathological conclusion which I wish to draw is that, excluding traumatic cases, we are to think of pleurisy as an indication of some general morbid condition, and most often of some bacillary infection, and not to imagine that it is a mere affection of the pleura. Have we, in one case, to deal with a manifestation of tuberculosis at a stage when, if recognised, treatment is almost certain to be curative? This may be so not only in the empyemata of children but also in pleurisies of young adults with clear fluid.

The pain in the side which has long been observed, perhaps even before Laennec and auscultation, as a sign preceding the full development of phthisis is a pleurisy, but generally one associated with a permanent tuberculous settlement in the lung and with adhesion. When we find a localised friction sound continuing for many weeks without much advance such tuberculous pleurisy is sure to occur to us, though I remember a promising physician and medical teacher whose life might have been saved had he accepted the view that this was the true nature of a local pleurisy which during several months now and then interfered with his work. A pleurisy with a large clear effusion which is probably rapidly relieved by paracentesis is often dismissed without a thought of tuberculosis.

The conclusion of my observations on the pathology of pleurisy is that we are to take the symptoms and physical signs of pleurisy as evidence of the existence of a condition affecting an important area of the respiratory tract and not merely the covering of the lung.

The diagnosis of pleurisy seems simple; the physical signs—dulness on percussion, immobility, absence of vocal vibrations, and absence of breathing sounds—are well known to everyone; the symptoms—pain on coughing or drawing breath, a marked decubitus sometimes on the affected and sometimes on the unaffected side but generally marked, and rise of temperature—are plain enough, yet I remember a very acute physician saying that he was inclined to estimate the clinical merit of his house physicians by the number of times they did not fail to recognise empyema in children and the number of cases in which it is difficult to be quite certain that a pleurisy is not present or that it is are many. As regards adults I believe the method likely to lead to fewest errors is to begin with the symptoms. The aphorism of Boerhaave (875) is at once an admirable example of his lucidity of statement and a complete collection of the important symptoms of pleurisy.

> A pleurisy is said to be present when a person labours under an acute continual fever with a hard pulse and a sharp pricking inflammatory pain in the side which greatly increases in the act of inspiration, but abates *in expiration, or by holding the breath; also becomes* milder when the breathing is performed by the abdomen chiefly, without *moving the breast*; there is likewise a cough, which is almost incessant, and which exciting great pain is therefore stifled or suppressed by the patient.

The severity of the pain and the way it is produced are striking. The suddenness of its onset is often remarkable. Juvenal says people used to attribute it to the blow of a stone or a dart cast by the gods at the sufferer.

> Præterea lateris vigili cum febre dolorem
> Si coepere pati, missum ad sua corpora morbum
> Infesto credunt a numine: saxa deorum
> Haec et tela putant.

The pain of herpes zoster is as great but it is not made worse by drawing breath and in most cases its onset is less sudden. It is generally preceded by some irritation or uneasiness in the affected area.

The intense cardiac pain which sometimes occurs in children with valvular disease in whom there is no direct evidence of pericarditis or proof of pericardial adhesion, extending as it does over a surface corresponding to a considerable part of the chest wall, may sometimes seem difficult to distinguish from the pain of pleurisy. It often lasts long enough to be more than a mere spasm. A boy, aged seven years, lately in one of my wards had after rheumatic fever with severe endocarditis many such attacks which were sometimes prolonged for half an hour. He was first uneasy, then screamed aloud with pain, and seemed throughout in the greatest distress. After many weeks he ceased to have any more such attacks and was able to go to a convalescent home, with valvular disease but without distress and in fair general condition. In such a case the position of the patient sitting up and leaning forward is unlike that assumed when pleural pain is severe and prolonged observation will always enable one to be sure that the distress has to do with the heart and not with the lungs.

It has often been observed that the onset of the disease is more violent, the rigors more severe, and the temperature higher in lobar pneumonia than in cases of pleurisy even with large effusion. While in lobar pneumonia on the first day the temperature may rise to 103° or even to 104° in a pleurisy it may often not rise much above 101° with a corresponding diminution of general disturbance. Such were the conditions in the first of the cases I described at the beginning of this address. The infection in lobar pneumonia and in such pleurisy is yet in many cases undoubtedly the same. I believe that the cause of the difference is the strength of the infection; the numbers of the force of bacilli which is established in the respiratory tract. Cases of pleurisy now and then occur in adults in which, though no lobar pneumonia is discovered, the onset is severe and the rise of temperature great but in most such cases the pneumococcus is abundant in the lung as well as in the pleura. The pneumococci, as also tubercle bacilli, are difficult to discover in a copious serous effusion and they live with difficulty there, so that there is no such marked change of temperature or crisis when their development comes to an end. This is at least a plausible explanation of the difference in the clinical phenomena of lobar pneumonia and pleurisy not incompatible with the fact that both are the result of pneumococcal infection.

The cough is a symptom often little noticed in simple pleurisy; the patient tries to suppress it in order to avoid pain and the medical attendant concentrates his observation on the relief of the pain. Yet sputa are generally present, however scanty, and aid the differentiation of pleurisy from lobar pleuro-pneumonia. The expression "a dry pleurisy" conveys often the idea that a pleurisy with effusion of lymph but without fluid as well is present, but the expression was used long before the presence or absence of fluid could be proved by percussion and auscultation and referred to the presence or absence of sputa. Boerhaave, in his 867th aphorism, says: "Whenever, with these *symptoms*, there are also incidental or symptomatic spittings from the lungs, the pleurisy is then said to be *humid* or *humoral*, but when discharges by spitting are absent it is then termed *dry*." As to the physical signs, where a great deal of lymph is present and little fluid, bronchial breathing may be heard and vocal vibrations be felt, as I learned in the case of a man at St. Bartholomew's Hospital who died soon after admission and whose physical signs thus pointed to lobar pneumonia, though no pneumonia and only pleurisy was present.

The aspirating needle does not always convey the truth. A patient in St. Bartholomew's Hospital had complete dulness up to the third rib on the right side and some depression of the liver. She was tapped in the fourth interspace and three pints of pus let out. She sank rapidly—it was a huge hepatic abscess which had been tapped. A child had signs of pleurisy on the left side and was tapped and pus let out At the end of a week it died The trocar had reached a purulent pericardial effusion but a contemporaneous empyema at the base surrounded by adhesions had been passed over and remained undrained An effusion containing blood is generally present in diffuse pleural new growth but blood is occasionally present in pleurisy without new growth and may depend on some special form of infection

The diagnosis of pleurisy consists of two important parts—the determination of the situation and physical effects of the effusion which may vary from a little roughening on a small area of lung surface to several pints of pus, and the determination of the nature of the infection Both parts of the diagnosis present many difficulties and both should be fully considered in every case

The treatment of pleurisy may seem to be a subject on which nothing new can be said, yet the difficulties are not few In the seventeenth and eighteenth centuries everyone except the rash and presumptuous Van Helmont agreed that the patient must be bled but there was much controversy as to whether the vein ought to be opened in the arm of the affected side or of the opposite side Hippocrates, Galen, and Celsus were said to recommend the affected side, Aretæus, Ætius, and Cœlius Aurelianus were of the contrary opinion For over 800 years, between the eighth century and the beginning of the sixteenth, or, to put it in another way, during the whole period in which the "Continent," or "Hiber Elhavi," of Muhammad Ibn Zachariah el Rázi, more often called, Abu Bekr or Rhazes, was a text book of authority, it was almost the invariable practice of physicians to have the patient bled from the arm of the opposite side to that on which the pain was Then came the revival of learning which opened so many books of the ancient world to the West Homer was printed at Florence and all the treasures of Greek philosophy and literature were placed before men—Plato, and the tragedians, and Thucydides and the true texts of Hippocrates and of Galen, and amidst these great contributions to the intellectual advantages of all Europe it was discovered that Galen advised bleeding from the arm of the affected side Dr Peter Brissot in Paris, early in the reign of our Henry VIII, pointed this out in lectures, used it, as is said, with advantage, and persuaded many physicians to adopt the method of Galen The reform

t with opposition and the dis-

was carried on in the University

against Galen's view Charles V

was asked to forbid as king and emperor the practice of bleeding on the affected side For nearly 200 years the controversy continued and probably traces of it may be found in medical writings or in popular belief up to the time when, to the great advantage of patients, bleeding was altogether given up in pleurisy

In the very earliest times, however, we find that a form of treatment which persists to this day was in use the application, namely, of warm fomentations to the painful side Hippocrates recommends a bladder containing hot water or a warm sponge or bags containing heated bran or barley meal moistened with vinegar

The island of St Bartholomew, in the Tiber, where now stands the church of St Bartholomew, was once occupied by a temple of Æsculapius, the monolithic pillars of which are now those of the church, a building of which the tower belongs to the eleventh century Here, as Hieronymus Mercurialis states in the first book of his "De Arte Gymnastica" (Book I, cap i), published in 1573, a marble tablet was found with a Greek inscription relating how one Luke, having a severe pleurisy, was advised in the Temple of Æsculapius to take ashes from the altar, to mix them with wine, and to apply them to the painful side, a course which he followed and was cured and so put up this clinical record and received public congratulation External applications are a better way of relieving the pain, in my opinion, than the u e of morphine and if skilfully applied seldom fail to do so quickly

Paracentesis is now universally practised in England but there are several matters in connexion with it which deserve a good deal of consideration

there from a large non purulent

in the light of experience see

to occur I have only known one death directly due to a large non purulent effusion The patient was a man with aneurysm of the aorta who had been kept on his back for some three months One afternoon he suddenly sat up in bed and almost immediately died It was naturally imagined that his aneurysm had burst within his chest The necropsy showed that this was not the case and that he had a large unsuspected clear effusion into his left pleura and that the sudden change of position was the probable explanation of his death On the other hand, I remember a woman who with five pints of fluid in the right pleural cavity walked to the top of a lofty staircase without injury The long time which often elapses before the breathing sounds and the percussion note are normal on the affected side in cases of pleurisy of short duration with clear effusion suggests that a more real danger is the permanent binding down of the lung or its collapse Such collapse when complete constitutes a most serious and long continued danger to the patient His pleura may become a huge abscess sac, as in the case of the chalky effusion already mentioned Another example was that of a private in the Guards, aged 24 years, whom I had under my care and who had had such a sac for about seven months before admission to the hospital His lung was completely airless, bound up against the vertebræ near the root He died exhausted after an operation for his relief A man, aged 22 years, after an attack of pleurisy expectorated in the last week of May, 1892, a pint of pus This was immediately followed by left pneumothorax but after resection of the tenth left rib he recovered with a good deal of contraction of the side

The case of Frederick Prince of Wales, son of George II, as it is related in the diary of his friend, Lord Melcombe Regis, illustrates another danger associated with empyema, suffocation, after it has burst into the lung

House at three o c

A large clear effusion is best got rid of by paracentesis and if a second large effusion occur it should be let out and then generally the patient will recover Now and then a third tapping is necessary A man, aged 32 years, came under my care in St Bartholomew s Hospital with a history of some signs of pleurisy for two months The lower part of the right side was dull and 52 ounces of clear fluid were let out In about five weeks the pleura again contained fluid, 84 ounces were let out and a fortnight later 75 ounces, and then there was no further effusion He became convalescent and had no dyspnœa when he left

Paracentesis is not always without dangers A man in my ward at St Bartholomew s Hospital, aged 59 years, who had a dense new growth in his liver mesentery, pleuræ, and kidneys, and within his cranium (right frontal sinus) was tapped several times for ascites and after three months had a large effusion in the left pleura His dyspnœa increased so much that paracentesis was performed in the ninth left intercostal space A few ounces of clear serum came out followed by serum more and more blood stained and then by pure blood The cannula was withdrawn, a quarter of an hour later the patient s pulse was very feeble and grew worse and he died an hour later The post-mortem examination showed that the intercostal artery in the ninth space had been punctured and the left pleura contained 20 ounces of blood clot and 36 ounces of dark blood stained fluid and liquid blood This is the only example of death from wounding of an intercostal artery in paracentesis thoracis which I have seen Another death from hæmorrhage into the pleura was of a different kind The patient was a carman, aged 28 years, who was admitted on Feb 16th, 1905 and who had recently had pneumonia of the right lung Nearly the whole right side was dull except the apical region The patient looked extremely ill and his complexion was dusky His temperature was never normal and every evening rose to 101° or 102°. On Feb. 21st a drachm of pus containing diplococci (encapsuled) was withdrawn from the right axilla. Next day an inch of the sixth rib in the mid-axillary line was excised and two and a half pints of pus came out. More blood than usual appeared. On succeeding days the discharge was free but the temperature continued to be raised. On March 10th a piece of rib was excised in the post-axillary line to obtain better drainage. No further collection of pus was discovered. On March 15th much bleeding occurred and the openings were plugged with gauze. Whenever the plugging was removed bleeding took place. The patient also coughed up much bright-red blood. These conditions continued till March 26th when he died after a profuse hæmorrhage. The post-mortem examination showed that the hæmorrhage was from the lung which had broken down over a considerable surface and which was probably in a condition of necrosis when the empyema was first tapped.

With these rare examples I will conclude this collection of observations on pleurisy. As regards its pathology the propositions which I have endeavoured to maintain are the following. 1. That, apart from injuries, pleurisy is to be regarded as a part of a condition which has generally begun in the respiratory tract, but sometimes in the pericardium (especially in rheumatic fever), and now and then in the peritoneum, and that the origin ought always to be carefully investigated. 2. That empyema is a frequent result of lobar pneumonia and also of tubercle. 3. That large non-purulent effusions are due to pneumococcal or tuberculous affection. 4. That tubercle reaches the pleura from the lung in most cases and in a few from the peritoneum.

As regards diagnosis I wish chiefly to insist that it should take a wide survey of the origin of the disease and not be confined to the interpretation of physical signs. As regards treatment I agree with those who are in favour of letting out all large serous effusions and all empyemata and in the latter case I am more and more inclined to favour the method of resection of a piece of rib as procuring better drainage and therefore more speedy recovery.

There is another and more general principle of treatment which follows from what I have said as to the pathology and diagnosis of pleurisy. It is that the patient should be kept under observation till he may be considered free from the condition of which the pleurisy was the most prominent manifestation. It is in this direction of encouraging prolonged observation that we may expect modern pathology to affect treatment, greatly to the benefit of patients. Almost the only acute disease in which at present we keep patients long enough under control is enteric fever. In rheumatic fever I am convinced that rest in bed in all cases for from three to four weeks after the temperature is normal would lead to a diminished percentage of permanent valvular disease and that it is only by a prolonged temperature chart that we can arrive at certainty as to the cessation of the endocarditis. In pleurisy regulations as regards fresh air and diet followed out in all cases would often prevent the development of permanent tuberculosis later in life.

"Principiis obsta" is an often repeated exhortation. Every year of medical progress gives us more opportunities of applying it. Treatment is necessarily prolonged in the particular illness but attacks of illness may thus be made fewer in number and the melancholy end of the verse is never experienced—

"Sero medicina paratur,
Cum mala per longas convaluere moras."

SOME NOTES ON PLAGUE.

BY ALEXANDER M. ELLIOT, M.B., C.M. EDIN.,
LATE SPECIAL PLAGUE OFFICER, BOMBAY GOVERNMENT.

DURING the past few years I have come in contact with plague in nine different districts in India. Close on 3000 cases have come directly under my actual control and about another 5000 have come indirectly under my observation. This disease has so far baffled every effort to stamp it out. It has upset all laws that govern most diseases. It has shown a variability in type, in the manner of its rise and fall, and in its choice of climate and soil that no other disease can lay claim to.

Plague is caused by a specific micro-organism, the plague bacillus, which shows a pleomorphism unique amongst bacilli. This was discovered by Kitasato in 1894 and by Yersin about the same time. In young buboes it is found in almost pure culture, but as suppuration supervenes the bacillus begins to disappear and when suppuration is fully established the bacillus is seldom found. Personally I have never found it in fully suppurating buboes. This disappearance in the above circumstances is an interesting fact and will be dealt with subsequently. The bacillus is also found in the internal organs. Excluding the lymphatic system I find that it occurs in greatest numbers in the spleen, then the liver, the cavities of the heart, the lungs, and lastly the kidneys. In all types of the disease the spleen comes easily first. In pneumonic cases of course the lungs are highly congested and full of bacilli, but in other types the lungs are not infected to any great degree. In what has been called the "alimentary form" I have found the bile in the gall-bladder full of plague bacilli. Smears from the spleen or the liver show the bacillus in the form of a short organism with rounded ends; in the same smear one finds cocci and diplococci-like forms. Motility is a character that is denied this bacillus by many. My first note as to its motility was made in 1900. I have since that date examined so many specimens in which marked motility was present that I am certain that the plague bacillus does at times present this character. I say "at times," as it is not in every specimen that I have found motility. It is more noticeable in those cases which I mark fulminant, that is, which die within 24 hours from the onset. So far I have not succeeded in staining flagella. Smears from human organs do not show a bipolar staining of all the plague bacilli, but in rats dead from plague it is more usual to find the greater number of plague bacilli giving the bipolar character. Even this character, however, is not uniform, for bacilli are met with showing all degrees of polar areas. The bacillus does not stain when treated by Gram's method, whether it be taken from a bubo, from an internal organ, or from the blood.

Bitter places the plague bacillus amongst the "septicæmic group." Of the correctness of this there can be little doubt, I think. Septicæmic organisms have the following general characters. When a susceptible animal is inoculated with a minimum quantity of the bacterial culture the organism passes at once into the blood and commences to grow with great rapidity; it finds its pabulum there and it produces a septicæmia. At times inoculation does not result in an immediate invasion of the blood stream. The bacillus requires some foci in which to develop. From these foci the toxic products enter the blood and it is not until a few hours before death that the bacillus is found in the blood. This is really, first, a toxæmia. Examples are supplied by anthrax and by plague. There are all degrees of susceptibility. Commencing with the most susceptible animal, after inoculation of a minute quantity there is no local reaction and the bacillus seems to pass directly into the blood stream but a point is soon reached where a local reaction on the animal's part occurs. A battle takes place between the invading bacillus and the preservative elements present in the animal. The invading forces gain the day, the preservative elements are overcome, being present in a small degree, a general infection takes place, and death is the result. At last a group is arrived at in which this organism so deadly for others is no longer so for this. It only produces a mild local reaction or perhaps no reaction at all. So it is with plague. Rats show susceptibility in the highest degree. No local lesion can be found in the animal, which dies from a virulent septicæmia. As regards man's relationship to plague, I have come to the conclusion that in man there are two degrees of susceptibility, which degrees depend mainly on the source of infection. One of them is that susceptibility in the highest degree which produces pneumonic and septicæmic cases. Secondly, there is a degree of susceptibility which produces the bubonic cases. This is the stage characterised by local reaction and toxæmia which may end fatally or may go on to recovery.

A peculiarity in plague is that when that point is reached in which local reactions are necessary it does not happen, as in diseases caused by other septicæmic microbes, that the local reaction takes place at the site of inoculation but that it is the nearest group of lymphatic glands which shows the reaction. The seat of election with plague is the lymphatic system. In every case of plague one or other group of glands is infected, no matter how short the history—be it only 20 hours. I give two cases from my notes. The first of these patients was a watchman, aged 20 years. He was on inspection parade at 8 A.M. but did not report anything wrong. I inspected the lines at 9 A.M. and saw this man but he made no complaint. At 10.30 A.M. I returned to the hospital and was told that a watchman had been admitted a few minutes previously. The house surgeon could not make much out of him so he asked me to see him. He was a strong healthy young man in the same condition as when I had seen him on my rounds. When asked why he had not "reported ill" before he said that beyond feeling a little giddy he was perfectly fit for duty so he thought that it might pass off. His temperature and pulse were normal, his tongue was clean, and he had no pain anywhere. I was on the point of sending him back to duty but as his eyes seemed somewhat heavy and plague was epidemic at the time I took him in for observation. At 12 noon his temperature was 101° F. At 3 P.M. it was 106° and he was dead at 3.30 P.M. At the necropsy numerous small petechiæ were found all over the mesentery, the small and large intestines, the abdominal surface of the diaphragm, and the heart. The mucous membrane of the gastro-intestinal tract was greatly congested. The mesenteric glands were enlarged. The spleen and liver were of normal size but congested; the gall-bladder was distended. The axillary and inguinal glands were normal. Smears taken from the spleen and mesenteric glands gave almost pure cultures of plague bacilli. Similar results were obtained from the liver and the gall-bladder, the latter having other bacilli. Blood taken from the heart showed bacilli but not many and smears from the lungs were practically negative, very few bacilli being found in them.

The second patient was a syce, aged 36 years. He was working at 8 A.M. and came to the hospital at 9.30 feeling sick and giddy. His temperature was normal, his tongue was coated, his eyes were bright, and his pulse-rate was 80. At 12 noon his temperature was 104°, his pulse-rate was 140, and he died at 4.30 P.M. The post-mortem appearances were almost the same as in the last case. These men were of different caste and lived four miles apart. In a series of over 400 necropsies I have never yet found one case in which some group of glands was not infected.

As stated above, animals are susceptible to plague in varying degrees, rats coming first, then guinea-pigs, and so on. I wish to mention here some experiments made by me on some domestic animals. My reasons for this are that in an article published in 1903 Dr. Simpson emphatically states that fowls, pigeons, ducks, and turkeys are not only susceptible to plague but are a means of conveying it to human beings. The point is one of much importance and one that ought to be settled. Throughout the past five years I have kept careful note as to any abnormal death-rate amongst domestic animals before, during, or after a plague epidemic. In no district could I get any information that might lead one to suppose that fowls, pigeons, or ducks contracted plague. In 1900 I experimented on pigeons with negative results. In 1903 I repeated the experiments on a larger scale. I took one dozen healthy pigeons and half a dozen fowls. I kept them shut up in coops for three weeks so as to accustom the birds to their close quarters. Then I commenced as follows. Into the peritoneal cavity of two pigeons I injected one cubic centimetre of a 24 hours culture of plague bacilli. The same quantity was injected into the crops of two others. I repeated on four other birds the same but increased the dose to three cubic centimetres. With the fowls I injected two cubic centimetres into the peritoneal cavity of three. To one I gave two cubic centimetres beneath the wing and two more got three cubic centimetres into the crop. In each case I made control experiments with rats and guinea-pigs. All the control animals died from plague within five days. Daily I examined the droppings for any signs of what might be plague bacilli. At the end of three month all the birds were still alive, not one of them having shown any symptoms of being incommoded by the inoculation. After seeing the Hong-Kong report I decided to make further observations. I commenced with 12 pigeons and 12 fowls. To some I gave two cubic centimetres, to some as much as five cubic centimetres, and two fowls I fed at odd times on plague-infected rats and portions of organs. It is now 12 months since these birds were inoculated but they are all alive to-day and some of the pigeons have been breeding. None showed symptoms of indisposition. One pigeon drooped for a few days about three weeks after the inoculation but was never off its food.

I find that the various commissions which came out to India place pigeons amongst those animals which are not susceptible to plague. The following are some septicæmic diseases in the lower animals which require to be kept in mind by those who are on the watch for plague.

1. *Septicæmia hæmorrhagica.*—This disease is also known as fowl cholera, hog cholera, or rabbit septicæmia. The specific bacillus is widely distributed; it is found in impure water and in putrefying infusions. Its morphological characters are as follows: it has short, rounded ends; it is 1 μ to 4 μ long and 0·6 μ to 0·7 μ broad; it occurs in pairs, singly, or in chains of four or more; staining is usually bipolar; it does not stain when treated by Gram's method; it is non-motile and non-liquefying; it grows best [illegible]

2. *Duck cholera.*—The bacillus of this disease is non-pathogenic for fowls and pigeons. Its behaviour on staining, &c., is similar to that of the preceding bacillus.

3. *Hog cholera.*—The characters are the same as above, except that the bacillus is motile and the colonies are larger.

4. *Swine plague.*—The bacillus exhibits bipolar staining; it is flagellated and motile: it does not stain when treated by Gram's method.

5. *Bacillus agrigenus.*—This organism is found in soil and is similar to that of fowl cholera.

On comparing the above organisms with the plague bacillus it is obvious that any of them, and especially those in Group 1, might be easily mistaken for the plague bacillus. None of the above give stalactite formations but the plague bacillus does.

Cats are susceptible to plague and may convey it to man. Information was brought that plague had broken out in a village some six miles off where there had been a slight outbreak two years previously but none since. I rode to the village and was told that two cases had occurred in the same house which was first infected two years ago. I was also informed that no rats had been found in the village. One of the villagers said that his cat had not been well for two days and that it had a swelling in its neck. This cat, with which was a kitten about seven weeks old, had a swelling on the left side of its neck which was tender to the touch. The post-mortem appearances were as follows. The submaxillary glands were enlarged and inflamed and one was breaking down in its centre. The surrounding tissues were infiltrated with a sero-sanguineous fluid. Smears from the glands and surrounding parts showed staphylococci, streptococci, and numerous bacilli which gave bipolar staining. The spleen was congested and smears taken from it (but not the blood from the heart) showed the bipolar stained bacilli. Plates were made and a bacillus was isolated which corresponded in every way with the characters shown by the plague bacillus. The bacillus was motile but not actively so. A guinea-pig inoculated with one cubic centimetre of a 24 hours' culture died in four days from plague. A rat was inoculated with plague from a human case and died in four days. Its internal organs were given to a third cat. Two days after eating this material the cat showed signs of violent gastro-intestinal disturbance. Its stools were slimy, copious, and showed bacilli with bipolar staining but I was unable to isolate them. The cat died in ten days and it was then found that the whole gastro-intestinal tract was much inflamed with here and there patches of ulceration. All the internal organs were congested and the kidneys had small hæmorrhages into them. The bladder was distended and in the urine I found bacilli giving bipolar staining. Cultures inoculated into rats killed these animals in two days and similar bacilli were obtained from their dead bodies.

Some three months afterwards I was asked to see a man who was suffering from plague. He lived alone and his house was several hundre [illegible] He died and on the next [illegible]; it died during the night and the [illegible] and the characteristics of the bacilli found in it were similar to those mentioned in the above case.

The most important thing to discover is the behaviour of the bacillus during the quiescent stage. In 1900 the following query was made in my notes. "Does the plague bacillus exist as a saprophytic microbe as well as a parasitic one? Would this account for its recrudescence?" Recently the following experiment was made. It is given for what it is worth.

In November, 1904, a case of plague occurred in a miner's hut. These huts measure 9 feet by 12 feet by 10 feet. They are made of tatties on a frame and have a zinc roof. I saw the hut and its occupants at 11 A.M. At 2 P.M. the body of the wife of the man who occupied this hut was brought up for post-mortem examination. The history of the case was to the effect that she had vomited once or twice during the previous night and felt giddy. In the morning she did not feel well but kept to her work. She had died from plague. The flooring of the hut was dug up to the depth of six inches. This was brought to the laboratory and placed in a tin-lined box measuring 4 feet by 2 feet by 3 feet. One foot of wire netting was nailed on in front. The soil was then left untouched for one month. Then four rats were caught from an uninfected area and placed in this box. They were fed on boiled gram. For three weeks all went well. Then one morning I found that the smallest of the rats was dead. In three days' time another had died and in 12 days from the death of the first the four rats had died. They all died from plague. Two days after the last death a guinea-pig was placed in this box; in *five days it had died from plague. I am not yet prepared to* discuss this matter. I hope to do so at some future date when I may have further material to deal with.

In the communication of plague to a susceptible individual the channels of infection are: (1) the skin and mucous membrane; (2) the alimentary canal; and (3) the respiratory organs. Before dealing with these I would like to note a few facts about the lymphatic system. There are two sets of lymphatics—namely, the superficial and the deep. In the limbs those of the superficial set are more abundant upon the inner and flexor surfaces than upon the outer and extensor surfaces. They are especially numerous at the junction of the skin and mucous membranes. The deep set accompanies the blood-vessels. There is no communication between the two sets except where they empty into the same node—i.e., gland. They ultimately end in veins. The lymph mixes with venous blood. The framework of the lymph nodes or glands is adenoid reticular tissue having in its meshes irregular masses of leucocytes. This tissue presents several different forms according to the degree of compactness, some being firm, well defined, and encapsuled, some being diffuse, and some in an intermediate stage. The following varieties may be specified. 1. Diffuse lymphadenoid tissue is found in the mucous membrane of the intestine. It is a mere network of adenoid reticular tissue inclosing leucocytes. 2. In the submucous or subserous membrane there are small distinctly defined masses which are the solitary glands of the intestine. 3. The agminated glands are each a group of two. 4. More distinct collections of lymphadenoid tissue with a well-marked capsule are seen in small depressions of the mucous membrane in the tongue, the tonsils, and the pharynx. 5. Unlike the above, the lymph nodes are not connected with a mucous surface, but have a distinct capsule and occur in the course of lymph vessels.

All nodes, except the superficial inguinals, are situated beneath the deep fascia though not under its immediate covering. Each node or group of nodes receives its lymph from fairly-well defined areas or parts but at the periphery of these areas there is well-marked inosculation of the neighbouring vessels. Members in each group communicate and each group has communication with other groups. The nodes or glands of the lower extremities may be classified as follows, according to their region: (1) the superficial inguinal, (2) the deep inguinal, (3) the popliteal, and (4) the gluteal. The superficial inguinal glands are divided into two sets—namely, the superior or oblique and the inferior or vertical. The superior or oblique consists of three groups—the external, the middle, and the internal. They collect lymph from the integuments of the buttocks, from the skin round the anus, from the lower and outer part of the back above the buttocks, from the penis and the abdomen below the navel, from the distal portion of the urethra in both sexes, and from the vulva and lower part of the vagina. The scrotum and superficial portion of the perineum often drain into this set. The inferior set is situated at the saphenous opening. Lymph flows to this set from the superficial part of the thigh, from the entire leg and foot except the outer side, and from the scrotum and integuments of the perineum. The superficial nodes discharge partly into the deep and partly into the external iliacs. The popliteal nodes collect lymph from the outer side of the leg and foot and the same parts of the deep structures. The deep inguinal nodes lie round the upper part of the artery and vein and get their lymph from the superficial nodes and deep structures of the greater part of the leg. The gluteal nodes collect lymph from the deep parts of the buttocks. The groups of nodes or glands in other parts of the body need no special mention for my purpose.

Referring to my notes I find that inguinal buboes occur more frequently in adult males than in women or children. My own observations also give a much higher percentage of inguinal buboes as primarily occurring in the superior or oblique group of inguinal glands. Once the disease is established the inferior, or what is termed the femoral, group will be found to be infected. I have examined many statistics made by native hospital assistants, which place the femoral bubo before the inguinal. I have asked some of these gentlemen to keep records for me and unknown to them I have made my own observations. I prefer my own observations. I find that inguinal buboes are commoner in women than in children, and in women it is the superior group that shows the higher percentage of primary infection. With axillary buboes women show a higher percentage than *either men or children, but here children approach them* very closely. With cervical buboes—that is, buboes occurring above the root of the neck—the greatest percentage occurs amongst children; women come next, and men last of all. Why should one group of glands be more susceptible in men than in children? Why should all groups not suffer alike?

One of the first things that fixed my attention on landing in India was the peculiar posture taken by a native man when sitting. His perineal region and adjacent parts are brought in very close proximity to the ground. His loin cloths are constantly sweeping up dirt and other matter from the soil. The skin of the fork and on the internal parts of the thigh is in a more or less sodden condition. Tinea circinata is found in 90 per cent. of the natives, especially in the scrotal and inguinal regions. It is the habit of many castes to have the pubes shaved; this renders that part liable to cuts. All these points invite attention to this region rather than to the foot. A native's foot and leg are, moreover, provided by nature with a covering that would defy most insects. Women and children when sitting do not assume the same position as the men. Women are much more on the move, they have not the time to squat down, and when they do it is not done exactly as a man does. Children, again, may squat for a few seconds with their perineal region close to the ground, but their usual state is one of movement, they are either running or crawling about. If the leg and foot are the regions most liable to infection why is there not a preponderance of buboes in the inguinal region amongst women and children in whom there is a more delicate condition of the skin covering the leg and the foot than among the men? May it not be due to the above facts? There are various other causes which need no detailing to the medical mind that render those regions more liable to infection.

I have said that axillary buboes are more common in women than in men. It is only necessary to look at one group of glands—namely, the pectoral group, that lie along the border of the pectoral muscles. They drain an area comprising the mamma and the abdominal surface above the navel. All the groups in this region communicate very freely. The axilla is a spot where dirt can easily accumulate. Profuse perspiration usually goes on there. Amongst some castes the axillary hairs are shaved off or pulled out by means of forceps. This latter performance nearly always leaves one or more bleeding points. The woman's nipple and the surrounding skin are liable to cuts, scratches, or other abrasions. She suckles her children until they are two or three years old; perhaps she suckles one or more during this period. Again, she wears a kind of bolero, close fitting, in most cases far from clean. If she wants to wipe her fingers she instinctively does it on this garment, no matter what she has touched. Here, then, we find reasons that may account for the axillary bubo being commoner amongst women than amongst men.

With regard to cervical buboes the greatest percentage occurs amongst children. Is this to be accounted for by the fact that a child's first instinct is to put all things in its mouth? A child's skin is much more tender and liable to be cut and scratched than an adult's. Why, then, do the inguinal and the axillary regions not show a larger percentage of buboes than the cervical region? I venture to give the above as a possible reason. The mucous membrane is more delicate; there are two periods of dentition; these periods last over several years and it is during these years that cervical buboes are most numerous.

To illustrate the above arguments three cases are given. In the first the scene is a small hut where a man lies on the floor suffering from pneumonic plague. He is expectorating in all directions. Beside him sits his brother or some friend who from time to time wipes the patient's lips with his nether garment or wipes up some of the expectoration that may have fallen near. I have seen him do this with his fingers and then wipe them between his legs. In the course of a week this man had an inguinal bubo; it may be the inferior group but more often is it the superior group that is first infected. In the second case the scene is as above but it is a woman who is ill with plague and her sister or friend sits near. She performs the same kind attentions as the man did but she wipes her fingers under her arms—i.e., in the axilla. In the course of a week she has developed plague with an axillary bubo. In the third case the scene is the same, or it may be in a hospital. A child is crawling round the floor, either sweeping it with a chupattie or picking up odds and ends and placing them in his mouth. In a few days the child has plague with a cervical bubo. I have seen the above happen again and again.

I am of opinion that patients may contract plague through the alimentary system—namely, by means of contaminated food. If a rat is fed on some plague infected material it dies from plague. If some gram rubbed up with the juice expressed from a plague gland or spleen is given to a guinea-pig the guinea-pig dies from plague. In the case of the human subject no such direct evidence is obtainable, but from several post-mortem examinations on patients who died within 24 hours from the time of attack, patients in whom the only symptom was an acute diarrhœa coming on suddenly and ending fatally in a few hours, one is driven to believe that the alimentary canal is a source of infection. If it is so for rats and guinea-pigs why should it not be for man? Post-mortem examinations on such cases show a marked injection of the solitary glands in the small intestine. Plague bacilli are found in these glands and the neighbouring mesenteric glands are likewise greatly enlarged and injected with plague bacilli in them.

When the respiratory system is considered it is more difficult to account for the primary channel of entrance. Cases of pneumonic plague are not met with in every epidemic. In the same locality one or two years may pass with few if any cases recorded; then the pneumonic type may be the prevailing one in the next epidemic. But in this type no matter how soon death supervenes I have never failed to find the bronchial and mediastinal glands infected.

The above three channels of infection give rise to three types of the disease—namely, the bubonic, the pneumonic, and the alimentary. Either of these may take on a septicæmic form and death occurs from an acute septicæmia. Numerous other types are mentioned in some text-books, but if symptoms are taken as the standard of types the latter can be multiplied indefinitely. On looking at the death-rate in each of the above types one naturally wonders why it should be greater in the last two forms. Are there, in other words, an acute, a subacute, and a chronic form of the bacillus? From the virulent and rapid rise of an epidemic to its mild and gradual decline one is forced into the conclusion that the plague bacillus in its passage from man to man probably undergoes a gradual attenuation, ultimately assuming the chronic form, which may perhaps after a more or less extended period of quiescence take on active and virulent properties. But this will not account for the difference in death-rates.

I am inclined to think that there are two forms of the plague bacillus—namely, the acute and the chronic. The latter continues the disease from one epidemic to the other, while the former gives the three types above mentioned, each type being entirely dependent on the channel of entrance, and the difference in death-rates being to a great extent dependent on the group or groups of glands primarily infected. I think it will be admitted that in bubonic plague the gravity of the disease is greater when axillary and cervical glands are infected than when inguinal glands are attacked. At least it is my experience that, as a rule, inguinal bubonic plague is more likely to terminate in recovery than axillary or cervical bubonic plague. The reason for this is no doubt the position of the inguinal glands. They are further away from the central nervous system, they are more or less isolated, and they communicate with the external iliacs alone. The channels of infection when these glands are the primary seat of infection are few. In the upper region of the body there is a free communication not only between each individual gland but between each and every group of glands, so that as soon as one group becomes infected numerous others in close proximity will become so almost at once. The efferents of all these groups discharge into the right lymphatic duct or into the thoracic duct.

A reference to the notes on the lymphatic system will show that there are five kinds of nodes, arranged according to their density. In other words, there are so many kinds of sieves of varying degree in meshwork. In the intestines there are three sets of glands with open network. There is nothing in these glands to prevent easy transmission of material through them. They have no capsule like the inguinals; they are less compact. In fact, they are sieves with a large meshwork. A person swallows some plague-infected food and the plague bacilli pass at once into the general system, producing an acute septicæmia and terminating rapidly. The plague bacillus is not arrested by these glands, for they are lymph glands, there is no primary toxæmia but a true septicæmia, and the plague bacillus is always found in blood from the finger. As soon as the patient complains of feeling ill evidence of his illness will be found in his blood. It would not be wrong to describe this as septicæmic plague but the chief symptom is a violent diarrhœa, the source of infection is the alimentary canal, and septicæmia is not confined to this type alone, for it may accompany a bubonic attack. Here, again, it is more common to find that septicæmia follows on bubonic plague when the axillary and cervical glands are infected than when the inguinal glands are the seat of the disease. So that leaving out such predisposing causes as low state of health, bad food, overcrowding, &c., I venture to state that the virulence of plague depends to a marked degree on the first group of glands which it has to pass through.

That most important question as to how plague is conveyed from man to man is one that will be dealt with in a subsequent paper. For the present I shall merely state with reference to the relationship of rat and man that we have no authentic evidence to show that previously to a first outbreak [illegible] noted death-rate amongst rats [illegible] that any dead rats were found. [illegible] in these villages dead rats were found before human beings were attacked. I have a record of some 20 villages which I visited immediately on hearing of the first case of plague. No dead rats had been seen and the source of infection was in each case traced to other villages.

With respect to the treatment of patients suffering from plague, cardiac stimulants sum up the whole question at the present moment. There can be little doubt that if the unfortunate native and his relatives could be made to under- [illegible] llow any attempt to rise [illegible] cases of plague would [illegible] arly part of this paper I mentioned the fact that as suppuration advances the plague bacillus disappears. Why does this disappearance take place? Is the presence of stapylococci or of streptococci inimical to the growth of the plague bacillus? If so, would it be out of place to bring about suppuration as soon as a bubonic case is admitted in the wards? I make the suggestion. Arguing on the fact that the plague bacillus belongs to the streptococcus group I commenced to treat early and serious cases of plague with inoculations of antistreptococcic serum. Out of 21 cases so treated there were 13 recoveries. For reasons that need not be mentioned I had to discontinue the treatment, but the results are encouraging and might be tried by others.

In 1902, after the above experiments were made, I came across the following observation in the *Edinburgh Medical Journal* for April, 1806: "Before the army left Syria a great number of soldiers were attacked by plague. It seldom attacked wounded men; and scarcely an instance of man being attacked by it whilst wounds were in a suppurative stage, though many were infected as soon as their wounds were healed." This statement was made more than a century ago—namely, in 1804 by the celebrated French surgeon Baron Larrey, chirurgien en chef de l'armée d'orient.

Champion Reef, Mysore State, India.

THE CHEMICAL EXAMINATION OF THE GASTRIC CONTENTS, WITH AN ACCURATE CLINICAL METHOD OF DETERMINING THE "ACTIVE" HYDROCHLORIC ACID.

BY W. H. WILLCOX, M.D., B.Sc. LOND., M.R.C.P. LOND., F.I.C.,
LECTURER ON PATHOLOGICAL CHEMISTRY AND MEDICAL REGISTRAR AT ST. MARY'S HOSPITAL, W.

THE attention which is being paid at the present time to the surgical aspect of diseases of the stomach is a sufficient excuse for the title of this paper. During the last two years great strides have been made in the operative treatment of various gastric complaints and there is no doubt that further advances will be made in this direction in the immediate future. It is impossible, for example, to exaggerate the importance of an early diagnosis in cases of gastric carcinoma. The diagnosis is usually deferred until a definite mass can be felt. An operation is then performed but too often other structures are found to be secondarily involved, so that the surgeon must perforce be content with the palliative operation of gastro-enterostomy when an earlier diagnosis might have enabled the entire diseased part to be extirpated successfully. For an early diagnosis to be made it will, I think, be generally agreed that a careful chemical examination of the "gastric contents" is of the utmost importance. It is most essential that the method employed in this analysis should be of rigid scientific accuracy and also of clinical application. Approximate methods are of no value if fine distinctions are to be drawn from the results. The analysis must be of absolute accuracy if advances in the early diagnosis of disease are to be made.

I. "THE GASTRIC CONTENTS."—HOW OBTAINED.

The vomit may be used for the analysis if obtainable. Usually, however, it is better that the patient be given a "test meal" and the gastric contents be drawn off subsequently. It is, I think, advisable that the stomach should not be washed out before the test meal is given. The patient should, however, be kept on a restricted and light diet for a day or two previously so that any temporary dilatation of the stomach may be reduced. For the test meal various combinations have been recommended, some containing large quantities of proteid—e.g., eggs, meat, milk, &c. It will be generally agreed that the test meal should not by its complexity add to the difficulties of the analysis; on the other hand, it should be of such a nature that it will act as a stimulus to the gastric secretion.

It must be remembered that the amount of physiologically active hydrochloric acid present in the gastric contents is of the greatest importance and that this amount can only be determined by a quantitative estimation described below. There is no qualitative test which can be performed in a few minutes for hydrochloric acid when combined with organic bases (proteid, &c.). If these organic bases are not present in appreciable quantity in the test meal then a considerable amount of the hydrochloric acid may be in the free state and capable of demonstration in two or three minutes by Gunzberg's test. Now the presence of free hydrochloric acid is of very great value in diagnosis, since it is almost invariably absent in gastric carcinoma and almost always present in gastric and duodenal ulcer. Hence the test meal should be so chosen that when the gastric contents are drawn off some of the hydrochloric acid may, if possible, be uncombined and capable of immediate demonstration.

In order to decide on a suitable test meal I have performed several experiments. In the first place the delicacy of Gunzberg's test for free hydrochloric acid in aqueous solution was determined and it was found that a dilution of 1 in 100,000 was capable of clear demonstration. The same series of experiments was performed with the addition of fats and carbohydrates respectively, and it was found that these bodies do not sensibly interfere with the delicacy of the test. On the other hand, proteids—e.g., albumin, mucin, albumose, peptone, &c.—and also nitrogenous organic bases as creatine, creatinine, &c., have the property of combining with hydrochloric acid, so that when these bodies are present in considerable amount no free hydrochloric acid can be demonstrated by Gunzberg's test (or other tests for free hydrochloric acid). Thus it was found that a solution of hydrochloric acid of strength 1 in 500 (about the same strength as normal gastric juice) gave after the addition of excess of the above bodies no reaction for free hydrochloric acid. It is obvious, therefore, that the proteids present in eggs, meat, large quantities of milk, &c., will prevent the reaction for hydrochloric acid, though a normal amount may be excreted by the gastric glands. Beef-tea was made, using bovril and other meat extracts. It was found that this combines with a considerable amount of hydrochloric acid owing, not to the presence of proteids, but rather to the amount of nitrogenous organic bases present. Thus if hydrochloric acid is added to the beef-tea to the extent of 1 in 2000 it can just be demonstrated as free hydrochloric acid. Weaker strengths of hydrochloric acid gave no reaction for free hydrochloric acid owing to its complete combination with the organic bases present.

As a result of the above experiments and also from practical experience I have concluded that the following are examples of the most suitable test meals. A pint of weak tea (infused only two or three minutes) with the addition of not more than one ounce of milk and sugar if desired, or a pint of thin arrowroot made with water and about two ounces of milk, sugar being added to taste. Instead of the arrowroot, cornflour, thin gruel, or other carbohydrate food may be substituted. With the above liquid a round of thin buttered toast should be taken. The toast contains dextrin, which is a powerful stimulus to the gastric glands, and the solid particles, by acting as a mechanical stimulus to the pyloric sphincter, prevent the too rapid passage of the meal from the stomach to the intestines. The test meal should be given in the morning before any other food is taken and drawn off in an hour and a half.

In withdrawing the gastric contents it is important that there should be no dilution with water or the results of the analysis will be affected. A long soft tube should be passed into the stomach having an external piece longer than the portion inside the alimentary canal. The air should be withdrawn from the tube by inserting a syringe into the external end when syphon action will be started and the fluid will flow gently out on removal of the syringe. Of course, the stomach-pump might be used, but this is not usually necessary.

II. GENERAL EXAMINATION OF GASTRIC CONTENTS.

A portion of this is taken and allowed to settle, the centrifuge being used if necessary. A careful microscopic examination is made of the deposit. Starch granules, bacteria (sarcinæ, &c.), yeast cells, striped muscle fibres, and epithelial cells are commonly found, the latter often being especially numerous in cases of gastric carcinoma. The remainder of the gastric contents is examined as to its general appearance, acidity to litmus, smell, consistency, the presence of slimy mucus, &c. The substance is filtered and the filtrate is used for the subsequent examination.

The clear filtrate should be tested qualitatively for free hydrochloric acid and lactic acid (see below). For albumin (by the boiling test); mucin: by the precipitate with 5 per cent. acetic acid insoluble in moderate excess; albumose: the cooled filtrate after removal of mucin and albumin gives a white precipitate with salicyl sulphonic acid; peptone: the filtrate after addition of salicyl sulphonic acid in excess gives a white precipitate with Meyer's reagent. The biuret test may be conveniently used for detecting albumose and peptone after removal of albumin by boiling. Usually in the gastric contents much more peptone than albumose is found, often quite large amounts of the former. Dextrin and sugar should be tested for; of course, if milk has been taken lactose will be found, otherwise sugar would not be present save in diminished acidity of the gastric contents. Bile pigments are sometimes present in abnormal conditions owing possibly to reversed peristalsis. Blood should be tested for if the contents are brown in colour.

III. SPECIAL CHEMICAL EXAMINATION.

A. *Total acidity.*—A titration should be performed, 20 cubic centimetres of the filtered contents being taken, diluted with a little distilled water, and decinormal alkali run in from a burette. Phenol-phthalein and litmus are the indicators in common use for this estimation. They indicate the total free inorganic and organic acids, and also the hydrochloric acid combined with proteids and other organic bases. Phenol-phthalein is the more convenient since the titration may be done in the cold, litmus requiring a boiling temperature in order to remove CO_2. It must be remembered that phenol phthalein differs from litmus in one respect—viz, in the presence of alkaline carbonates, thus bicarbonates are neutral to phenol phthalein but alkaline to litmus Hence if carbonates are present a slightly higher result is obtained for the acidity with phenol phthalein than with litmus

Decinormal caustic soda is most commonly used as the alkali It should be as free from carbonate as possible It should be made up with pure caustic soda (obtained from alcoholic solution) and dissolved in air free water, the solution being kept so that it may not absorb CO_2 from the atmosphere Decinormal barium hydrate solution gives rather more accurate results than $\frac{N}{10}$ NaOH when phenol phthalein is used as indicator, since here no bicarbonates can be formed CO_2 should be removed from the filtered gastric contents before the titration is done by passing a current of pure air for two or three minutes through the warmed liquid The $\frac{N}{10}$ $Ba(OH)_2$ solution needs careful storage, since it is acted upon by atmospheric CO_2 and so weakened in strength owing to the formation of the neutral carbonate, the solution becoming milky Hence the solution should always be bright and clear before use The total acidity is usually expressed "acidity equivalent to so much hydrochloric acid"

B *Determination of the physiologically active hydrochloric acid* —The secretion of hydrochloric acid is one of the most important and characteristic features of the stomach and from the presence and amount of this substance in the gastric contents the most valuable aids to diagnosis are obtained Now in the gastric contents hydrochloric acid may be present in three forms —

(1) Free hydrochloric acid
(2) Combined hydrochloric acid (*a*) with proteids and nitrogenous organic bases } Physiologically active hydrochloric acid
(*b*) with inorganic bases—e g, NaCl

It is obvious that what is necessary to be known is the amount of physiologically active hydrochloric acid present Many misconceptions [illegible] "free" and "combined [illegible] is often thought that th [illegible] is of more importance than that of the combined acid This is not necessarily the case Hydrochloric acid which is combined with proteids and nitrogenous organic bases is hydrochloric acid which a short time before was free but which has already commenced its important duties in the process of digestion, it is therefore of quite equal importance with free hydrochloric acid The relative amounts of free and this combined hydrochloric acid depend solely on the quantity of proteids and organic bases present Of course the hydrochloric acid combined with inorganic bases need not be considered It is introduced into the stomach in the combined state as such—e g, sodium chloride It is hence of the utmost importance that the physiologically active hydrochloric acid should be determined by an absolutely accurate method and one which can be quickly and simply performed—i e, be of clinical application Also the hydrochloric acid should be "directly" estimated and not calculated indirectly from a titration of the acidity, since much greater accuracy results from a direct determination of the chlorides present

Few of the methods described give an accurate determination of the "*active hydrochloric acid*" and many are very complicated The method I have used for upwards of a year and which is a simple application of Volhard's determination of chlorides, is one [illegible] simple apparatus It [illegible] repeatedly demonstra[illegible] the process

Two equal volumes of the filtered gastric contents (20 cubic centimetres) are taken (*a*) One portion is diluted to about 60 cubic centimetres with distilled water, ten cubic centimetres of pure nitric acid, about five cubic centimetres of a solution of iron alum, and a measured excess (30 cubic centimetres) of decinormal silver nitrate solution are added $\frac{N}{10}$ ammonium sulphocyanide solution is run in from a burette until a permanent reddish brown tint just results The difference between the quantity of silver nitrate solution added and the ammonium sulphocyanide solution used gives the amount of total chlorides present as $\frac{N}{10}$ HCl An evaporating dish may be conveniently used for doing the titration (*Note* —If the quantity of gastric contents is limited 20 cubic centimetres may be used for the determination of total acidity with $\frac{N}{10}$ NaOH and phenol phthalein This liquid is then used for the estimation of the total chlorides exactly as described above)

(*b*) The other portion of the gastric contents is placed in a porcelain evaporating dish (four and a half inches in diameter) and evaporated to dryness on the water bath The solid residue is heated for about an hour on the water bath The dish is then placed on a piece of wire gauze and heated with a small Bunsen flame, the flame not coming in actual contact with the dish The heating is continued for about ten minutes until the residue is well charred The dish is cooled, about 60 cubic centimetres of water and the pure nitric acid are added, the contents being well stirred with a glass rod The titration is then performed exactly as described above (*a*) and the quantity of chlorides present given in terms of $\frac{N}{10}$ HCl The difference between the chlorides found in (*a*) and (*b*) expresses with great accuracy the amount of the physiologically active hydrochloric acid

Proof of accuracy of method —I have repeatedly tested this and invariably found the results extremely accurate Example A solution of hydrochloric acid of known strength was made up with a 1 per cent solution of commercial peptone The above method gave —

Amount of active hydrochloric acid found = 0 984 per cent
hydrochloric acid actually added = 0 989

Experimental error = 0 005 " "

Similar accuracy is obtained with smaller percentages of hydrochloric acid

Notes on the process —The effect of igniting the dried residue of the gastric contents is to drive off the free hydrochloric acid and also to decompose the organic bases which have combined with hydrochloric acid, thus causing the latter to be also volatilised The loss in chlorides, therefore, represents "the active hydrochloric acid" It is important that the dish be not heated over a free flame or else inorganic chlorides may be volatilised in small amount The presence of the black particles due to the charring does not in the least interfere with the accuracy of the titration, since the white precipitate of silver chloride and silver sulphocyanide forms an effectual contrast to this and the first appearance of a red brown tint in the titration can be immediately seen It is not necessary to filter off the charred particles as this introduces errors and makes the process unnecessarily complicated

Experiments relating to hydrochloric acid determination —If peptone or albumin is added in excess to hydrochloric acid of strength equivalent to that in gastric contents and the solution is evaporated to dryness and heated on the water bath for several hours there is no loss of hydrochloric acid Hence a temperature greater than that of the water bath—i e ignition—is necessary in order to drive off the hydrochloric acid combined with organic bases If hydrochloric acid of strength as in the preceding experiment is mixed with dextrose or dextrin, evaporated to dryness on water bath and the residue heated thereon for two hours there is only a partial loss (about one third) of the hydrochloric acid This proves that prolonged heating on the water bath of gastric contents may only partially drive off the free hydrochloric acid

Review of methods described for estimating hydrochloric acid in gastric contents —1 Sjoqvist described a method of estimating free hydrochloric acid by evaporation to dryness with $BaCO_3$ igniting and estimating the $BaCl_2$ formed The hydrochloric acid combined with proteid is not estimated

2 *Leo s method* —Total acidity is determined by titration with $\frac{N}{10}$ NaOH in presence of phenol phthalein, a correction being made for acid phosphates Here the hydrochloric acid is not directly estimated and organic acids cause errors

3 *Toepfer s method* —Titration with $\frac{N}{10}$ NaOH, using several indicators, for example —

(1) Titration using as indicator phenol phthalein gives total acidity
(2) " " alizarin gives free hydrochloric acid and organic acid
(3) " " dimethyl amido-azo-benzene gives free hydrochloric acid.

Here the hydrochloric acid is not directly estimated, also the indicators only give approximate results, they do not act quite as stated—e.g., [illegible] organic acid (see below).

4. Shufflebotham[1] in [illegible] paper called attention to the importance of "active" hydrochloric acid and rightly pointed out that free hydrochloric acid is much more often absent than present in the gastric contents of pathological cases. He gave a method of estimating the acids which is not of great accuracy: [illegible]) total acidity by titration with $\frac{N}{10}$ NaOH in presence of [illegible]enol-phthalein; and (*b*) organic acids estimated by extrac[illegible]n with ether. This latter process takes 24 hours and then [illegible] extraction may be incomplete to the extent of 10 per [illegible].

[illegible] Ham and MacLeod[2] gave a most interesting method of [illegible]mining free hydrochloric acid depending on the hydro[illegible] of cane sugar by the gastric contents. The estimation [illegible] 24 hours and requires a calculation by logarithms from [illegible]ewhat complicated formula. The polarimeter is used [illegible] determination. This method is useful for determining [illegible]ydrochloric acid, but it does not estimate the hydro[illegible] acid combined with proteid which is usually the more [illegible]ant *factor, since free hydrochloric acid is more often* [illegible] than present.

Dr. B. Dawson[3] gives a method of determining free [illegible]loric acid and organic acid. This method is not [illegible] since in the determination it is assumed that all [illegible] hydrochloric acid is driven off by heating on the [illegible]h, which I have shown above is not the case. Also [illegible] chloric acid combined with proteid is not estimated [illegible].

[illegible]idney Martin[4] gives a very accurate method of [illegible] the physiologically active hydrochloric acid, which [illegible]n principle to the method that I have described [illegible]ere are several details described in the process [illegible]ve found may be dispensed with, even greater [illegible]ulting from the *simpler method given above.*

[illegible]*ative tests for free hydrochloric acid.*—I have [illegible]rous experiments in order to determine the [illegible]ate method of detecting free hydrochloric [illegible] is no doubt that Gunzberg's test is the [illegible]rthy. *It is* most important, however, that [illegible]hould be freshly made up for each test. If [illegible]s made in bulk it loses its delicacy in a few [illegible]mes useless for accurate work. The best way [illegible]e test is to keep the phloroglucin and vanillin [illegible]les, to the corks of which are attached little [illegible]ill measure about four grains of the former [illegible]of the latter. These quantities are placed in [illegible]n evaporating dish, about one cubic centi[illegible] (pure methylated spirit does quite well) is [illegible] them, then about two cubic centimetres of [illegible]ic contents are added. The dish is heated [illegible] till its contents are nearly dry. A brilliant [illegible] indicates free hydrochloric acid; a yellow [illegible] I have found that 1 part in 100,000 of [illegible]an be clearly demonstrated by this test. [illegible]not give the test even if present in great [illegible]he extent of 1 per cent. or more. At the [illegible]ot interfere with the positive reaction if [illegible]id be present. *Carbohydrates and fats* do [illegible]ly with the delicacy of the test. The [illegible]ot indicate at all the presence of hydro[illegible]d with *proteid or organic* bases, only a [illegible]ng. Of course, if there is free hydro[illegible]as combined *hydrochloric acid then* a [illegible]ts, a red colour being formed.

[illegible]*benzene.*—An alcoholic solution of this [illegible]s a pink-red colour with free hydro[illegible] weak a solution as 1 in 100,000. I have [illegible]eristic colour is also given by lactic [illegible] as 1 in 10,000 and by acetic acid in [illegible] in 2000. Hence this reagent is not [illegible] since organic acids may give a re[illegible]ric acid when it is *not* present. On [illegible] found that the gastric contents gave [illegible] this reagent when subsequent in[illegible] free hydrochloric acid but organic [illegible] reagent does not react to hydro[illegible] proteid.

[illegible] *Tropeolin OO and Congo red.*—I have found that the reagents are unsatisfactory. They are less delicate than t[illegible] preceding and react to organic acids.

D. *Testing for organic acids.*—A qualitative test should [illegible] made, a weak solution of Uffelmann's reagent being added [illegible] the filtered gastric contents. The development of a distin[illegible] yellow colour indicates lactic acid. Acetic and butyric aci[illegible] do not produce the marked yellow colour given by lactic ac[illegible] *even in as weak a strength as 1 in 5000. The quantity* [illegible] organic acids is given with sufficient accuracy for practic[illegible] purposes by the difference between the total acidity (e[illegible]pressed as hydrochloric acid) and the active hydrochlor[illegible] acid as estimated by the method described above. Of cours[illegible] the organic acid may be directly estimated by ether[illegible] extraction (Shufflebotham method). I do not find th[illegible] usually necessary.

E. *Conclusions to be drawn from the results of an analysi[illegible]*—Careful analyses of the gastric contents have been made [illegible] upwards of 60 cases at St. Mary's Hospital during the la[illegible] four years. In most of these the diagnosis has been co[illegible]firmed by operation or post-mortem examination. Th[illegible] following are the conclusions which have been drawn fr[illegible] *the results of the above analyses.*

In gastric and duodenal ulcer the total acidity is high—e.g., from 0·2 to 0·3 per cent., or even more; this consis[illegible] almost entirely of "active hydrochloric acid." Free hydr[illegible]chloric acid is usually present. Organic acids are generall[illegible] absent. Peptone is absent or present in only small amount.

Temporary dyspepsia (e.g., vomiting from migraine).—He[illegible] the acidity is about normal—e.g., from 0·1 to 0·2 p[illegible] cent.—and it consists chiefly of "active hydrochloric acid[illegible] Free hydrochloric acid is present or absent according to th[illegible] nature of the food taken before the vomiting. Organic acid[illegible] may be present in small amount. Albumose and peptone a[illegible] often present in considerable amount.

Gastric carcinoma.—Here it has been found that th[illegible] nature of the gastric contents varies very much indeed wit[illegible] the position of the growth in the stomach. Thus, in involve[illegible]ment of *the cardiac portion of the stomach* the total acidit[illegible] is low, usually under 0·04 per cent.; free hydrochloric aci[illegible] is never present. "Active hydrochloric acid" is present i[illegible] *very small amount—e.g., about 0·02 per cent.*—or frequentl[illegible] absent. Organic acid is generally present, also traces o[illegible] mucin may be found, but little or no albumose or peptone[illegible] In involvement of *the pyloric portion of the stomach* the tota[illegible] acidity is sub-normal but still it may be considerable—e.g., from 0·05 to 0·1 per cent.; it is always much higher th[illegible] when the cardiac portion of the stomach is affected. Fre[illegible] hydrochloric acid is absent. Active hydrochloric acid ma[illegible] be present in fair amount but it scarcely ever exceeds 0·[illegible] per cent. Organic acids are present generally. Mucin an[illegible] albumin and often quite large amounts of peptone are found[illegible]

So great is the difference between the chemical composition of the gastric contents when the cardiac and pylori[illegible] portions are involved that the result of the analysis in a cas[illegible] of gastric carcinoma not only enables a diagnosis to be mad[illegible] but also gives a clear indication of the position of the growt[illegible] in the stomach.

[3] [illegible] System of Medicine.

SOME REMARKS ON ELECTROSTATIC TREATMENT.

BY J. CURTIS WEBB, M.A., M.B., B.C. CANTAB.

IN these days, when so much more attention is being bestowed on the scientific application of electricity to the treatment of disease than was formerly the case, I think there should be no excuse needed for bringing before the medical profession a modality as yet little used in England. In America, and also in France, an efficient electrostatic machine forms an important item in a medical man's equipment, but in this country many medical men are either entirely ignorant of its potentialities or are inclined to classify it rather as an appurtenance of the charlatan than as a potent means of relieving human suffering. Why this is so is difficult to explain. True, the [illegible] heavy: *for a thoroughly trustworthy mac*[illegible] far in excess of a d'Arsonval apparatus, [illegible] usually compared, but, on the other hand, [illegible] effect, and can do all that the d'Arsonval equipment can [illegible]ment.

an induction machine can give an amperage as high as a d'Arsonval, but it is as yet far from proved that any real good is effected by a high amperage. If we choose to utilise our Leyden jars we can get as high a frequency as the "highest frequenter" could desire, but is such high frequency always necessary or even to be desired? Let us be candid and acknowledge that we do not know exactly *how* these high potential currents act any more than we know exactly how potassium iodide acts. No one will deny the proved value of the latter; why then deny the possible value of the former? If the current from the static machine, one of low amperage and high potential, be as efficacious as that from the d'Arsonval apparatus, which is of high amperage, the possible risks from the latter are abolished. With a statical machine we have our potential under control and we have a multitude of modalities at our command—e.g., sparks of various kinds, brush, breeze, vacuum tubes, static induced, and last, and most important, the Morton wave current, with or without secondary interruptions. And further, and this is a point on which I cannot lay too great stress, there is the enormous difference as to whether we connect our patient to the positive or to the negative pole. I, too, was once an unbeliever, but I have over and over again proved to my own satisfaction that while the current from the + pole is essentially stimulating, that from the – pole is a sedative. Patients have for themselves detected the difference and while expressing themselves benefited by the one have been unable to bear the other.

It is important to realise from the start the characteristics of the static wave current, for that is the form to which all the other modalities are either accessory or subservient. It is essentially an oscillating one-pole current, with power to use either the + or – pole, as desired, of high or low potential, and of great or small frequency, under perfect control, painless during administration, and of such amperage as never to endanger the life of the patient, who, being insulated, is repeatedly charged and discharged synchronously with the interruptions at the spark gap, and owing to this insulation experiences the constitutional effects peculiar to currents from one pole of an induction machine, the local effects being produced under the surface and in the immediate neighbourhood of the electrode.

And here let me say at once that to get the best results, or, indeed, any real results, from a static machine it must be under the personal supervision of the medical man himself who has studied it. There are so many ways of applying the current, each one suited to certain diseases and certain temperaments, that it would be hopeless to send a patient to an institution not under the care of a medical expert for "static treatment." I believe there is only one recorded instance where a "bow drawn at a venture" sped its shaft with any efficacy, and "blazing into the brown" is notoriously uncertain, and the haphazard application of electrostatic currents can but end in disappointment for both patient and medical adviser and in loss of repute for a powerful weapon in our medical armamentarium.

The exact effects of these currents have been well classified by Snow, to whom we are indebted for much of our knowledge of this form of electric application. They may be divided into, A, local; and B, general.

A. *Local.*—1. Removal of the effects of stasis, with absorption of plasma and detritus, thereby lessening pain, and inducing reabsorption of fibrin, organic and inorganic salts—the results of defective metabolism. This is best brought about by the "wave current," which causes what I can most satisfactorily describe as a "histological massage." Every individual cell of the lymphatics and arterioles, under the direct sphere of the electrode, pulsates synchronously with the discharges at the primary spark gap, the rate of which is under absolute control, and this histological massage is entirely painless and should not cause contractions of the muscles as a whole, though this effect can be produced if the operator desires. 2. A rubefacient effect can be secured by the brush discharge. 3. If an ulcer or burn be under treatment in a short time the surface becomes coated with what may be likened to collodion, showing the coagulation of albumin, and any offensive odour is destroyed by the ozone liberated from the applied electric discharge.

B. *General.*—1. Equalisation of blood current and general lowering of arterial tension. In a patient of mine, aged 71 years, 20 minutes' treatment brought the blood pressure down from 180 to 150 millimetres of mercury, the pressure being taken at the radial artery with an Oliver's hæmodynamometer. 2. An effect on the nervous system, general or local, stimulating or sedative, according to the modality and to the current, whether + or –, employed.

The diseases where electrostatic currents find their main field of utility may be deduced from the above description. They are:—

1. All acute or chronic inflammations not due to microbic origin or to pressure of a growth, congestion of the liver with constipation, chronic inflamed joints, inflammation of nerves or of their sheaths—e.g., neuritis, neuralgias, [illegible] I may put in parenthesis that I [illegible] action in the treatment of these [illegible] her they be of rheumatic origin or not), ulcers, certain skin troubles, inflammatory glandular swellings, &c. Certain laryngeal affections form another class that is greatly benefited by the wave current. Chronic or subacute catarrh of the vocal cords, leading to hoarseness, or even aphonia, or to the loss or diminution of the power of singing, often yield readily to this modality. Singers who have "tired" their cords and feel that dragging sense of fatigue after singing, get their voices wonderfully toned up and strengthened by static electricity.

2. Owing to the power of the electrostatic current of contracting the unstriped muscular fibre of blood-vessels I have had excellent results in its use in cases of hæmorrhoids, especially in those conditions where the veins of the mucous membrane of the rectum are rather of a varicose character. Where there are large dilated clumps of veins operation may often be necessary but I would always be inclined to try electric treatment before resorting to a procedure that is often intensely painful and not infrequently has to be repeated. I have had more than one good result, too, in cases of anal fissure where both I and my patient have had every reason to be satisfied with the healing properties of the ozone evolved from the vacuum tubes.

3. In the cases of nerve diseases electrostatic treatment finds a wide field of usefulness. In early cases of locomotor, and in those affections due to inflammation of the cord or meninges, it has been found, though I regret I have not had an opportunity of personally proving this, that great good can be done, if not actually in effecting a cure, at least in arresting the progress of the malady. I have reason to know of its efficiency in cases of neuralgias, headaches, spasmodic dysmenorrhœa, functional neuroses, &c. In neurasthenia, with all its protean manifestations, I hold that we have no remedy to equal the one under consideration. In those cases, all too common in our present day of over-civilisation, complaining of constant backache, headache, continued sense of fatigue and inability, or in the case of "City" men who describe "loss of nerve," irritability, insomnia, loss of power of application or of decision, getting over-worried, in fact sufferers from "brain-fag," I know from my own results its enormous value. And if it were these classes of cases alone that were benefited by electrostatic treatment it would deserve the most serious consideration of every medical man to whom such patients come in the hope of getting relief. As a tonic it is unequalled, if by a tonic we understand that which either by soothing or stimulating restores to the normal a fellow creature whom objective disease or subjective symptoms have reduced to a condition of actual suffering or discomfort.

Bina gardens, S.W.

A NEW ELECTRO-CYSTOSCOPE.

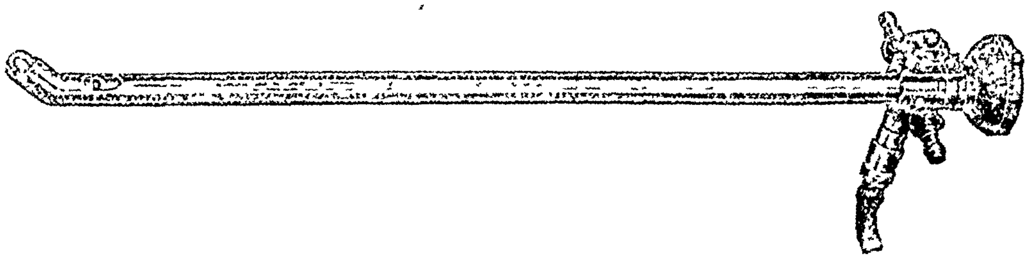
BY WILLIAM K. OTIS, M.D.,

PRO[illegible] YORK SCHOOL OF
THE NEW YORK
ST. MARK'S
ERMAN
[illegible]

OVER 25 years have passed since the invention of the electro-cystoscope by Nitze, and although many modifications of it have been presented during this period no one has succeeded in improving the ocular apparatus, so that the cystoscopes of to-day are no better than those manufactured by Hartwig or Leiter in 1887. The real optical difficulty which prevents an enlargement of the field or an increase in illumination in the Nitze instrument is due to the use of the prism as a means of diverting the light rays in order to obtain a rectangular view. From the opening of the window, or other face of the prism, in this instrument the rays of light must always travel a distance within the prism equal to its depth, so that if the angle of the lens be widened with a view to enlarge the field this increase will be unavoidably cut off by the sides of the prism. In other words, if you attempt to increase the size of the field by increasing the angle of the lens you simply succeed in seeing the sides of the prism. Moreover, it is necessary to have the prism proportionally so large that the telescope can have but a small lumen compared with the outside calibre of the instrument and thus a large amount of valuable light is lost.

After a series of experiments extending over several years in which I have been greatly assisted by Mr. Reinhold Wappler, I have succeeded in eliminating the prism by substituting in its place a hemispherical lens, the plane surface of which is silvered, a portion of the circumference filling and closing the window in the outer tube of the instrument. This procedure is, in reality, equivalent to the addition of plano-convex lenses to the superior and anterior faces of the prism.

FIG. 1.



The Otis electro-cystoscope. (Half actual size.)

This instrument resembles in general the cystoscope of Nitze but differs from it radically in several most important particulars. It consists of two separate parts, the external catheter, or sheath, carrying the illumination and the internal, or telescope, in which the entire optical apparatus is contained. The distal extremity of the external portion consists of a short beak (half an inch) set at an obtuse angle containing the electric lamp in its tip. This lamp is of peculiar construction and deserves special mention on account of its wonderful brilliancy and its freedom from heat. It is set so as to form the extreme end of the instrument; the light, unimpeded by any metal hood, illuminates the whole interior of the bladder. Its size is equal to the full external calibre of the instrument and it is set in a metal socket or tip which screws into place after the manner of the lamp in the Nitze model, which a long experience has convinced me is more convenient, when changing the lamp, than the method of Leiter, also used in the French instruments. One pole of the lamp is carried on the metal of the shaft itself, the other by a specially insulated wire which does not encroach upon the internal calibre of the shaft and permits the use of the telescope several sizes of the French scale larger than that of other instruments, thus allowing the passage of a greater amount of light with a corresponding brilliancy of field.

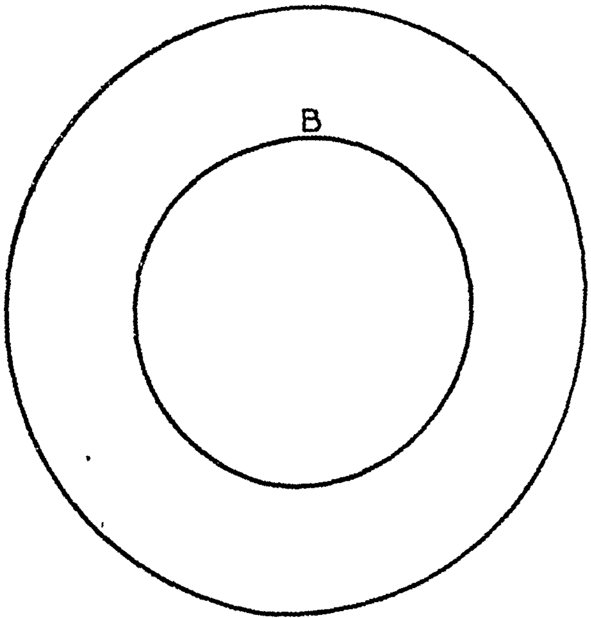
The shaft has a working distance of eight inches (i.e., from the centre of the window to the apex of the ocular funnel) and in the commercial instrument a calibre of 20 F. At the angle where the shaft joins the beak on its superior surface an oval window is cut through the metal to expose the lens of the telescope when in place. On the superior surface of the proximal end is a short screw, at right angles to the shaft, on top of which a small ball is fixed which indicates the position of the beak when the latter is in the bladder. A thumb-nut on this serves to clamp the telescope firmly in position. On the inferior surface of the proximal end of the shaft is a metal post with an insulated core which carries the electric terminals of the lamp and connects with the cords from the battery by a screw socket. A turn of this screw permits the lamp to be lit or extinguished at the will of the operator. For the sake of simplicity this post has been made immoveable and not working in a collar as in some instruments. Small stopcocks communicating with the internal calibre of the instrument have been placed just above the post for the introduction of air, for use when it is considered desirable to use air instead of fluid as an examining medium.

The telescope contains the entire ocular apparatus and fits easily in the sheath. On the superior surface of its distal end is a window cut in the form of the upper opening of a whistle, in which is set the hemispherical lens. The proximal end consists of a funnel eye-piece with a moveable collar at its apex to which is fastened a small flat fork or crotch, the prongs of which pass on either side of the screw on the shaft and serve to clamp the telescope firmly to the sheath with the thumb-nut, at the same time allowing the telescope to turn on its own axis. A partial rotation of the telescope in this collar causes the lens at the end to slide from the window of the sheath, the opening then being filled by the back of the telescope, the lens facing the back of the sheath. In this way the cystoscope is introduced into the bladder, the lens being entirely protected from any contact with blood, pus, or lubricant, which is most desirable when using a fluid medium and absolutely essential when air is employed.

After the instrument is well in the bladder the lens is brought into the window by rotating the telescope, a small knob on the ocular funnel indicating its correct position. Should the fluid in the bladder become clouded at any time on account of bleeding or the presence of pus it is only necessary to remove the telescope; the sheath, acting as a large catheter, permits the rapid withdrawal of the fluid contents of the bladder, which can be refilled, the telescope replaced, and the examination continued with but little loss of time and without removing the instrument, a much more effective method than that employed in the so-called irrigation cystoscopes all of which are necessarily feeble and ineffective.

To describe this instrument in detail without becoming prolix is difficult and as it is the practical advantages which interest most surgeons I shall enumerate these as they occur in this cystoscope. A field having an area four times as large as that of any other rectangular cystoscope, so that it is practically impossible to overlook a pathological condition in the bladder which might easily escape the smaller field of

FIG. 2.



A, Field of Otis cystoscope, distance of four centimetres.
B, Field of Nitze cystoscope, same distance.

the instruments now in use. Not only is this accomplished without loss of definition, but the field of this new instrument is rendered clearer and brighter on account of the more powerful illumination of its lamp, the greater calibre of the telescopic tube, and the arrangement of the lens system. After an extended practical experience and a thorough familiarity with the cystoscopes of European manufacture I do not hesitate to say that the field in none of them compares in distinctness and brilliancy with the picture as seen through this cystoscope covering a four times greater area. Nor have they the penetrative power or the ability to see distinctly at a distance from the object, as no matter how much the bladder may be distended a clear image may be obtained from any part of its interior with this instrument.

The outer circle (A) represents the field of the author's instrument at a distance of four centimetres from a flat surface and the inner circle (B) represents the field of the Nitze instrument at the same distance. Without referring to the optical formulæ by means of which these comparative areas have been arrived at the sizes of the fields in the illustration were obtained by the common-place method of clamping the instruments at a given distance from a highly-illuminated sheet of paper, and beginning at the extreme upper edge of the field, as seen through the telescope, drawing a line through the centre from where the point of a pen first came into view to a point just opposite in the circle where the pen-point disappeared, the resulting line being used as the diameter of a circle representing the field of the instrument.

The arrangement and quality of the lamp and the large calibre of the telescope rendered possible by the special device for insulating the second pole of the lamp and the elimination of the prism give an illumination of field better than in other cystoscopes, on the principle that more light will pass through a large tube than a small one. The lamp, the filament of which is prepared by a secret process necessitating a very high vacuum, has such a low amperage that it emits almost no heat, making it impossible to scorch or, as has happened, seriously burn the bladder wall. This cool, powerful lamp, together with the protection of the lens from being smeared during introduction, permits the use of air as the examining medium should this be considered advisable. The short beak and absence of the flat top and sharp angular sides of the prism render it easy of introduction and less liable to cause bleeding. Should the medium in the bladder become clouded it may easily and rapidly be withdrawn and replaced without removing the instrument.

New York.

A CASE OF PYREXIA FOLLOWING CHILDBIRTH TREATED WITH ANTISTREPTOCOCCIC SERUM.

BY P. H. WARD, M.R.C.S. ENG., L.R.C.P. LOND.

HAVING read with considerable interest Mr. A. G. R. Foulerton's and Dr. Victor Bonney's article in THE LANCET[1] on puerperal infections I think it might serve a useful purpose to put the following case on record.

The patient was an elderly multipara. Her two youngest children were aged five and 17 years respectively. There was a history of several miscarriages and at previous confinements trouble with the placenta which on one or two occasions had been taken away in small pieces. The last confinement five years previously had been easy and normal. I was called at 9.30 A.M. on April 2nd and was informed that the waters had broken at 11.30 P.M. the previous night. The patient was not in labour. Abdominal palpation to ascertain the position of the child proved unsuccessful on account of considerable tenderness especially over the suprapubic region and to the left of the middle line low down. On the 3rd, at 3.30 A.M., I was again called. The patient had been in labour since 1.30 A.M., the labour having commenced 24 hours after rupture of the membranes. The os was of the size of a florin and the head presenting in the first position. The pains were weak with long intervals and disappeared altogether when the patient lay down. The os dilated very slowly but once dilated labour proceeded rapidly and a very large child (weighing 11 pounds) was born at 9.30 A.M. Considerable hæmorrhage occurred after the birth of the child. The placenta was delivered by external compression. The membranes seemed rather firmly attached and had to be twisted many times before sufficient traction could be made on them to remove them without tearing. Examination of the placenta revealed that the membranes had ruptured high up near their placental attachment. They were very friable. The placenta looked unhealthy, also being extremely friable. After delivery of the placenta the patient became faint with a weak and irregular pulse. Extractum ergotæ liquidum (one drachm) was administered. An urgent message made it compulsory for me to leave though the patient's condition was somewhat unsatisfactory. I was recalled shortly after as the patient was flooding. This was controlled by external compression of the uterus. She was ordered a mixture containing extractum ergotæ liquidum every four hours. The same evening the temperature was normal. The patient in all lost three or four pints of blood.

On April 4th at the morning visit the patient was feeling well; the temperature and pulse were normal. At the evening visit she complained of feeling hot and was perspiring freely. She had shivered during the afternoon. Her temperature was 102° F. and the pulse-rate was 120, weak, and irregular. A vaginal douche was ordered. She had a second rigor the same evening. On the 5th, at the morning visit the temperature was 102·8° and the pulse was 120. The patient was given calomel (six grains) to be followed in four hours by magnesiæ sulphas (two drachms), also tinctura ferri perchloridi (half a drachm) every two hours. The vagina was also douched. At the evening visit (6.30 P.M.) the temperature was 103°; the pulse was over 120, very weak, and irregular. The bowels had acted freely. An intra-uterine douche of hydrargyri perchloridum, 1 in 2000, followed by 1 in 4000, was given at 8 P.M. When the temperature had risen to 104° ten cubic centimetres of polyvalent antistreptococcic serum (B. W. and Co.) were injected. On the 6th the patient had slept fairly well. The bowels had acted eight times since the administration of the calomel. The temperature was 102·8°; the pulse was 120, stronger, and more regular. The discharge was scanty. The uterus reached half way to the umbilicus and was tender over precisely the same place where tenderness had been most marked before delivery. The uterus was washed out with hydrargyri perchloridum, 1 in 4000, and I injected ten cubic centimetres of polyvalent antistreptococcic serum. Unfortunately I had no more of the serum left after this injection. On the same evening Mr. W. Watkins, whose practice I had just taken over, kindly saw the patient with me. She refused chloroform, so Mr. Watkins explored the uterus with his finger without an anæsthetic. He removed a shred of membrane and two pieces of placenta of about the size of a hazel-nut from the left cornu of the uterus. These pieces of placenta were very firmly adherent. They were distinctly foul smelling. The uterus was douched with hydrargyri perchloridum, 1 in 2000, followed by 1 in 4000. An iodoform pessary was left in the vagina. The temperature was 102° and the pulse was 120. On the 7th, at the morning visit the temperature was 102° and the pulse was 112. The patient was suffering from diarrhœa. The discharge was scanty and hardly coloured. The milk was becoming scanty. At the evening visit the temperature was 102·8° and the pulse was 112. An intra-uterine douche of lysol was administered both in the morning and evening. On the 8th, at the morning visit the temperature was 104°. The diarrhœa was better, bismuth and liquor opii sedativus having controlled it. The tinctura ferri perchloridi was omitted. The patient complained of pain over the uterus. The discharge was not coloured and scanty and there was almost absolute suppression of milk. She was intensely anæmic. The tongue was furred but moist. The uterus was washed out with lysol. At the evening visit the temperature was 102° and the pulse was 112. The uterus was again washed out. A fresh supply of antistreptococcic serum having been obtained ten cubic centimetres were injected. The uterus was washed out with lysol. On the 9th, at the morning visit (8 A.M.) the pulse was 100 but weak and thready; the temperature was 102°. The patient complained of diarrhœa. There was no discharge. Pain was felt in the pubic region on coughing. She had had a restless night and complained of weakness in the head. She said she wanted to think but could not. The anæmia was more marked. At 9.30 A.M. the temperature was 103°. Ten cubic centimetres of antistreptococcic serum were injected. The uterus was washed out with perchloride, 1 in 2000, *followed by 1 in 4000. In the evening the temperature* was 103°. On the 10th, at 8 A.M. the pulse was 92 and the temperature was 101°. At 10 A.M. the pulse was 92 and the temperature was 99·8°. A lysol douche was given. In the evening the temperature was 102·8° and the pulse was 92. A lysol douche was again administered. A powder containing pulvis ipecacuanhæ compositus (ten grains) and quininæ sulphas (ten grains) was given at 9 P.M. On the 11th, profuse sweating had taken place during the night; the temperature was 97·8° and the pulse was 88. The same evening the temperature was 99°. After this the patient slowly recovered. The [illegible] but the discharge only became very [illegible]. A week later she had a slight shivering attack and the temperature ran up to 101° but it came down the same day and remained normal. During convalescence the temperature was constantly subnormal in the morning.

[1] An Investigation into the Causation of Puerperal Infections, THE LANCET, April 8th (p. 915) and 15th (p. 992), 1905.

Remarks.—There was apparently some morbid intra-uterine condition before the confinement, for tenderness was most marked. Also during labour the patient was not able to aid the expulsion of the child by bearing down. She explained afterwards that when she tried to bear down it was "as if something was tearing inside her womb." Within 36 hours of delivery she had two rigors and a temperature of 102° with a weak irregular pulse of 120. Every symptom of severe septicæmia followed, suppression of lochia and mild diarrhœa being most marked. The most striking feature of the case was the patient's cheerful disposition. She made light of her illness, so much so that each morning her husband cheerfully informed me there was a great improvement and hardly realised the gravity of the case.

About 48 hours from onset of the pyrexia two very small pieces of stinking placenta were removed from the uterus. The temperature, however, remained raised for three days longer. Was this pyrexia due to toxæmia already resulting from the retained placenta or was it due to an additional streptococcic or other infection? The first two injections of antistreptococcic serum apparently had little effect. On obtaining a fresh supply of serum two further injections were made, the temperature falling to 99° within 24 hours of giving the last injection. I think at least this warrants a further trial of the serum treatment if nothing else. No ill-effects were observed from any of the four injections, there being neither pain nor the slightest inflammation at the site of injection. Within the 12 hours preceding attending on this case I had opened a foul axillary abscess and also a whitlow. After returning from these two cases I had on each occasion carefully sterilised my hands, scrubbing them with lysol, hydrargyri perchloridum 1 in 1000, and finally immersing them in carbolic 1 in 20. Also bearing in mind that I had opened these abscesses, at the confinement I was more than usually careful, sterilising my hand before every examination and making as few as possible. I, however, wore the same suit of clothes.

Murraysburg, Cape Colony.

DISLOCATION OF THE CARPAL SCAPHOID.

BY ANDREW FULLERTON, B.CH. R.U.I., F.R.C.S. IREL.,
HONORARY ASSISTANT SURGEON, ROYAL VICTORIA HOSPITAL,
BELFAST, AND THE BELFAST HOSPITAL FOR SICK
CHILDREN; EXAMINER IN SURGERY, ROYAL
COLLEGE OF SURGEONS IN IRELAND.

DISLOCATIONS of the carpal bones are exceedingly rare. Deaver[1] says that "the separate carpal bones are rarely if ever dislocated." Makins[2] mentions that "the scaphoid and semilunar have been seen to be dislocated, usually in compound injuries." Erichsen[3] describes dislocations of the os magnum, pisiform, and semilunar. Cheyne and Burghard[4] think that "dislocation of one carpal bone from another, although sometimes met with, is of such extreme rarity that the accident does not require any special mention." Hamilton[5] says: "I have found no account of an example of simple dislocation of single carpal bones except in the case of the os magnum, pisiform, and lunare." Gant mentions dislocations of the semilunar, cuneiform, pisiform os magnum, and unciform as having occurred but does no appear to have met with or heard of a case of dislocation o the scaphoid. Haughton and Holt[7] discuss the frequency o fracture and dislocation of the proximal row of carpal bon with displacement of fragments but dislocation of th scaphoid pure and simple is not mentioned.

The following case came under my notice at the Roya Victoria Hospital, Belfast, during 1904. A man, aged 5 years, about three years ago slipped on the pavement owin to the frost. He put his left hand behind him to sav himself and fell heavily on the front of his wrist. On risin he noticed a small lump on the back of his hand. He wa treated at hospital for a short time and went back to work the nature of his injury not having probably been recognised Ever since his wrist [illegible]. About three week before his recent attendance he [illegible] the back of hi hand and applied at the Royal Victoria Hospital for furthe treatment. On [illegible] projection, irregula in shape, could [illegible] of the left wrist, th middle being about three-quarters of an inch from the radi border and just below the level of the styloid process o the radius. The carpus was stiff and painful and the bone appeared to be welded together. Flexion and extension wer very limited. Several skiagrams were taken and reveale an undue sharpness of the styloid process of the radius and want of distinctness and separation of the bones in the centr of the carpus. It would appear from the skiagrams that th os magnum had become fused or closely joined to the neighbouring carpal bones.

Operation.—A longitudinal incision was made on th dorsum over the projection. The scaphoid was found displaced backwards and [illegible] tubercle presente on the back of the carpus. The bone was removed and tw small fragments, flat and irregular in shape, about one-thir of an inch in length and rather less in breadth, were foun lying loose in the cavity left. It could not be determine whether these were originally chipped off from the radius o one of the carpal bones. He probably fell on the prominenc of the scaphoid in front and so displaced the bone backward taking off a small portion of the radius (hence the sharpne of the styloid process) and probably fracturing one or mor of the other carpal bones. The callus thrown out woul probably account for the welding seen in the skiagram. Th tip of the styloid process of the ulna had evidently bee broken off.

The removed scaphoid presents the following appearance The superior surface is devoid of articular cartilage, smooth and eburnated over a triangular area corresponding to abou half the total extent. This area is confined to the anterio portion of the articular surface for the radius. The posterio portion is rough and non-articular. The inferior surfac (that for articulation with the trapezium and trapezoid) i devoid of cartilage and eburnated at its anterior extremity The posterior portion is rough and non-articular. The dorsa surface is normal. The anterior surface appears to have ha a small fragment broken off (perhaps one of the loose fragments above referred to). The external surface was slightl damaged during removal. The internal surface for articulation with the semilunar above and the os magnum below, ha become rough, owing, no doubt, to want of apposition of th normal articulating bones. It would therefore appear tha the scaphoid articulated at the two eburnated surfaces onl and these are diametrically opposite to each other.

Healing of the wound took place by first intention bu owing no doubt to injuries to other carpal bones the movements at the wrist joint and carpus are limited.

Belfast.

A CASE OF POISONING BY FLUID AMMONIA USED FOR DOMESTIC PURPOSES.

BY H. SAVORY, M.A., M.B., B.C. CANTAB.,
ASSISTANT PHYSICIAN TO THE BEDFORD COUNTY HOSPITAL.

A LITTLE four-year old patient of mine has had a narro escape from death by misadventure. She was playing wit a small doll's tumbler and asked her nurse to give her a dose of fluid magnesia in it. The nurse went to the cupboard and poured out about 40 drops of Scrubb's cloudy ammonia by mistake for fluid magnesia and gave it to the child, who put it at once into her mouth. This caused a severe spasm of the glottis and though some burnt the roof of the mouth and tonsils, in all probability very little was actually swallowed. The child was picked up partly unconscious and brought downstairs to me, as I happened to be in the house at the time. She had uttered no sound and seemed incapable of expectorating. I inverted her and opened the mouth and washed out what I could; she could not swallow but she had just had a large meal and the induction of vomiting removed what little ammonia remained in the mouth and gullet. It was impossible to administer any antidotes, even white of egg caused great pain when introduced into the mouth. Very soon her respiration became impeded with all the signs of œdema of the glottis. The intercostal and epigastric recession became so marked that my colleague (Mr. Gifford Nash) and I decided to prepare the instruments necessary for tracheotomy and I waited all night expecting at any moment to have to perform the operation but towards morning the laryngeal symptoms began to abate. Loud rhonchi and râles were audible all over the chest and the temperature rose at the end of 12 hours to 104° F. The child remained in a dazed, torpid condition; we could not hear what she attempted to say and it was doubtful if she heard when we spoke. She could not take food; white sloughs formed on the palate, fauces, and buccal mucous membrane, and the tongue looked red and raw. Gradually these conditions improved and at the end of a fortnight she had practically recovered but the voice remained weak, uncertain, and raucous.

I am placing this case on record as it seems to me that the danger to the public from fluid ammonia is not an inconsiderable one. There are deaths recorded from either smelling or taking this powerful poison but as it is not included amongst the poisons scheduled in the Pharmacy Act there is no obligation on the part of the seller to dispense it in a poison bottle or to label it "Poison" or "Not to be taken" or "Not to be smelled." In the short time that has elapsed since the misadventure to my patient I have heard of several similar accidents. Another little patient of mine picked up the ammonia bottle in the bathroom, sniffed at it, and dropped the bottle which broke. Fortunately the crash of breaking glass was heard by an elder sister who had the sense to pick the child up and carry her out into the open air. The child was very ill but recovered.

Dr. J. O. Harvey of Bexhill-on-Sea writes to me: "When surgeon to one of the Union Co. South African Mail boats a child of about three years of age was playing with what appeared to be an empty Scrubb's ammonia bottle, in the absence of its nurse, and I well remember the alarming consequences that ensued. Not only was it doubtful whether the child would live but whether the windpipe should be opened, the child remaining in a precarious condition for 36 hours. The amount in the bottle was quite small as it was regarded as an empty one. The whole thing made such an impression on me that I am in the habit when seeing Scrubb's ammonia in the nursery of regarding it as a dangerous thing to be there. It is a preparation largely used in households and by nurses and I have thought that the risks to children are not sufficiently known."

I have not searched the literature of this subject but I have little doubt that many other instances could be collected. I pointed out to the manufacturers of the ammonia fluid the desirability of some warning to the public that their preparation is poisonous but they replied that "the occurrence seems to them to emphasise the gross carelessness of the giver of the dose rather than any omission from their label." I notice, however, that the public are warned against injurious imitations. This accident, or a similar one, might happen in any household or nursery to which fluid ammonia gains access (in this case the ammonia reached the house as an advertisement sample and gained admission to the nursery unknown to the head of the house), for though nurses, and this one in particular, are the devoted slaves of their charges, there are always times of mental aberration and mistake. A fluted unbreakable bottle or a poison label would, in my opinion, tend to minimise these mistakes and secure the greater safety of the public.[1]

Bedford.

SLIGHT ERRORS OF REFRACTION AND THEIR INFLUENCE ON THE NERVOUS SYSTEM.[1]

BY C. ERNEST PRONGER, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO THE HARROGATE INFIRMARY.

TWO years ago I read at a meeting of this society a paper on the influence of slight errors of refraction as a starting point of many functional nerve troubles quite apart from any impairment of vision or local discomfort to suggest eye trouble. I mentioned some of the commoner remote effects of eye strain such as migraine and the various forms of headache, insomnia, vertigo, depression, irritability, choreic movements of facial muscles, and various troubles usually treated as disorders of the liver or stomach. Having referred briefly to epilepsy, *petit mal*, chorea, and hysteria, the question was submitted for your observation and consideration as to whether the real starting point of those varied symptoms to which the name neurasthenia has been given might not be slight error of refraction; that the soil being prepared as it were by its insidious harmful effects, the supervention of shock or any one or more of the long list of causes of neurasthenia which have been suggested might not bring about the crisis or breakdown which at first sight would be looked upon as the beginning of the condition of neurasthenia.

Your reception of my paper was most gratifying to me and it has been still more gratifying to note that the large majority of you have put to a practical test the propositions submitted to you. Some, of course, were sceptical and a few scoffed and it was remarked that "Pronger was going to cure everything with spectacles," and in reply I ventured to predict that we should in time hear much more of this subject. My paper, read and printed in March, 1903, was followed in September by a long article in the *British Medical Journal* on a book, "Biographic Clinics," brought out by Gould of Philadelphia, and it was very pleasing to me to find that many of the main points advocated in that book were identically the same as in my own paper. About 12 months later an article by Snell of Sheffield on Eyestrain as a Cause of Headache and other Neuroses appeared in THE LANCET[2] in which he quoted freely from Gould's book and corroborated it in detail.

From the dates given in some of the cases in my paper it will be seen that this special subject has engaged my careful attention for more than ten years (my first paper on this subject was in 1895) and Gould, in a letter recently received from him, tells me that he has long been urging this subject upon the profession. Now, when two men working upon the same lines and quite independently for some years arrive at practically the same results it would seem probable that their conclusions would be fairly accurate. More especially should it be the case in regard to these slight errors of refraction, seeing that many of the remote effects of the higher degrees have been recognised and recorded.

In continuation of my paper of two years ago I want to say something about neurasthenia, if I may venture to discuss a subject which has hitherto been generally looked upon as quite outside my department and belonging almost exclusively to the province of medicine. Now if we consider for a moment the many suggested causes of neurasthenia, and let us take for example a very common one, worry, we are at once struck by the fact that out of large numbers subject to this influence only one here and there actually breaks down under it. Is it that the worries and anxieties of these few are so much greater than those of the others, or is it that the nervous system is less stable, that there is some predisposing cause which renders it less able to resist the tax put upon it? We might go further, for in many cases of neurasthenia one of the earliest symptoms observed is a disposition to worry about the merest trifles and in such cases if really great worries or anxieties were to crop up a

---

[1] According to our analysis the fluid ammonia contains about 120 times its volume of ammonia gas. We drew attention to the danger of toilet ammonia in lay hands in an annotation in THE LANCET of

that "a warning should be
ning ammonia for domestic
n large quantities and that
d to prevent the wholesale

[1] A paper read before the Harrogate Medical Society on March 30th, 1905.

[2] THE LANCET, April 30th, 1904, p. 1181.

where previously chaos reigned. It is impossible, of course, to say or conceive what might have been, but my own personal conviction is that I should have been less of an ass if my eyes had not troubled me so persistently. My internal and secret profanity must have at times satiated the devil himself, assuming such a personage to still exist. I sincerely hope that this happier frame of mind will become chronic and that you may long be spared to alleviate the suffering which can only be understood by those who have had to endure it for years as I have done. I have endeavoured to represent to you as nearly as possible my actual feeling on this subject and trust you will excuse my departure from conventional expressions in my effort to truthfully convey my ideas."

One meets with constant variety in the cases sent to one as neurasthenic and it is sometimes very difficult to tell how much is due to functional disturbance and whether there may not be some organic lesion present.

CASE 6.—A patient was sent to me in May of last year in whom no organic lesion had been detected, although she had been seen by several medical men and yet that patient died in the following November and the necropsy revealed chronic Bright's disease. This patient derived very great benefit from the use of glasses in the relief of her neurasthenic symptoms and the case is instructive in that it shows how necessary it is to bear in mind the possibility of refractive error being present as a complication in cases of organic disease. Had the Bright's disease been recognised her neurasthenic symptoms would no doubt have been attributed to that and the patient would not have been sent to me.

Especially would I suggest this point to you in connexion with gout, for when once that word has been used there is a great disposition both on the part of medical men and patients to attribute all symptoms to that special cause, and but for this complication being overlooked many cases of headache, insomnia, &c., might be speedily relieved. Perhaps it more frequently happens that serious brain or other lesions are supposed to exist in which the results show that the troubles are entirely functional. The following is an illustration.

CASE 7.—The patient, a man, aged 44 years, had suffered for some years from nervousness, dizziness, and headaches and for the last six months had been obliged to give up his occupation. From the severity of his symptoms generally his medical attendant wrote that he feared some serious brain trouble. The medical man who saw the case here asked me to examine him and I prescribed glasses for constant use. The medical attendant at home was at first somewhat annoyed as he had already sent the patient to an ophthalmic surgeon who had found slight astigmatism but had considered it so slight as to be of no special importance. The patient got rapidly better, returned to his occupation, and has since been to Harrogate for a holiday but feels that [illegible] This case shows how [illegible] of refraction and how [illegible]

CASES 8, 9, AND 10.—It is always interesting to watch the effects of treatment in cases in which the conditions are similar and in that respect the three following instances are of use. In the spring of 1903 three patients came under observation, all married, all about the same age, in similar conditions of life—one being a solicitor, one a medical man, and one a manufacturer—and having similar symptoms: headaches, irritability, depression and feeling unfit to continue the ordinary duties of daily life. They had all tried the usual remedies advocated in these cases, special attention having been paid to the functions of the liver. In spite of treatment they had all arrived at that stage in which something must be done, as they could not go on as they were. In all three cases a sea voyage had been prescribed. In all three cases the vision was quite good and there was no complaint of any kind directly connected with the eyes. The medical man came to see me and I ordered glasses for slight astigmatism to be worn constantly and he started for the voyage. The solicitor also went by the same ship but knew nothing of his fellow passenger and he did not consult me before leaving. The manufacturer after hearing my opinion of his case decided not to take the voyage but returned to his duties. The medical man tells me that the long rest and change of the voyage undoubtedly did him a great deal of good and he also noticed that he could read in the train without headache since wearing the glasses which he could not do previously. I, too, have observed that although the glasses are not in any way a necessity from a visual point of view, that he is now never seen without them, in fact, on three occasions he tells me that he has got into bed with them on. The manufacturer has taken no voyage but steadily improved in health and in six weeks reported himself as much better. The improvement continued and I saw him recently in his usual good health and enjoying life again as of old. He was rather indignant at being sent to me as he had been told previously that his eyes were normal, but he tells me he wears his glasses constantly and has done so ever since I first saw him. The solicitor returned from the voyage greatly disappointed as he was little if any better. A few weeks later, being as bad as ever, he consulted me and I prescribed glasses for constant use. In a letter received six months later his wife writes: "My husband is now very well indeed," the "very well" being underlined.

CASE 11.—It is my lot frequently to see instances in which the whole career of an individual has been blighted and changed as the result of a cause which might have been easily remedied had it been detected and its importance recognised. This nearly happened to the writer of the following letter who was considering the question of giving up his post when he was advised to consult me. This advice was a surprise to him as he had always attributed his symptoms to digestive disturbances and had had no discomfort in the eyes and was not conscious of any defect. He wrote me four months after his visit as follows: "I must tell you of the great benefit I have received from the constant use of the glasses you prescribed for me on July 1st last (1903). I had suffered from headaches for many years, the pain being chiefly frontal and at times so acute that the whole of my head felt as though it had been burnt. About three years ago I was subjected to a very peculiar attack; a sudden dizziness overtook me when just awaking from sleep and I fell into an unconscious condition which lasted for about 15 minutes. On recovering I was left with one of those violent headaches. These attacks I suffered from repeatedly and when up and about it required a very great effort to prevent oneself from becoming unconscious. I saw a London specialist who advised the use of bromides but with no definite result. Towards the end of June last Dr. —— advised me to consult you and I have worn the glasses ordered ever since. About ten days after this I had another of those attacks, perhaps the most violent I have had, this occurring early in the afternoon. Previous to this attack I had occasionally discarded my glasses but since then I am never without them. Four months have now elapsed and so far as these attacks are concerned there seems no probability of their return. Before my visit to you lapses of memory were almost a daily occurrence, now they are practically unknown and when in evidence are but momentary. The periods of dizziness have quite disappeared. I feel better in health, my brain is clearer, the headaches have never returned since I wore the glasses, and the state of depression into which I was sinking has entirely passed away."

Were I to assert that error of refraction is responsible for a large proportion of the suicides occurring daily and that it is a potent factor as a cause of insanity that assertion would probably be held up to ridicule and dismissed as absurd. Many things appear at first sight improbable but on reflection much less so and I will ask you to reflect for a few minutes on this subject. When you have seen as I have done, in a very large number of cases the effect of uncorrected errors of refraction on the nervous system you will be struck by the great frequency of the occurrence of such symptoms as insomnia, great irritability, extreme depression, impaired memory, difficulty of concentration of thought, lack of self confidence, apprehension, weariness and exhaustion, and a general want of stability of the nervous system. I have tried to illustrate error of refraction as the cause and the correction of it the cure for these troubles. How often the patients have told me that they have been on the verge of suicide and have used the expression that they were afraid they were going out of their minds. It is quite conceivable that suicide would be more likely to occur in those who had been for a long time enduring the mental torture which results from the conditions I have enumerated and which has rendered life a burden. I will read one or two extracts from actual reports of suicide: "The deceased had been very low spirited and had been under medical treatment for six months; she complained of pains in the head." Another case: "The deceased had been afflicted with nervous debility about four years." Again: "The deceased had suffered latterly from insomnia and had been much depressed." Again: "The deceased had suffered from influenza, later insomnia, and had been taking narcotics to induce sleep."

CASE 12.—If alongside these extracts you read some of the cases I have already quoted or the following letter it certainly provides suggestive material for consideration. The writer says: "I must tell you how grateful I am for what you have done for me. I should have written long ago but wished to give the glasses a thorough test and to see if the attacks of terrible depression returned which I have suffered from previous to seeing you. I am glad now to tell you I find the glasses a great comfort and have never once had a return of these particular attacks of depression which had hitherto made life a misery to me." Many of you will be able to recall instances of sufferers such as I have described flying to narcotics or alcohol for temporary relief from their distress and no doubt this leads to much of the secret drinking which prevails to so great an extent. In view of the large number of suicides attributed to alcoholic excess ought we not to look upon intemperance as a disease and always try to find out the circumstances attendant upon its commencement as to whether or not it might be due to a remediable cause? We should often be able to trace it to conditions of suffering such as I have described and on examining the patient the presence or absence of error of refraction would be a most important point.

CASE 13.—Errors of refraction are largely on the increase and for two reasons, first, as a result of the great demands made upon very young children by the educational system of the present day, and, secondly, from the fact that they are hereditary. Insanity is also largely on the increase, not only numerically but proportionately. May there not be a connecting link between these two facts? Much that I have said in regard to suicide might also be applied to the question of insanity. To those of you who have had much experience of cases similar to those I have represented it would not, I think, require a great stretch of the imagination to suppose that some of them might lose their mental balance and become insane or gradually drift into a condition of melancholia. Insanity is sometimes attributed to shock, but it would be an alarming thought to feel that any one of us if exposed to a severe shock might suddenly become insane. We could more readily understand such an effect being produced in one who has been a long sufferer from neurasthenia, and this reminds me of a case sent to me recently for neurasthenia. The medical attendant told me that she had on two occasions been out of her mind, the cause being attributed to shock at the loss of her sister who had suddenly disappeared when on board ship and had not been seen since. This patient had for a long time suffered from neurasthenic symptoms and had always been of a highly strung nervous temperament. She had slight astigmatism in both eyes but of different degree. She had previously been sent to two eminent ophthalmic surgeons but they had apparently not attached sufficient importance to the refractive error to insist upon its constant correction.

Again, what a very important position is always assigned to alcohol in the list of causes of insanity. If alcohol by itself were the cause of insanity we should expect even a larger number of cases to result seeing the vast extent of its use and abuse and also more frequent and more rapid cure on its complete withdrawal. In an epidemic of typhoid fever you would not be content to trace the cause to the milk only, but would pursue your investigations to the source of contamination. Would it not be more reasonable in this case also to investigate the condition of the nervous system which led up to the excessive use of alcohol and this would often take us back to that starting point which would suggest a very careful examination of the patient's eyes. The truly distressing condition of some of these neurasthenic cases suggests strongly to my mind that as there so frequently is a complete nervous breakdown, so if unrelieved there might be eventually a mental breakdown. I cannot help thinking that a thorough investigation of the previous history and a very careful examination of the refraction would result in some of the forms of insanity being traced back to those early manifestations of nerve troubles which have been shown to be due to eye-strain.

We have heard lately of pre-cancerous conditions and my suggestion is that we have also a premonitory stage in some of the forms of mental breakdown and that it is during this stage that so much may be done to avert disaster. T following is a suggestive and instructive case in regard this point.

CASE 14.—The patient, a woman, aged 38 years, was [illegible] had suffered intensely in her head [illegible] the last four years; not so mu [illegible] distressing sensations and a constant dre of going out of her mind. She suffered from great depr sion and nervousness and could not be prevailed upon to out by herself. She could not go to a theatre without mu suffering after it and, in fact, was practically debarred fr all social functions and quite unfit to attend to domes duties. She had been variously and greatly treated, h changed her place of abode several times, had had a cou of Weir-Mitchell treatment, she had consulted five differe medical men in Harrogate, a consultant in Leeds, a nearly all the medical men in a neighbouring town which she lived. She could see quite well without glas but promised to wear them as she would do anythi to get better. She persevered and very gradually b very surely improvement took place. In 18 months af I first saw her she was much better in every way, ca from her home to see me unattended by her husbar could go to theatres and attend to domestic matters, a life was now to her worth living. I have recently had further report from her husband who writes: "When wife first called upon you she was in such a state nervous prostration that she was totally unfit to perform go through the ordinary duties of life and I feel co fident that the wearing of spectacles enabled her to bat against her feelings and saved her from a mental brea down. For the past two years she has never been witho her glasses and now her health is nearly restored. M she now leave off the glasses out-of-doors?" This was very long-standing and severe case and some months elaps before very marked improvement was observed. Bearing mind her condition when I first saw her I can only endor the opinion expressed in her husband's letter.

I would suggest that in all cases of neurasthenia in whi error of refraction is present that it should become t routine practice to have that error corrected. If this skilfully done and the correction perseveringly worn by t patient I am quite convinced that those measures whi may be prescribed by the physician for the restoration nerve tone will be not only more rapidly successful but mo permanently so. I must ask you to receive these remar as far as possible with an open mind, not with the id of criticising my feeble attempts at the elucidation of su intricate and difficult problems but rather to try to find them some hints, some suggestions, to help you in yo efforts to throw more light upon those obscure subjects.

Harrogate.

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AN THERAPEUTICAL.

A CASE OF SNAKE-BITE.

By J. C. O. BRADBURY, M.R.C.S. ENG., L.R.C.P. LON

HOUSE SURGEON TO THE VICTORIA HOSPITAL, FOLKESTONE.

A SCHOOL-BOY, aged nine years, was brought to the Victor Hospital, Folkestone, in a cab on April 14th with the histo that he had been bitten by a snake which he had picked u on "Sugarloaf" Hill, near Folkestone, about three-quarte of an hour previously. On admission the boy had an anxio and livid appearance, rapid pulse, shallow breathing, a subnormal temperature (95° F.). He complained of feelin sick and had, his friends said, vomited six or seve times within five minutes of being bitten. There wa a punctate wound on the index finger of the righ hand, the skin around this spot being almost black; th whole hand was also swollen and œdematous, so that seemed useless to try to localise the poison by a ligatur The swelling increased rapidly and after a period of l hours the right hand, arm, and shoulder were much swolle There was also considerable ecchymosis of the skin, exten ing even as far as the right breast and halfway up the neck this was so marked about one and a half inches around the bite that it presented quite a gangrenous appearance The child was treated with hypodermic injections of strychnine Brandy and milk were also administered Locally hot boric fomentations were applied but the improvement which was at first marked was not maintained, as vomiting started again on the morning of the 16th and continued until 6 A M on the 17th Since then the boy has gradually recovered.

Dr W J Tyson, under whose care the patient was admitted and with whose permission I publish these notes, thinks the case of interest on account of the severity of the symptoms, showing that a large amount of venom was injected, the skin of the finger was exposed at the time of the bite so that there was no material such as a sock or a glove to mitigate the poison The variety of snake was unquestionably the viper (*Pelias berus*)

Folkestone

NOTE ON A CASE OF FATAL PERITONITIS FOLLOWING AN OVERDOSE OF PURGATIVE PILLS

BY J D STAPLE, M R C S ENG, L S A,
MEDICAL OFFICER AND PUBLIC VACCINATOR ASHLEY DISTRICT BRISTOL UNION

ON May 12th I was called to see a patient who was a married woman, aged 32 years, and the mother of two children She informed me that being "a few days over her time" she had taken seven Beecham's pills on the evening of May 11th and four similar pills on the night of the 10th She thought that this treatment "would set her all right" She stated that she had never had any illness I found her suffering from excessive diarrhœa and she said that she had vomited twice during the night On the next day the diarrhœa had practically stopped, no vomiting had occurred, but there was a considerable amount of abdominal tenderness On the 14th the symptoms of peritonitis were well marked and I called in Mr D O Rayner in consultation who concurred in the diagnosis and treatment The patient died on May 18th

The coroner decided to hold an inquest and instructed me to make a post mortem examination, which I did some 12 hours after the patient's death, Mr Rayner being also present We found extensive enteritis and peritonitis but the appendix was perfectly healthy There was no perforation but the inflammation involved all the coats of the bowel The internal organs were healthy and the deceased was not pregnant The jury returned a verdict that death was due to peritonitis caused by the excessive amount of pills I recently read an advertisement in one of the London halfpenny newspapers stating that "females especially will find that Beecham's pills will restore free and regular conditions," a statement which may certainly be described as somewhat ambiguous

Bristol

NOTE ON SUCCESSFUL VACCINATION AFTER THE ONSET OF SMALL POX

BY FRANK ROBINSON, M D VICT, D P H R C P S ENG
LATE MEDICAL SUPERINTENDENT BRADFORD CITY SMALL POX HOSPITAL.

IN a recent issue of THE LANCET[1] Dr J Coote Hibbert records a series of cases of considerable interest, especially to those engaged with any frequency in the differential diagnosis of small pox He attempted vaccination in 20 cases of small pox after the appearance of the eruption and obtained a successful result in 11 instances In four cases success is stated to have been evidenced by indurated raised papules, while seven presented typical vesicles Possibly a difference of opinion might be entertained with regard to the four cases in which the local evidence of success was indicated by papules The seven instances however, in which typical vesicles were obtained which ran the usual course of vaccinia would appear to establish Dr Hibbert's point that successful vaccination after the appearance of an eruption does not exclude a diagnosis of small pox

In a thesis[2] relating to small pox in Bradford in 1894 I recorded a similar series of cases to those of Dr Hibbert, which, I think, tends to strengthen his contention My notes are not now available, so I am unable to give a detailed account, but must content myself with quoting the broad facts as they appear in the thesis in question In 22 cases vaccination was attempted at dates varying from the first to the fifteenth day of illness, with failure in 14 instances The following are the dates at which vaccination was performed in the eight successful cases, two of which were of earlier date than Dr Hibbert's in two cases on the first day of initial symptoms, in two cases on the first day of papular eruption, in two cases on the second day of papular eruption, and in two cases on the first day of vesicular eruption It was thus found possible to induce vaccinia as late as the first day of vesiculation—i e, the third day of the eruption and the fifth of illness Dr Hibbert obtained vesicles in ten instances during the first four days of the eruption and papules on the fourteenth day in the eleventh case

A point of interest is the previous condition as to vaccination of the patients Dr Hibbert records that three of his 11 cases were not primarily vaccinated, while in seven of my cases there was no history of vaccination, and the eighth had but one fair mark and was 47 years of age The question as to whether vaccinia exerted any influence on the course of the attack in these cases naturally presents itself Dr Hibbert was unable to detect any modifying influence on the rash or on the course of the disease, and it may be noted that in two semi confluent cases vaccinated on the first and third days of the rash respectively, the vaccinia vesicles were very well marked Of my own cases, four were confluent in type, two were severe discrete cases, while two were mild in degree The confluent cases were very severe, were all primarily unvaccinated, and one out of the four proved fatal Of the discrete cases only one had been primarily vaccinated My impression at the time was that a favourable therapeutic influence was exerted by vaccinia, but the number of cases recorded is so small that one would hesitate to lay any great stress on that view Both Dr Hibbert's series and my own would, however, appear to establish the possibility of successfully vaccinating during the vesicular stage of small pox and possibly later This is a point of some importance in view of the strong tendency which Dr

result as a point

Medical Societies.

DEVON AND EXETER MEDICO CHIRURGICAL SOCIETY—A meeting of this society was held on May 12th, Dr J Mortimer the President, being in the chair—Dr R V Solly showed (for Mr G L Thornton) the following microscopic specimens (1) A Blood Film showing Malignant Malarial Parasites in the form of crescentic gametocytes free among the corpuscles (2) a Blood Film showing many Flagella of these parasites free among the corpuscles, (3) a Film Preparation of the Bacillus Pestis from Agar Culture showing well marked polar staining, (4) a Section of a Lymphatic Gland showing the Bacillus Pestis, and (5) a Film Preparation showing the Comma Bacillus, or Spirillum Cholerae Many involution forms were present—Dr Solly then gave a lantern demonstration illustrating, in the first place the life history of culeces and anopheletes and also the features by means of which the two genera may be distinguished in the egg larva, pupa, and imago stages A series of slides were then shown illustrating the sexual stage in the mosquito and the asexual stage in human blood of the three species of malarial parasites, benign tertian malignant tertian, and quartan Slides were exhibited demonstrating the peculiarities of the tsetse flies glossina morsitans, which conveys nagana, and glossina palpalis which conveys human trypanosomiasis or sleeping sickness, also the trypanosomes of these diseases and other varieties of trypanosomes, including the trypanosoma Tremanii found in the stone owl (athene noctua) and the wonderful transformations which it underwent in the stomach and the intestines of the common gnat, culex pipiens, as discovered by Professor Schaudinn These changes showed a great resemblance to the sexual cycle of the malarial parasite in the stomach of anopheles The subjects of the Leishman-Donovan bodies, the Congo floor maggot, and the jigger were also touched upon and illustrated.—Mr. J. D. Harris and the President made remarks on Dr. Solly's demonstration and the proceedings terminated.

[1] THE LANCET May 20th 1905 p 1337

[2] A Clinical Record of 220 Cases of Small pox. 1895. (Vict. M D thesis)

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held on May 26th, Mr. C. D. Fitch, the President, being in the chair.—Mr. J. Lionel Stretton showed two girls from whom he had removed large masses of Tuberculous Glands in the Neck. The first patient was 17 years of age and the glands which were removed weighed one and a quarter pounds. The second patient was 19 years of age. There was a large mass in the neck and at its centre a small scar where an attempt had been made to remove it six weeks previously in America. The growth was found to involve the right sterno-mastoid muscle and it was necessary to remove the whole of this, together with the jugular vein, through one incision along the anterior border of the muscle. The mass consisted of chronic inflammatory granulation tissue, containing many quite typical miliary tubercles. There was practically nothing to be seen of the nature of lymphatic gland, but at one place the process had invaded striated muscle. Mr. Stretton said that the case proved the implication of the muscle, which he had several times before been obliged to remove whole or in part. This experience, however, appeared to be at variance with that of some surgeons.—Mr. Stretton also showed a female child, aged three years, whose Wrist he had Excised for Tuberculous Disease. The whole of the carpus and metacarpus, together with the ends of the radius and ulna, were removed. The wound healed by primary union and there was a fair range of movement.—Dr. O. C. P. Evans showed a man, aged 48 years, the greater part of whose Right Elbow-joint he had Removed nine years previously for an Injury to the Joint. The ends of the radius and ulna had been taken away, the end of the humerus being left. The man had a very useful arm and could carry on his work as a farm labourer.—Dr. Evans also read notes of a case of a woman, aged 36 years, upon whom he had performed Cæsarean Section and Hysterectomy. The operation was necessitated by a rupture in the posterior aspect of the uterus complicating a hand presentation. The woman had previously had nine normal labours.—Mr. Dykes showed a case of Convulsive Tic and also read notes of a case of Aneurysm of the Innominate Artery which was being treated by needling and had diminished in size.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—A meeting of this society was held on June 3rd at Manchester in the Pathological Theatre of the Medical Department of the Victoria University, Dr. Thomas Barr, of Glasgow, the President, being in the chair.—Cases and specimens were shown by Mr. Pinder, Mr. H. E. Jones, Mr. F. H. Westmacott, Mr. L. Sewell, Dr. A. K. Gordon, and Dr. W. Milligan; and papers were contributed by Dr. P. McBride, Dr. J. Dundas Grant, Dr. Gordon, Dr. J. S. Barr, Mr. Westmacott, Mr. A. Wilson, Dr. J. D. Lickley, and Mr. Sewell. The most important items upon the programme were, however, a lecture by Professor W. Stirling upon Otocysts and the Ampullary Apparatus and a paper by Professor A. H. Young and Dr. Milligan on the Continuity of the Several Cavities of the Middle Ear.

Reviews and Notices of Books.

The Principles and Practice of Medical Jurisprudence. By the late ALFRED SWAINE TAYLOR, M.D., F.R.C.P., F.R.S. Fifth edition. Edited, revised, and brought up to date by FREDERICK J. SMITH, M.A., M.D. Oxon., F.R.C.P. Lond., F.R.C.S. Eng., Lecturer on Medical Jurisprudence at the London Hospital; Medical Referee to the Home Office. In two volumes. London: J. & A. Churchill. 1905. Vol. I., pp. 975; Vol. II., pp. 924. Price 36*s.*

THE first edition of this well-known work appeared in 1865. Its publication was due to the author's belief that a comprehensive treatise would be welcomed not only by medical practitioners but also by members of the legal profession and others specially interested in the subject. That this belief was justified was demonstrated by the fact that an edition was exhausted about every ten years. The fourth edition was edited by Dr. (now Sir) T. Stevenson. The present edition has been revised by Dr. F. J. Smith and a perusal of its pages well shows the admirable manner in which he has carried out a difficult and heavy task. The last 10 or 20 years have witnessed such unparalleled activity in all branches of the sciences ancillary to medicine in general and medical jurisprudence in particular that Dr. Smith has naturally had to make considerable alterations in the new edition. He has, in fact, found it necessary to rewrite almost entirely some articles and to recast the whole plan of the work in order to bring it into line with the results of modern research.

There is much interesting matter to be found in "Section I., Introduction." The manner in which coroners' inquests should be conducted is a subject which is being energetically discussed. The opinion expressed in this work is that the inquiry affords no certainty for the detection of crime, that it affords no protection to those who are wrongly charged with crime, and that in some cases it screens a criminal by a verdict based upon an imperfect inquiry in which the important medical facts are either not understood or are misinterpreted by the jury.

The main defects in the present system of holding inquests are considered to be: (1) in a large proportion of cases there is no post-mortem examination of the body by a qualified medical man; (2) in a small proportion even of those necropsies which are made the cause of violent death may be overlooked through the want of familiarity of the inspector with the signs of a violent death or with the steps necessary to be taken in a medico-legal inquiry; (3) the verdicts of coroners' juries are not infrequently ridiculous and quite contrary to the medical evidence; and (4) it is by no means unknown for a coroner to call no medical evidence whatever.

The remarks on Evidence are admirable and we can strongly recommend a perusal of them to all practitioners, for medical evidence is often very difficult to give in a thoroughly satisfactory manner. The section on Medico-legal Responsibility in the examination of a person, alive or dead, is also a most interesting one. The importance of obtaining the consent of an individual before he or she is examined cannot be too strongly insisted on and numerous instances are cited in which the neglect of this precaution led the medical witness into serious difficulties. The subject of identity, both of the living and of the dead, is ably dealt with. The completeness with which the matter is considered is shown by the fact that its discussion occupies 130 pages. A large number of cases are quoted illustrating the numerous difficulties which may arise.

In the first volume many other matters are described in the same complete and explicit manner. Amongst these may be mentioned the signs of death, survivorship, wounds and personal injuries, death connected with extremes of temperature, starvation, and death occurring from various forms of asphyxia. Sections will also be found on suicide in general, lunacy in general, lunacy in relation to the law, and also on life insurance.

The second volume contains sections on various medico-legal points connected with the reproductive organs and on toxicology. Some of the most difficult cases with which medical witnesses have to cope are those concerned with pregnancy, rape, abortion, and infanticide, and occasionally skilled evidence is required in cases of divorce, legitimacy, and paternity. It seems scarcely necessary for us to remind practitioners how important it is to acquaint themselves most thoroughly with every aspect of the subject in which they have to give evidence. Counsel on either side will have done so and although the witness may travel with perfect security over the thick ice of his examination in chief, yet the floating ice of cross-examination may present many dangers unless he is fully prepared beforehand with the knowledge acquired by careful examination and study. In the volume now before us the fullest details are given as to the numerous points that may arise and we can speak in high terms of the manner in which these important subjects are dealt with.

The portion of the volume dealing with toxicology is also characterised by the clear and thorough way with which each detail is considered. Each individual "poison" is described in a systematic manner under the following headings: source and method of occurrence, toxicity and fatal dose, duration, symptoms, treatment, post-mortem appearances, and analysis. A large number of poisonous substances are thus dealt with and this portion of the work is in every way most praiseworthy. The volume concludes with a chapter on Medical Jurisprudence in India by Dr. W. J. Buchanan, in which attention is drawn to those aspects of medical jurisprudence which are likely more especially to interest practitioners of medicine in India and other parts of the East under British rule.

In conclusion we may mention a special feature of these volumes—namely, the perfect mine of illustrative cases which they contain. Dr. Taylor's cases were chosen with much skill and his remarks on them were so judicious that in many instances Dr. Smith has left the descriptions intact. For his own part he has brought the work well up to date, some of the most recent judgments (one as recent as Nov. 9th, 1904) having been introduced. These cases are of the greatest value and the comments on them add considerably to their interest. We congratulate Dr. Smith on the successful result of his labours and consider that Taylor's "Principles and Practice of Medical Jurisprudence" as now edited is one of the best treatises on this subject in the English language.

A Text-book of Insanity. By Dr. R. VON KRAFFT-EBING. Authorised Translation from the last German Edition by CHARLES GILBERT CHADDOCK, M.D. Philadelphia: F. A. Davis Company. 1905. Pp. xvi.-638. Price, extra cloth, $4.00 net; half russia, $5.00 net.

THE late Professor von Krafft-Ebing's comprehensive work on Psychiatry, based upon 33 years of observation of the insane, is introduced to the English-reading medical world in the present translation. It is divided into three books, dealing respectively with the introduction to the study of psychiatry and general and special pathology and therapy. These books are composed of parts and chapters and the latter again of divisions and subdivisions, which system of exposition, whilst theoretically good, is likely to bewilder by its complexity. Instances of this could be given did space allow but we must content ourselves by referring to Part iii. of Book III. as an example. Throughout the work this tendency to divide and to subdivide is noticeable in what often appears to be an artificial and arbitrary manner.

Book I. gives a good historical review of the development of psychological medicine as a science. Dealing with the place of mental disease in the general domain of cerebral disease the author reminds us that the conception of psychoses as functional diseases may be given too wide an application and thus may encourage neglect of investigation of the pathologico-anatomical foundation of disease. We would add neglect also of bacteriological and chemical investigation, research in this relation being urgently needed. The author thinks it may be said "that there is not a single diffuse alteration of the cortex of the cerebrum, be it hyperæmia, anæmia, œdema, or inflammation, which does not manifest itself clinically by a disturbance of the psychic functions." We do not know that there is any evidence for this view in respect to the three first-named alterations; we are not, in the first place, able to admit that such alterations can be diagnosed.

Book II. deals primarily with disturbances of sensation, feeling, intellect, and will, of consciousness and of the motor, vaso-motor, trophic, and secretory functions in insanity. These matters are fully discussed; the author feels himself justified in giving definite teaching on what some would judge to be hypothetical matters. Here, also, he considers the causation of insanity, with its course, termination, prognosis, and diagnosis in general, together with general treatment. On these topics the usual lines are followed; all are thoroughly dealt with. We may refer more especially to the chapter on prognosis; the remarks on diagnosis also are very good. An outline for the examination of the mental state is given; we are pleased to observe that the author in his scheme includes the signs of degeneration, which he goes into rather fully, thereby emphasising his appreciation of the necessity for anthropometrical examination, which, we are glad to admit, is recognised in some asylum schemes in this country, although the general tendency is still to regard such work as superfluous and in the nature of a fad. Under treatment are discussed "means to prevent the fluxion of blood to the brain" (bleeding, diminishing the activity of the heart, dilating the peripheral vessels, and so on) and "means of increasing the flow of blood to the brain" (dilating the blood-vessels, facilitating the flow of blood to the brain, and the like). It may be doubted whether much of value can be achieved by such means. "Psychic" treatment is duly considered. As regards hypnotic suggestion, it is shown that this cannot be expected to succeed in insanity. We believe that the method has been discarded.

Book III., which comprises the greater part of the work, deals with the special pathology and therapy of insanity. The basis of classification of mental diseases of the adult brain assigns the latter to two classes according as they are accompanied by constant pathological lesions (organic psychoses) or not (functional psychoses). The former class comprises such states as acute delirium and dementia paralytica, and the latter mania, melancholia, and so on ("disease states of the normal robust brain") and paranoia, periodic insanities, and the like ("disease states of the abnormal predisposed brain"). The intoxication psychoses are a transitional group between the two classes. In this scheme holes may be picked as in all similar attempts, but we think that a classification on pathological lines is to be approved, even though it cannot as yet be elaborated for lack of knowledge. The disorders now commonly described under dementia præcox are discussed under the heading "stupidity or primary curable dementia," which condition is contrasted with melancholia cum stupore in the orthodox way familiar to students in the "eighties." The author considers it questionable whether hebephrenia can justifiably be regarded as a peculiar form of disease. We agree with him and apply the same criticism to the term "katatonia." The student, in our opinion, loses nothing by the absence of the usual chapter on this and other forms of "dementia præcox," which is at present *de rigueur* in the orthodox text-book. The different kinds of insanity are thoroughly described. A good account is given of the neuropathic condition and its manifestations. The author describes "hysteric psychoses" but we find the exposition of these states far from clear or convincing. We think it may fairly be said of this work that the style is often laboured and verbose. On p. 576 is the statement that dementia paralytica "may develop out of cerebral neurasthenia if the blood-vessels are abnormally permeable." Similar extraordinary statements are made with confidence in the course of this work. In fact, we do not think that pathology is a strong feature of the book which is rather that of a clinician. The various types of disease are copiously illustrated by cases from the author's large experience.

This is an elaborate work, suitable more particularly for the alienist and advanced student. Dr. F. Peterson of New

York introduces it with a biographical sketch of Professor Krafft-Ebing which is an interesting account of the life-work of the brilliant alienist of Gratz and Vienna.

Life Insurance Examinations: A Manual for the Medical Examiner and for all Interested in Life Insurance. By BRANDRETH SYMONDS, A.M., M.D. New York and London: G. P. Putnam's Sons. 1905. Pp. 214. Price 4*s.* net.

IN preparing this concise manual the author has been influenced by the desire to set forth the duties and the obligations of a medical examiner for life insurance. As a medical director of one of the American companies and as a lecturer on life insurance examinations he approaches his task with ample experience of the requirements from the official standpoint. That this book is addressed to the younger generation is evident in the prefatory pages, since the author discusses whether the course of instruction at a first-class medical school will enable a man to examine healthy people, and he holds that the condition of average health presents a problem for which he is not prepared; that an alert young practitioner hunts for some pin-hole defect which he magnifies through excess of zeal; and that an applicant for life insurance minimises his symptoms and diseases and has little or no sense of commercial honour when dealing with an impersonal thing like a corporation. These things a well-equipped practitioner might be expected to anticipate though the author thinks it is not reasonable to suppose that a man can have such knowledge intuitively. There is much of general interest in the historical account of life insurance and the section on fundamental points supplies important data relating to expectation, selection, insurance companies, and insurance policies. Much time and trouble would be saved if all medical examiners would act upon the directions laid down in the section on the relations between the examiner and the company; these are explicit and sensible and apply equally to all companies and all forms of life insurance. Although the author advocates a golden mean between antagonism and sympathy with regard to agents his remarks seem unduly charitable, since the weak point of all insurance companies is that the interest of the agents cannot coincide with that of the office. The chemical examination of the urine and the significance of cardiac murmurs are briefly discussed but the conclusion is that all deviations from the normal should be fully described for the information of the company with which rests the interpretation of the facts.

The Principles of Chemistry. By D. MENDELEEFF. Third English edition, translated from the Russian (seventh edition) by GEORGE KAMENSKY, A.R.S.M., of the Imperial Mint, St. Petersburg, and edited by THOMAS H. POPE, B.Sc., F.I.C. In two volumes. London: Longmans, Green, and Co. 1905. Pp. 1190. Price 32*s.*

OUR last marked reference to the great Russian chemist and his work was made in a leading article in THE LANCET of Feb. 27th, 1904, p. 591, in connexion with his views on the nature of the ether. Chemists are inclined to regard Professor Mendeléeff's chemical conception of the ether as speculative, but we are bound to remember that he has during his remarkable career made not a few speculations which have turned out to be, after all, an intelligent prediction of facts. Therefore we listen to what he has to say with respect. At any rate, no one could fairly convict him as a man of narrow views. On the contrary, his writings show the liberal spirit of the true philosopher. His views on the chemical nature of the ether are added in the form of an appendix to the volume before us. Advancing age seems to have impressed upon him the advisability of committing to print the ideas passing in his mind upon the constitution of matter and a great inducement to make these views known occurred when the phenomenon of radio-activity was announced. Shortly, his view is that the ether is an element lighter than hydrogen and that radio-activity really amounts to the emission of a peculiar rarefied ether gas capable of exciting the luminous vibrations. He anticipates adverse criticism but to some extent meets it by giving as his reason for making known his views that he has not many years for delay. "When I applied," he writes, "the periodic law to the analogues of boron, aluminium, and silicon I was 33 years younger than now and I was perfectly confident that sooner or later my prediction would be fulfilled. Now I see less clearly and my confidence is not so great. Then I risked nothing, now I do. This requires some courage, which I acquired when I saw the phenomena of radio-activity. I then saw that I must not delay, that perhaps my imperfect thoughts might lead someone to a surer path than that which was opened to my enfeebled vision." Here speaks the true philosopher and here is once more but another instance of a great master, old in years, confessing, as his great prototype Newton did before him, that in spite of the vast number of added facts and phenomena brought to his notice the *vera causa* seems as far off as ever. The volumes stand unrivalled in their clear and simple account of the principles of chemistry. But the work is not confined to the mere consideration of principles, for they constitute, as a matter of fact, an excellent source of reference for experimental data. Professor Mendeléeff has never failed to marshal just those facts to his aid which formed links in the chain of evidence. The number of chemical substances for which he has found a place in the index is remarkable; in fact, in a sense the work will be found to serve the purpose of a dictionary of chemistry so thoroughly and comprehensively has the author treated his subject. The present edition is practically identical with the previous one except that his chemical conception of the ether forms an article in the appendix, the corresponding place being occupied in previous editions by an article that has now been incorporated in the text of the book. The work is a classical contribution and both author and translator have acquitted themselves admirably. Moreover, the present issue has enjoyed the advantage of being edited by Mr. Thomas H. Pope.

The Edinburgh Stereoscopic Atlas of Anatomy. Section I. Contents 50 plates: Thorax, 1–15; Lungs, 1–3; Heart and Pericardium, 1–12; Mediastina, 1–6; and Central Nervous System, 1–14. The work to be issued in five sections each containing 50 subjects with descriptive text. Edited by DAVID WATERSTON, M.A., M.D. Edin., F.R.C.S. Edin., F.R.S. Edin., Lecturer and Senior Demonstrator in the Department of Anatomy, University of Edinburgh. London and Edinburgh: T. C. and E. Jack. 1905. Price, complete, £6 5*s.* net.

WE have examined with great interest the first section of this atlas and have already referred at sufficient length in these columns to the circumstances and auspices under which it is being produced. The series of 50 views now issued comprises illustrations of the thorax and the central nervous system and is subdivided into sections devoted to the thoracic walls, the heart and the pericardium, the lungs, the mediastina, and the brain. Fifteen reproductions of photographs are given of the thoracic walls, the pleuræ, and the pericardium; amongst these are special views illustrating the topographical anatomy of the heart and its valves. It is interesting to learn that these have been taken by a method of double exposure, first with the sternum and the costal cartilages in position and then after their removal. The results are very striking, the viscus being seen as through a semi-transparent covering and its relations to ribs and intercostal spaces are well depicted. A careful examination of the photographs of the heart thus taken and reproduced in this series shows that its relations vary somewhat from those ordinarily accepted as correct. The relations of the lungs and the pleural sacs, of the pericardium and of the structures in the upper aperture of the thorax, are all well shown. Only three photographs of the lungs are reproduced; these views are taken from above and in front and from the mediastinal aspects. It seems a pity that it was not found possible to illustrate the surface relations of the posterior parts of these organs. The views of the heart and the pericardium leave but little to be desired and convey a good idea of the shapes, the relations, and the connexions of the various cavities. The arrangements of the valves and the positions of the thin portions of the septa are well brought out. Some of the views of the mediastina appear to be rather complicated and it is not always possible to trace the pins which carry the guiding labels to their exact destinations in the depth of the pictures. In view No. 2 of the mediastina the vagus nerve appears to be indicated as the left superior intercostal vein and several of the labels are quite illegible. In No. 3 the right subclavian and the right *external* jugular veins are said to unite to form the innominate, an obvious slip. A beautiful series of photographs of the brain is given and these cannot fail to be of great use. They include views of the surface, of the ventricles, and of sections. We doubt, however, the wisdom of including a picture of the hydrocephalic brain; it seems rather out of place in an anatomical series. The stereoscopic effect of the pictures is excellent and they have evidently been most carefully prepared. The cards might have been issued in a stronger case with advantage as they are of considerable weight.

The Investigation of Mine Air. Edited by Sir CLEMENT LE NEVE FOSTER, D.Sc., F.R.S., and J. S. HALDANE, M.D. Edin., F.R.S. London: Charles Griffin and Co., Limited. 1905. Pp. 191. Price 6*s.*

THIS is a contribution of the greatest importance in connexion with the study of the constituents of mine air. In reality it is a collection of papers written by several authors on the nature, significance, and practical methods of measurement of the impurities met with in the air of collieries and metalliferous mines. Dr. Haldane, whose excellent work and inquiries on the subject are well known, has contributed a section dealing with rapid methods of analysis which have not been hitherto published. From time to time Dr. Haldane has made some valuable observations on the subject in official reports to the Government and we welcome in this collected form the information which he has gained by experience. He has designed methods of analysis in its special application to the examination of mine air, he has studied the question of the significance of the results, and he has given an excellent account of the effects of the impurities on man. His contribution in the present book on the interpretation of the analysis of mine air is most valuable.

The account given by the late Sir Clement Le Neve Foster on the effects of carbonic oxide in connexion with the Snaefell mine disaster in 1897 affords most interesting reading. His long confinement in the poisonous atmosphere was probably the starting-point of the illness which ultimately proved fatal. His devotion to duty was remarkable. He was intensely practical and was held in the greatest esteem by his co-workers and by those in whose life interests he laboured. It is doubtful whether a more graphic account has been written concerning the sensations, symptoms, and after-effects of poisoning by carbon monoxide. His coolness under the prospect of being left to die under the insidious action of carbon monoxide claims admiration. "How soon," he wrote, "I realised that we were in what is commonly called a 'tight place' I cannot say but eventually, from long force of habit, I presume, I took out my notebook. At what o'clock I first began to write I do not know, for the few words written on the first page have no hour put to them. They were simply a few words of good-bye to my family badly scribbled." Later he made a note of the time and at two o'clock he wrote: "Good-bye, we are all dying, your Clement; I fear we are dying, good-bye all my darlings all, no help coming, good-bye, we are dying, good-bye, good-bye, we are dying, no help coming, good-bye, good-bye." A few minutes later he wrote, "The box does not come. ..... I feel as if I was dreaming, no real pain, good-bye, good-bye. ...... We are all done." At length rescue was effected and the account of the stages of gradual recovery is of great interest. The anæsthetic action of carbon monoxide was evident from the fact that Sir Clement Foster experienced numbness of the fingers and he had, in fact, burnt his wrist and hand in a candle flame and had no notion that he had done so until a friend in the evening called his attention to a big blister. This was five hours or more after the burn.

Monsieur Léon Poussigue, manager of some French collieries, contributes an account of the methods there employed for the systematic examination of the air and control of the ventilation. The method of estimation of fire damp which is described should be studied by English mining engineers, as apparently it is as yet little known in this country. The first section is a translation of the treatise on the analysis of mine air by Professor Otto Brunck of the Royal Saxon Mining College, Freiburg. The instructions given are in simple terms and should be a valuable guide to mining engineers.

This book should be in the hands of all those concerned in the control of mining operations, for it is well calculated to fulfil the noble purpose of saving human life and preventing suffering.

LIBRARY TABLE.

The Arris and Gale Lectures on the Neurology of Vision. By J. HERBERT PARSONS, B.S., D.Sc. Lond., F.R.C.S. Eng. With two plates and 22 figures. London: Hodder and Stoughton. 1904. Pp. 70. Price 2*s.* 6*d.* net.—The title hardly fits the limited scope of the two lectures which make up this brochure. Lecture I. deals with the Afferent Visual Paths. Besides giving a *résumé* of the results already obtained the author adds some experiments of his own. It seems evident that of the two branches into which the optic tract divides as it turns round the cerebral peduncle the lateral root contains the visual fibres and ends in the lateral geniculate ganglion, while the mesial branch joins the mesial geniculate body and consists of fibres not connected with vision. The white line of Gennari, or Vicq d'Azyr, or of Baillarger in the cortex cerebri in the neighbourhood of the calcarine fissure has been known since the early part of the last century and this visuo-sensory cortex has recently been exhaustively investigated by Bolton These white fibres represent the terminations of the optic fibres. Lesions of the occipital lobe produce hemianopia without affecting the pupil reflexes. The fovea almost invariably escapes. Lesions of the mesial surface near the calcarine fissure produce the most serious disturbance for their size. The second lecture deals with the Innervation of the Pupil. There is a full historical introduction. The existence of a dilator muscle in the iris is admitted and the anterior layer of the retinal pigment epithelium is regarded as acting as a dilator muscle. Evidence by Szili goes to show that the sphincter pupillæ is also derived from the retinal epiblast. "These muscles, therefore, would resemble the arrectores pilorum of the skin in being formed from the epiblast." "Budge (1851-55) first seriously attacked the problem of the innervation of the pupil and it is only within the last few years that anything of importance has been added to his results, though they have been corrected in detail." This lecture gives these advances and corrections and anyone interested will do well to peruse this brochure. An excellent bibliography is appended. The author records his own observations on the effects produced on the pupil by stimulation of the cortex cerebri.

Hay Fever. By WALTER HERRIES POLLOCK and GUY C. POLLOCK. London, New York, and Bombay: Longmans, Green, and Co. 1905. Pp. 222. Price 3*s.* 6*d.*—Let no one be deceived by the medical title. This is not a serious contribution to science, in spite of its inclusion in the list of new books on science in the *Athenæum.* It is a very entertaining story-book where farcical episodes result from two causes connected with medicine. A copy of a prescription is given by a layman to a sufferer from hay fever and the directions on the bottle are obliterated by a splotch of sealing-wax. Many overdoses are taken and as the drug is cannabis indica the results afford material for amusement. The sufferer is a stockbroker and some excellent fun is obtained from the irresponsibility of his actions while under the influence of the drug. The lively note is well sustained throughout and, though temporary relief from hay fever is produced by cannabis indica, the book ends, as it starts, with a hearty sneeze. The moral is, Avoid untrained prescribers and shun overdoses.

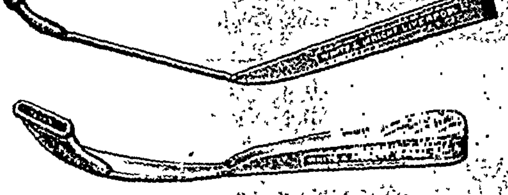
Les Rayons de Roentgen; Appareils de Production; Modes d'Utilisation; Applications Chirurgicales. Par EDMOND LOISON, Médecin-Major de 1re Classe, Professeur Agrégé du Val-de-Grâce. 1 volume in-8vo de 680 pages, avec 1191 figures dans le texte. Paris: Octave Doin, Editeur. 1905. Price 10 francs.—This work is divided into three parts, physical, technical, and surgical. The first or physical part contains a description of the various electrical appliances which are utilised in the production of the radiations discovered by Roentgen. Space is not occupied with the elementary subjects which every medical man is either acquainted with already or can find in his books, but, on the other hand, very full information, theoretical and practical, is afforded from a radiological point of view regarding the more advanced branches of electrical production. The second or technical part, which is subdivided into five sections, is concerned with the choice and management of the different appliances under various conditions, including military operations, and in addition to radiography in general deals as well with chrono-radiography, endo-radiography, stereoradiography, and metroradiography. In the final section of this part the author treats of radiotherapy, including a *résumé* of what is at present known about the deleterious effects exercised by the rays. In the third or surgical part Surgeon-Major Loison depends upon his own personal observation. He has produced a most valuable contribution to the literature of a new subject.

L'Abus des Lavages d'Intestin. By Dr. CHARLES ESMONET of Châtel Guyon. Reprinted from the *Archives Générales de Médecine.* April, 1905. Paris: Guérin, Derenne, LLuis, et Cie.—In this little pamphlet Dr. Esmonet draws attention to the "detestable tendency" which patients exhibit to administer intestinal injections to themselves in spite of all the directions which their medical men may give them against the abuse of such injections. He quotes the case of a young woman who had suffered from muco-membranous colitis for six years. During the last four years she was in the habit, twice a day, of washing out her colon with an injection of two litres of fluid. She suffered from acute spasm of the colon and never had a natural motion. The injections were stopped and belladonna was prescribed when she rapidly recovered. Dr. Esmonet concludes by pointing out that intestinal injections have their uses but that when once the large intestine has been thoroughly evacuated the injections should be stopped.

New Inventions.

AN ELEVATING VAGINAL DIRECTOR.

IN a small number of gynæcological laparotomies drainage of the pelvis is of advantage. It is well to drain at its most dependent part—i.e., from the bottom of Douglas's pouch directly into the vagina—and in the experience of the writer the most efficient agents are the glass vaginal drainage tubes introduced by Sir William Sinclair. The creation of a communication between Douglas's pouch and the vagina, whether carried out from above or from below, may be a source of delay and sometimes of difficulty. It implies interruption of the operation, fouling of one or both of the operator's hands necessitating re-sterilisation or change of gloves, and, if performed from below, alteration of the position of the patient. The instrument figured abolishes these disadvantages. For want of a better name it has been termed an "elevating vaginal director." It consists of a handle with a rigid shank on the end of which is fitted a flattened tube which has a transverse measurement of one and a quarter inches. The edges of the tube are thickened to prevent infliction of injury. The assistant introduces the instrument into the vagina and guides its upper end into the posterior fornix. By depressing the handle the upper end of the posterior vaginal wall is lifted up carrying before it the peritoneum. Through these structures the operator can readily feel the margins of the flattened tube and in some cases can see their outlines. The operator should make certain that no bowel is adherent to the bottom of Douglas's pouch, and should carefully ascertain that the orientation of the instrument is correct. Palpation with the fingers at once shows whether the cervix lies, as it should, immediately in front of the flattened tube. The vaginal wall stretched across the latter is then incised with knife or scissors, the points of the cutting instrument being prevented by the tube from damaging any other structures. Before the withdrawal of the director the cut edges of the vaginal wall are examined for bleeding points. Subsequently the assistant guides a Sinclair's tube along the vagina into position. Thus the operator's hands remain at all times clean and unsoiled and the course of the operation is uninterrupted. In ordinary circumstances the vaginal wall can be lifted up to the level of the abdominal wound. When inflammatory processes have more or less fixed the pelvic tissues the [illegible] less but is quite sufficient to permit of [illegible] being made with an ease which contrasts strikingly with former methods.

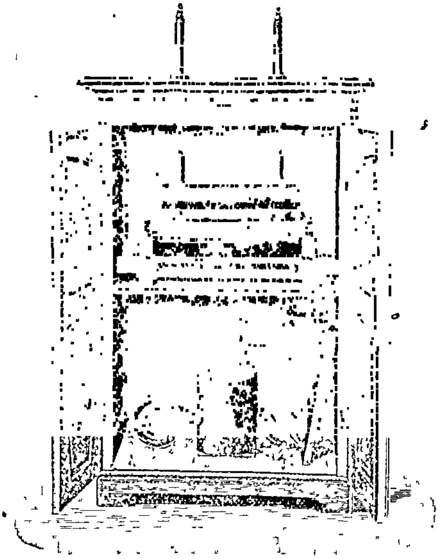


Messrs. White and Wright, Renshaw-street, Liverpool, have devoted much pains to the making of the director.

Liverpool. ARTHUR J. WALLACE, M.D. Edin.

A NEW HIGH TENSION TRANSFORMER AND A NEW FORM OF RADIUM APPLICATOR.

Messrs. W. Watson and Sons, of 313, High Holborn, London, W.C., are showing a new high-tension transformer for producing the x rays and high frequency currents, without induction coil or primary interrupter. It is made to work directly from the alternating current main. Where the supply is continuous a converter is provided to change it to alternating. The current is first led to a switchboard which is provided with the necessary measuring instruments and from which the whole apparatus is controlled. From this the wires go to the wooden cabinet which contains the transformer and the valve cell. This latter constitutes one of the chief features of the apparatus. It consists of a somewhat modified Nodon valve and is placed in series with the primary winding of the transformer. Its action is to suppress the impulses in one direction with the result that the primary winding of the transformer is supplied with a current which is more or less unidirectional. This valve will work for long periods of time without any attention. The secondary high tension current is thus also more or less unidirectional and can be used without further treatment for x ray work provided that a special bi-cathodal tube is employed. For ordinary x ray tubes a valve tube is provided which completes the rectification of the current. This valve tube is of peculiar design and will work for a long time without altering its vacuum to any material extent. The illumination of the x ray tube is very steady and the intensity of the light is under perfect control. The whole operation takes place in almost perfect silence, so quiet is the working of the apparatus. For high frequency currents the valve cell is cut out and the high tension alternating current is led directly to the high frequency apparatus which may be any of the types in ordinary use. The instrument is a distinct advance on the usual induction coil and interrupter.



The same firm are showing a new form of radium applicator made after the suggestion of Mr. T. J. P. Hartigan. It consists essentially of a thin quartz cover which permits a more full effect being obtained from the radium. The latter is hermetically sealed into the quartz by means of a silver back piece which may be attached to various carriers for application to the œsophagus, larynx, bladder, &c., the size of the applicator being practically that of a No. 12 catheter. It is also fitted with a metal cap somewhat after the style of a compass cover and the cap has a small slot cut on one side which will permit of the emanations being confined to any particular area.

A METHOD OF MOUNTING SECTIONS OF ORGANS FOR MUSEUMS.

A METHOD has been devised by Mr. F. F. Leighton of Bristol for exhibiting the cut section of an organ in such a way as to avoid the distortion due to spherical vessels or the difficulty of close examination when flat-sided vessels are employed. It is easy of execution and may prove of use to curators of museums. Thin slices of organs, prepared by one of the colour-preserving methods, are cut and mounted in shallow cells formed by cementing strips of plate glass, half an inch wide and one-fifth of an inch thick, to the edges of a flat glass plate. Old photographic plates which have been cleaned serve the purpose well. Canada balsam heated till it will set hard on cooling is used as the cement. After placing the section in the cell so formed a second plate is cemented over it. One of the strips forming the sides of the cell is cut short so as to leave an opening by means of which melted glycerine jelly can be poured into the cell and the section thus imbedded in the jelly.

BRANDY STERULES.

KNOWING how seldom it is that one can obtain a pure grape brandy when called to a case Mr. Martindale, chemist, of New Cavendish-street, London, W., has, at my suggestion, put up, in the form of his well-known "sterules," a brandy made from the grape. One or two of these brandy "sterules" can easily be carried in a small case as they take up very little space. It is only necessary to break off the top of the glass when one requires to utilise the contents.

STUART HALLOWS, M.B. Edin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on June 2nd, Mr. JOHN TWEEDY, the President, being in the chair.

It was resolved that diplomas of Fellowship should be issued to 35 successful candidates and that Licences in Dental Surgery should be issued to 50 successful candidates.

A report from the board of examiners in dental surgery was received and adopted. The Council decided: (1) To [illegible] surgery of the Dental Board [illegible] holders of such licence to [illegible] examinations together without previous passing of the preliminary science examination. Similar privileges were accorded to the holders of the degrees or licences in dental surgery recognised by the College, provided that they produce evidence (*a*) of having passed a satisfactory preliminary examination in general education, (*b*) of having completed the necessary curriculum of professional study, and (*c*) of [illegible] professional examinations for [illegible] dental surgery. It was also decided [illegible] of Part I. of the second professional examination all candi- [illegible]

[illegible] the Membership and Fellowship and Diploma in Public [illegible] In every case the examiners [illegible]

[illegible] that it had been arranged that [illegible] to the members and visitors of [illegible] held on Wednesday, July 12th, from five to seven [illegible]

A letter was read from Mr. Henry Morris reporting the proceedings of the General Medical Council at its late session.—The best thanks of the Council were given to Mr. Henry Morris for his services as the representative of the College in the General Medical Council.

A letter was read from Sir Alfred Cooper resigning his seat on the Council, as he contemplates retiring from practice in the near future.—The resignation was accepted with sincere regret.

The PRESIDENT reported that a meeting of the Fellows would be held on Thursday, July 6th next, for the election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir Henry G. Howse, Mr. Edmund Owen, and Mr. Rickman J. Godlee, and by the resignation of Sir Alfred Cooper.

The Fellows' subscription dinner will be held in the College on the evening of election day.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XV.[1]

THE PRESENT STATE OF MEDICAL EDUCATION—(*Continued*).

The Practical Unanimity of the Medical Scheme.—The Small Anomalies.—The Title of Doctor.—The London Medical Student.—The Falling off at the London Medical Schools.—The University of London to the Rescue.—The Separation of the London Medical Schools from their Hospitals.—Sir Edward Fry's Commission.—The Centralisation of Science Teaching.

IT has been seen that all medical education in England, through whatever portal the student intends to present himself for registration, is practically upon the same model, while the General Medical Council, in its intent to establish and to maintain a good and uniform standard, scrutinises the final tests of the corporations and societies from exactly the same point of view as is employed in scrutinising the universities. The result is that, roughly speaking, every medical student in the country receives the same education and is tried at the end of the same allotted period by the same tests. But this is to speak roughly indeed, as appears from the fact that the examinations of the Universities of London and Oxford have both recently fallen under the ban of the General Medical Council, although the last visitations have had such highly complimentary results, while at the same time the examination for the Licence of the Apothecaries' Hall of Dublin has been considered, after inspection, "sufficient," "sufficient" implying, of course, in the words of the Act, a standard which will "guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery."

But no one seriously supposes that the men who have taken their places upon the roll of the medical profession after complying with the educational requirements of the Apothecaries' Hall of Dublin have ever been better equipped for that profession than are the *alumni* of Oxford or London. It is true that we have in all cases the inspector and visitor of the General Medical Council, presumably on the same instructions, applying the same tests, seeing that the same provisions for fair examination exist, that the same regard is being paid to certain outlying provinces of medicine and surgery, and so on, with the apparent result that at one time there was greater fault to be found with the processes by which the student obtained the important hall-mark of M.D. Lond. or M.D. Oxon. than with those by which he is enabled to write himself down L.A.H. Dub. There can, it is suggested, be but one explanation of the position. Surely and sensibly, though in contradiction to the spirit and purpose of the law of the land, the General Medical Council inspects and visits the examinations of the different bodies from different points of view. The suggestion must not be made too much of, but none the less it must be made and its significance noted in connexion with the arguments advanced for the "one-portal system," the much debated measure of reform under which all medical men would be compelled to enter their profession by the passing of one State examination.

The important questions involved in the institution of such a State examination will fall naturally for discussion in a later chapter but it is impossible not to see that in many ways our present scheme of medical education, though it is practically unanimous in design, and though it is regulated by a coördinating authority, presents an awkward number of anomalous features. For example, in the examination schedule of one university the subject of "physics" includes the subjects "light" and "sound" and does not do so at another; "zoology" at one place and "biology" in another appear to mean the same thing; the medical student at Oxford who has passed his first M.B. examination is in the same stage of his curriculum as his brother student at Cambridge who has passed his second M.B. examination. Consider again the awkwardness of the multitude of medical titles, leaving aside for the present moment the vexed and most important question of who has a right to the title of Doctor. In England there are three corporations which can grant diplomas qualifying the possessors to be enrolled upon the Medical Register—viz., the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. Two of the titles bear the name of the capital and one the name of the country, but the limitations implied have no existence, so that apart from their historic reason the titles are silly and misleading. In Ireland, again, we have the Royal College of Physicians of Ireland, the Royal College of Surgeons in Ireland, and the Apothecaries' Hall of Dublin; in Scotland the Royal Colleges of Physicians and of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow. This means that in Ireland the diplomates of the Royal Colleges are named after their country and in Scotland after their metropolitan city, as the Irish Licentiates of the Apothecaries' Hall are named, but, again, the limitations are only apparent. Everybody can practise everywhere. Again, in the Royal Colleges of Physicians of all three countries the Membership is an honour diploma qualifying for admission to the Fellowship, the ordinary diploma being a Licence. In the Royal College *of* Surgeons of Edinburgh and the Royal College of Surgeons *in* Ireland (why this queer change of preposition?) the ordinary diploma is a Licence. At the Royal College of Surgeons of England alone the Membership is the ordinary diploma and there is no Licentiate. A Member of the Royal College of Physicians of London is the holder, that is to say, of an honour diploma enabling him, if he have positive and negative virtues and advantageous opportunities, to become a Fellow of his College, but a Member of the Royal College of Surgeons of England holds the pass diploma of his corporation entitling him only to a certain microscopic consideration from his corporation, so microscopic that some members may be heard to say in cold blood that their connexion with their College is absolutely valueless to them. All these anomalies make it very difficult for the public to understand that, not only from a legal point of view but from a professional point of view all medical men enjoy the same status—that is to say, that they all owe their places upon the Medical Register to the successful negotiation of examinations supervised by the General Medical Council in accordance with the Medical Acts. Those Acts provide but one class of medical men—viz., properly equipped practitioners of whom an official list has to be kept which the public may consult and so avoid the wiles of quacks. The public, however, do not understand this and the legal profession appears to understand it every whit as little. In the *Daily Telegraph* dated March 6th, 1905, there appeared an account of a police court case where a Licentiate of the Society of Apothecaries, giving evidence for the prosecution, was thus addressed by the solicitor for the defence: "Yours is the lowest degree a medical man can take." The legal gentleman, if correctly reported, was here rude and ignorant—rude because the words are not those which a member of a learned profession should address to a member of another learned profession; ignorant because there is no "highest" and "lowest" in the qualifications by which a man obtains the right to give medical evidence. If the exponents of the law are thus betrayed into vulgar error we can hardly blame the public for not understanding the legal position of medical men and for believing in the existence of some professional hierarchy.

But far more important to the medical profession than the smaller anomalies in style and title is the embarrassing fact that only those who graduate in medicine at one of the universities bear by academic right the style which is popularly granted to all medical men—viz., the title of Doctor. The diplomates of the Royal Colleges and the Licentiates of the Societies of Apothecaries are not able to style themselves "Dr.," though the public will not allow them to describe themselves otherwise. This is extremely galling for the diplomate, as the public cannot comprehend his not possessing the title by which they prefer to address their medical adviser. They are apt to regard him as an inferior man. Hence a never-ending subject of discussion among medical men and hence a position which must come within the scope of reform soon. "The man's the gowd for a' that", is more undoubtedly true about the practitioner in medicine than about the member of any section of the community and many a man possessing only the pass title of his corporation enjoys a position every whit as good socially and scientifically as his colleague who is a medical graduate, but this does not alter the fact that the classification into "Drs" and "Mrs" of the rank and file of the medical profession does a real injustice to a great number of men, especially to the London medical student whose peculiar position at the present moment must be considered in some detail

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., and XIV. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1039), and 29th (p. 1151), May 6th (p. 1218), 13th (p. 1287), 20th (p. 1375), and 27th (p. 1449), and June 3rd (p. 1533), 1905, respectively.

Twenty five years ago the average annual entry of medical students intending to take out their whole curriculum in one of the 12 London schools was little short of 700 It varied from 670 to 730, and to these there had to be added a fair number of students who having done their preliminary work elsewhere, joined a London medical school to complete their course by 'walking a London hospital During the "eighties" and "nineties" the common entry of general students at all the schools gradually dropped, now one school and now another appeared to suffer more than its fellows, but the story was one of regularly decreasing popularity of the London schools Dr J Kingston Fowler, the dean of the medical faculty of the University of London, who has made the position of the London medical student his particular care, has recently given,[3] upon the authority of the several deans of the schools, 424 as the annual average number of medical students entering for the whole curriculum in London during the period 1900 04 and having regard to the fact that figures so obtained would not constitute an under statement of fact, we should probably be safe in assuming that not more than 400 students are likely next October to enter for a complete course of medical education in London The broad significance of the desertion of London by the medical student must not escape us London is not only the capital of this country and this empire but it is a truly world's capital in a way and to an extent that Paris and New York are not If, as would appear self evident medicine and surgery can only be learned where men and women are congregated together in sufficient density to display numerous types of disease then it follows that London should possess the first medical school in the world An unexampled wealth of material should be utilised by the finest processes of tuition or the world is deprived of what it has a right to expect When a medical student turns his back for choice upon London and seeks his education elsewhere, when the famous hospitals of the metropolis do not attract him, when to reside at the world's headquarters appears to him to offer no rewards commensurate with its drawbacks, a serious position is implied By so much as the work done in the wards and out patient departments of the London hospitals is not utilised for educational purposes, by so much is our country placed at a disadvantage compared to others—we are wasting scientific opportunities The world is the poorer and Great Britain is especially the poorer The advantages of living in London and the field that is offered by London for the observation of disease cannot have escaped the attention of the student or his parents A huge seaport the seat of a court and a Government a teeming industrial centre finding employment for tens of thousands of operatives, a fashion and pleasure capital a focus around which 20 residential cities are more or less loosely grouped, and the money exchange of civilisation,—that is London, and such a city, or rather such a congeries of cities must have within its ill defined ramparts examples of all sorts and conditions of physical ill Before the student of disease would turn his back upon the opportunities thus offered to him he must feel that he would suffer in London from disabilities so serious as to annul the benefits

Readers of THE LANCET know the position so well that it can be put before them quite briefly, though the remedy is still, and will possibly for some time remain, the subject of debate These are the cardinal facts Medical education in London is in a displayed and confessed condition of muddle, the muddle is made worse by the shortage of medical students and consequent pecuniary loss to the schools, the London medical student cannot secure a medical degree upon terms which obtain elsewhere though his qualifications for a degree are undeniable How far these things depend upon one another is not as unquestioned as is the existence of the condition but the connexion is undoubted There are in London 12 medical schools each complete in itself and all offering to teach the medical student everything that he requires from the beginning to the end of his curriculum Each school possesses, in addition to lecturers upon, and demonstrators of, anatomy and physiology, teachers of all the ancillary subjects and each has striven to provide the necessary laboratories and class rooms for such an undertaking Fifty years ago the scope of the medical student's education being what it was, a medical school attached to a metropolitan hospital could easily provide all the necessary educational facilities for a student, 25 years ago the 12 separate schools were all working fairly satisfactorily as separate institutions, although those few persons who considered the matter outside their own immediate interests were able to prophesy imminent trouble Now the scheme has considerably broken down Since 1880 the expenses of medical education have been enormously increased The development of physiology the recognition of the intimate connexion between practical chemistry and biology on one side and pathology on the other the increase of our familiarity with electrical phenomena —these and many other advances in our scientific knowledge will occur to the mind at once as involving a medical school that would aspire to be completely equipped in grave expense All the London medical schools responded gallantly to the calls made upon them by the progress of modern medicine, some were enabled to do so much more completely than others but the story has been on every side one of unselfish profusion The medical education of England had to a great extent, been confided to the London medical schools and the men responsible for these schools made strenuous efforts, and for some time with no mean measure of success to meet the demands upon them But it has of late been borne in not only upon the authorities of the smaller medical schools but upon many connected v is useless to continue to in London of 12 separate co

Several of the larger hospitals might be able to maintain themselves as individual centres but amalgamation was seen to be the right course for the smaller schools To support in several places upon money that could be ill afforded a laboratory and a class room for the instruction by an unpaid teacher or a small group of lads was seen to be hopelessly uneconomic when one teacher in one class room could be paid to do the work properly And as the numbers of the London students began to drop off this position became clearer At first it led to increased expenditure by the smaller schools in the idea of attracting more students whose fees would justify the cost to the school—and in some cases to the hospital—of provision for an up to date education, but lately the futility of this course has been recognised For lately owing to several things, but chiefly to the reconstitution of the University of London whereby the medical schools of the metropolis became affiliated to the University the position of the London student became better understood It became recognised that to a great extent he was not deserting the London schools so much because he found the teaching in them inadequate as because for several reasons it was very difficult for him to obtain a medical degree

Immediately the subject of a medical degree for the London student is mentioned we are confronted with the dilemma that there is a medical degree available for him and for the rest of the empire—that of the University of London Why, asks the partially informed man does he not take advantage of what is offered to him? Or regarding the matter a little differently Why should the standard of the London degree be lowered that the London student may be able to pass the tests?

It is true that the degree in medicine of the University of London is of a high standard—probably when every branch of medical learning is considered with the examiner's eye the London degree is the best medical degree in the United Kingdom But it has not been wholly the intellectual difficulty of obtaining the degree that has kept the London student in greater numbers from competing for it—the fault has lain also and to an extent that has not been realised in the absence of any systematic teaching for London medical students directed towards their obtaining the London degree The 12 schools were strong some of them, in one direction and weak, some of them, in others In one school the dean seeing the paramount value of a medical degree, would exhort the student to obtain it; in another school the dean might not be over-interested in that matter or, indeed, in the students generally. The matriculation at the University of London undoubtedly was an obstacle to many students. This is still a test examination offering considerable difficulty to a lad on the threshold of a professional career, but the examination has now been made more reasonable in scope and design and should offer no insurmountable barrier to the properly taught student. And if he has some difficulty in the beginning of his career that is where difficulty should come, for the proper grounding that is insured by a searching, but not unduly hard, examination at the beginning serves the student an excellent turn later. A good general knowledge, which may be elementary but must be sound, of the preliminary subjects makes the rest of the curriculum so much simpler that the fortunate student who has begun by passing a fairly rigorous test can never understand the trials and vexations that seem to await his contemporaries at the hands of their examiners. At the University of London, after passing a distinctly high grade of matriculation the student finds himself confronted with a preliminary scientific examination which, again, is of the nature of an honour examination. Here the well-grounded candidate should be ready for the fray, but no soldier, however good, can fight effectively without weapons. And some of the London medical schools have not until recently provided the proper facilities for passing the examination. There is not a school in London, and there never has been, where an intelligent student of rather exceptional industry, bringing method to bear upon his work, could not pass the examinations for the London degree, but every student is not by nature orderly and industrious—nay, more, he may possess neither quality as they are understood by examiners and yet possess them both in a high capacity as a practical man for the practical issues of life. (Be it understood that examinations, whatever their purpose, are not [illegible] and that the medical examinations of [illegible] London are, and have been, in no way distinguished for their practical character.) These facts put a different construction upon the comparative failure of the London medical student to graduate in medicine at his University. It will be seen at once that the elements of chance have played a great part in his career and yet may do so. His school may not provide the necessary facilities or teachers; his classes in special subjects may be so small that the stimulus of competition may be much absent; his curriculum is not mapped out for him with a medical degree at the inevitable end; on the contrary, there are alternative tracks along which he can reach the Medical Register. All these things are obstacles to a smooth career and though they are frequently surmounted by young men possessing no vast claims to mental superiority still—now one, now the other, now all combined—they prove fatal to the efforts of many who in a more favourable environment would be able easily to satisfy intellectual tests similar to those of the University of London. It is a partial view, therefore, that regards the fact that a great many London students do not obtain a medical degree as a necessary reason for demanding the lowering of the standard for obtaining that degree. This is to shut our eyes to the truth that medical education in the metropolis at the present moment, in spite of much excellent individual effort, is a somewhat disorderly affair which requires consolidation and simplification very badly.

---

[3] The Times, Feb 22nd, 1905

The public as well as the medical profession has lately had a chance of seeing the situation clearly, for it was brought into considerable prominence at the beginning of this year by a valuable report made to the King Edward's Hospital Fund for London by a small committee consisting of Sir Edward Fry (chairman), Lord Welby, and the Bishop of Stepney (Dr. Cosmo Gordon Lang). This committee was appointed by the King Edward's Hospital Fund for London in response to a growing feeling that money might be diverted from the objects for which it was intended if hospital authorities, choosing to consider their hospital and its attached school inseparable bodies, should make up the deficiencies in the school accounts out of moneys received for the charitable institution. The terms of reference to Sir Edward Fry's committee were very simple. The members were asked to consider and to report whether any money given or subscribed for the relief of the sick poor to the 12 London hospitals having medical schools is used directly or indirectly by all or any of those hospitals for the maintenance of medical education. The arrangements of the hospitals exising in January, 1905, were to be taken as the subject of the inquiry, and the committee was asked also to report, in the event of any hospital subsidising its school out of money properly belonging to the hospital, whether the hospital received an adequate return for such subsidies. The committee got to work with commendable promptitude, being a small and thoroughly competent body with definite issues before it, and made its report at the end of February. The report found that two hospitals only out of the 12 could be acquitted of the charge of subsidising their schools out of hospital funds; that two medical schools could not be ascertained to be clearly deriving any pecuniary benefit from their associated hospitals; and that all the other eight medical schools directly or indirectly received contributions from hospital funds. With reference to what repayment was made by the medical schools to the hospitals for their subsidies the committee reported that no return was ascertainable from the schools which could be held to recoup the expenditure of money upon pathological and bacteriological laboratories, though it was allowed that the schools supplied the hospitals with a valuable amount of skilled gratuitous service. Finally, the commissioners added to their report the following paragraphs[3] which were only loosely related to the terms of reference but which are of the greatest value as showing a sound appreciation of the position of the London student:—

> "25.—We have formed the opinion that a broad line of distinction ought to be drawn between the studies of the first three years of a medical student's curriculum and the studies of the last two years—or, in other words, between the preliminary and intermediate studies on the one hand and the final studies on the other; and that whilst the latter studies can only be pursued with advantage within the walls of a hospital and nowhere in the world with more advantage than in London, the earlier studies have no real relation with a hospital and are therefore more properly to be pursued in an institution of a university character; and further, that the attempt of many of the hospitals to associate with themselves schools teaching the preliminary and intermediate subjects is a great, if not the chief, source of the exhausted condition of the funds of many of the schools and the consequent demand of the schools on the funds of the hospital.
>
> "26.—It is therefore with great satisfaction that we find that the statutes of the University of London (Paragraph 80) direct the Senate to 'use its best endeavours whenever practicable to secure such common courses of instruction for internal medical students in the preliminary and intermediate portion of their studies under appointed or recognised teachers at one or more centres'; and if this object can be carried into effect we believe that it will free some of the schools from burdens which they find it difficult to bear."

These paragraphs were seen at once to strengthen enormously the hands of those who believe that in the reconstitution of the University of London lies the salvation of the London student. A central school at the University, or two or three central schools founded as integral parts of the University, would secure for the London student proper education in all the preliminary parts of the examination. He would be taught by well paid professors in well-furnished laboratories—he would, in short, enjoy a proper educational training, well organised, and well directed to a definite end as does his brother student in Liverpool or Edinburgh.

The efforts of the present teachers of the introductory and ancillary subjects in London must not be despised any more than must those of a small hospital, desperately short of money, which founds and tries to support all the machinery for a modern scientific medical education at the cost of £5000 or more. The hospitals and schools of London have struggled manfully to deal with the situation. They have strained their resources—one or two of them to snapping point—in their endeavour to fulfil their proud functions of the past and their lecturers and demonstrators have gallantly seconded their efforts by doing admirable unpaid work. But the students are not attracted and without the students the struggle cannot and need not be continued.

The common experience of those who have interested themselves in the London student, no less than the report of Sir Edward Fry's committee, shows these three things and we have to make up our minds to what degree they are inter-related. We have—(1) a decided falling off in the numbers of the London students; (2) a system of medical education that is manifestly faulty as well as uneconomical; and (3) undoubted difficulty in obtaining a medical degree in London. Cannot all these three things be related so that if the University of London can provide the proper scheme of education the students will return to the London schools where the best clinical material for their later studies may be obtained? And should not the degree of the University of London be secured by a good proportion, say 75 per cent., of the students when they receive proper teaching to that end? I believe so, and I do not attach great importance to the cry that a medical degree for London students implies the lowering of the standards of the degree of the University of London. With considerable disadvantages the London medical student as a rule takes the diplomas of the English Conjoint Board and we know that this final examination is of a really high character. Those qualified by the Board take high places almost invariably when they enter for competitive examinations; and the number of men who, possessing the double diploma of the London Conjoint Board, reach high positions in private practice and in public appointments is great. These things go to show that the want of a medical degree to the London student is an accident due to faulty arrangement, but an accident which may militate so seriously against his future career as to have decided many students to seek their medical education elsewhere than in the metropolis. Many hospitals—London and provincial—all the important ones in fact have laid it down that their medical staff shall be graduates in medicine. The mere diplomate, though he may be known to have passed an examination that would have amply secured for him a doctorate at centres other than London, cannot compete for posts at hospitals against the holders of medical degrees of any sort. And in private practice he is liable to be told that whatever the people may call him he is not a "real doctor." The London student knows all this too well, and the columns of THE LANCET have borne frequent testimony to the reality of the grievance that has been suffered, and still is being suffered, by the London student. But the situation has not as yet been remedied.

---

[3] See THE LANCET, Feb. 25th, 1905, p. 521.

The question is, Can the newly constituted University of London come effectively to the rescue? There is no doubt that the Faculty of Medicine of the University has done its best to meet the case. When the Senate of the University came into office it recognised the obligations imposed upon it by statute and requested the Faculty of Medicine to consider the position of medical education with the view of reform. The Faculty of Medicine consisting of some 400 recognised teachers many of whom are connected with the London medical schools appointed a committee from which it received an important report. The gist of the report can be realised from its result, for a movement was at once inaugurated for the foundation of an Institute of Medical Sciences to serve as a central school for the education of the students of the University in those subjects the study of which must precede professional study proper—which would necessarily be undertaken at a hospital. An appeal was made to the public signed by Lord Rosebery, the Chancellor of the University, and all the chief officers of the University begging for the immediate support of an Institute of Medical Sciences. This appeal was received by the whole of the press of London with outspoken approval and met with a prompt return, several munificent donations being received. Subsequently a letter signed by the treasurer or chairman of every London hospital concerned was addressed to the Chancellor of the University endorsing the action of the Senate. All these important and responsible officials, who had been compelled by the positions which they held in connexion with the general hospitals of London and their medical schools to give the proposal that the University should undertake the teaching of the preliminary scientific subjects of the medical curriculum the most serious consideration had come to the same opinion. They were convinced, and had no objection to saying so publicly, that the adoption of the recommendations of the Royal Commission in favour of the concentration of the teaching of the preliminary subjects had become a matter of urgent necessity in the interests alike of the hospitals and the medical schools.

It must not be supposed that this opinion is held unanimously by all London medical teachers; on the contrary, there are teachers at the London medical schools who consider the plan of fusion of all the schools into one central institute, as far as the purely school subjects are concerned, to be a mistaken policy. They admit that the smaller schools depend for their very existence upon some amalgamation scheme and think that these schools might well enter into a form of combination among themselves for courses in the non-professional scientific subjects, leaving anatomy and physiology still in the hands of each hospital school. The larger schools they consider might, being affiliated to the University of London, be helped by the University with any money that the University can raise for such educational purposes, but it seems in their opinion unwise to dissociate all preliminary science teaching from the teaching of the purely professional subjects (which must be taught at a hospital) because day by day practical medicine is becoming more and more dependent upon laboratory inquiry. The opponents of a scheme of centralisation use the argument of economy every whit as keenly as its advocates, as can be seen by reference to Mr. Henry Morris's able oration delivered before the Medical Society of London on May 15th and published in THE LANCET of May 20th, p. 1313. Much money has already been spent upon perfecting the medical schools of the various hospitals and to a certain extent this money will be wasted while much more money is yet required before the Institute of Medical Sciences becomes a possibility. But the wastefulness of removing the study of the preliminary sciences from these numerous newly constructed institutions is not as great as it looks. Annual subsidies from the University to the different efficient centres would mean year by year a set of separate smaller payments that would in the aggregate amount to more than the one set of large payments necessitated by a central institution, while many more chances of maladministration would be introduced. Again, the money already subscribed for and spent at the separate medical schools will not be wasted entirely, or even at all. The laboratories intended for the pursuit of physiology and chemistry, can all be employed for those sciences medically applied—i.e., for pathology. There is great and immediate need in London for improved clinical and pathological laboratories if London is not in this respect to drop behind the provinces, for everyone recognises as the most salient characteristic of modern medicine its association, through pathology, with chemistry and physiological chemistry, an association which grows momentarily more intimate. None of the money spent on bringing medical schools up to date will be wasted. The laboratories can simply be used to supply other needs that are very severely felt. The huge size of London is an argument against making it compulsory upon all students to attend one place and one only, but there might be one Central Institute of Medical Sciences at the University of London and two others perhaps auxiliary to it; there can be no doubt however that economy will be best served by the concentration of the science teaching of the medical student in one, two, or perhaps three centres.

These things have occurred of course to the minds of the Senate of the University of London, for this body has lately appointed a committee to confer with representatives of University College, London, and King's College, London, and of the schools of the University in the faculty of medicine as to the practicability of securing common courses of instruction in the preliminary and intermediate subjects of medical study at University College and King's College, such common courses to form part of a scheme for the concentration of the study of those subjects in the University. The wish is to utilise to the full extent the existing opportunities for concentration afforded by University College, London, as a northern centre and King's College, London, as a southern centre while waiting for the foundation of a Central Institute. It is recognised that the resources of University College and King's College are inadequate to accommodate all the students at present in the London schools and for a time it will be necessary to continue the teaching of the preliminary and intermediate subjects at some of the schools. Naturally it will be the larger schools—those of St. Bartholomew's Hospital and London Hospital, for example—that will remain for some time unchanged and it is at these schools that permanent resistance to a complete centralisation scheme may be expected. Every school naturally resents being forced into a centralisation scheme, for any method of amalgamation wears the appearance of confessed weakness, and the large schools where as yet no urgent necessity presses for the strength that comes from union, may well be expected to make a fight for individuality. Conscious of having done their work thoroughly well they do not see why they should give up doing it and the feeling is one with which we must all sympathise.

Yet in the interests of the London student we must wish earnestly to see the day of amalgamation approach. The larger schools may say that it is not the inefficiency of their teaching that has caused the dearth of London students; but rather the facilities offered by other medical centres for attaining a medical degree. To this the reply is that equal facilities can only be obtained under an amalgamation scheme. Such splendid work has been done by London teachers in adverse circumstances, and in return for little or no payment, that it would be indeed ungracious to suggest that the quality of the teaching is not what it was, but without making any such suggestion it is undoubtedly true that some of the best London teachers are snapped up by other medical schools and well paid by them. So that again centralisation appears as the remedy for existent evils. The bringing of all the medical students of London, at the beginning of their career, into one of two or three schools which are not connected with this or that hospital but which form an integral part of the University of London would naturally turn the student's eye from the beginning of his career upon the M.D. of London as his proper goal. All his early education would be towards that end, and being systematically instructed, he would not find the purely scientific examinations so hard as to form an unjust barrier against his legitimate aspiration to be a medical graduate of his university, thus escaping the drawbacks of professional life without the title of Doctor.

Amalgamation will certainly take a step forward quite shortly and we shall then have practical experience of its value to the London medical student. To prophesy that it will to a great extent remove his grievances may seem over sanguine, but is it? At a central school he will receive from selected teachers proper training. He will then go to his hospital well grounded in science, well prepared for future teachings, and definitely embarked upon an attempt to obtain a medical degree. At the hospital he will receive the individual attention that at a central school he may have lacked, and his practical education by the bedside can hardly fail to be improved by the lightening of the educational burdens of his teachers—the medical staff of the hospital. There seems to me no reason why 75 per cent. of the London students in such circumstances should not obtain the medical degree of their university with no undue delay and with no series of merited or unmerited "ploughings." And when this position is reached it will surely mean that London will again be recognised as *par excellence* the centre of the world for medical education.

(To be continued.)

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 9, 1827.

In my preceding letters upon the subject of the Royal Commission for visiting the Universities of Scotland, I stated that the inclinations of that body are believed, by those who are more immediately to be affected by the changes that may [illegible] introduced, to tend towards recommending an assimilation, in respect to medical discipline, of the Scotch to the English Universities, by an extension of the period of medical education in the former from *four* to *eight* years, the first half of that period to be consecrated to what is called preliminary study. The writers also on this subject, in Scotland, by whom the Commission are [illegible], or whom they may deign to prompt, are earnest in recommending, for *all* the branches of the medical [illegible], what they call a *due* and *adequate* course of preliminary education, without condescending to explain, or [illegible] knowing themselves what precise meaning they would attach to these words. They do not favour us with either a *maximum* or a *minimum*. But, of course, according to their doctrines, the more the young medical brain is saturated with collateral knowledge, before it receives any of a strictly medical nature, the better. If they be sincere in these opinions, I can only say it appears to me that a species of epidemic insanity prevails in [illegible]; and, if otherwise, that they are only [illegible] vocation—exercising [illegible]." This doubling [illegible] considered by many [illegible] double the expen[illegible] to the student, [illegible] cultivation of medicin[illegible] of the community. [illegible] to the public, and is who[illegible] spirit of the institutions of a free country. On the part of the student, it would be a grievous waste both of time and money, for which he could not reasonably hope, by future professional exertions, to obtain adequate remuneration. But this is not all; for as I said, in one of my former letters, "unless the head of the medical student have an infinite capacity for knowledge, the less it is loaded with attainments not necessarily connected with medicine, the more it is likely to imbibe of strictly professional acquirements." I therefore concur with Dr. Duncan, jun., that, "in devising plans for the reform of the education of professional men, it is of the greatest consequence to keep constantly in view the distinction between those kinds of [illegible] and scientific knowledge, which are a[illegible] to the safe exercise of the professi[illegible] is desirable, and for the interest of the practitioner that he should possess, and those which are merely ornamental. "[illegible]tem," says he, "which will have a t[illegible]glect any branch of which he ough[illegible] never be compensated by any ext[illegible] those of which his ignorance is harm[illegible]. Medicine is a practical profession. That knowledge is most essential to the students, which renders them the most useful servants of the public; and all reputation for extrinsic learning, which is acquired at the expense of practical skill, is meretricious, and deceives the public by dazzling their judgment."[1]

---

[1] Excerpt from a letter to the Editor of THE LANCET, dated London May 18, 1827, and signed "An Anti-Monopolist, C."

UNIVERSITY OF CAMBRIDGE.—On June 1st Mr. Beck, Master of Trinity Hall, was elected Vice-Chancellor for a second year.—The spec[illegible] has proposed a scheme by [illegible] and M.D. degrees who are [illegible] all their examinations ma[illegible] *absentiâ.*—A studentship in [illegible] in the University in memory [illegible] Anthony Wilkin of King's College.—Dr. L. Humphry, Dr. S. West, Dr. W. Hale White, and Dr. J. Rose Bradford have been appointed examiners in medicine; Dr. W. Rivers Pollock and Dr. M. Handfield-Jones, examiners in midwifery; and Mr. T. H. Kellock, Professor H. G. Barling, Sir Hector C. Cameron, and Mr. C. W. Mansell Moullin, examiners in surgery for the ensuing academical year.

NATIONAL HEALTH SOCIETY.—The annual distribution of medals and certificates given by the above society took place on May 30th at Grosvenor House, London, W. Princess Christian handed the awards to the recipients and Lord Derby presided. Amongst those present were Sir William Church, Sir Frederick Treves, Sir William Broadbent, Sir Thomas Smith, Sir James Crichton-Browne, Dr. Robert Hutchison, and Dr. Clement Godson. Sir William Church, in proposing a motion to the effect that the work of the National Health Society is deserving of all support, its object being the diffusion of the knowledge of the laws of health among all classes of the community, especially among women, who are responsible for the hygiene of the home and the rearing of healthy children, said that during its 32 years of existence the society had done incalculable good. Sir Frederick Treves seconded the motion, remarking that though the report of the Privy Council Committee on Physical Deterioration revealed nothing of a very alarming character it had certainly shown a state of affairs which was not creditable to the country. It was within the province of the National Health Society to find a remedy for the evils shown to exist by that Committee. The motion was adopted and a vote of thanks to Princess Christian, who is president of the society, terminated the proceedings.

THE LANCET.

LONDON: SATURDAY, JUNE 10, 1905.

Air-borne Infection from Small-pox Hospitals.

IN THE LANCET of June 3rd, p. 1520, we referred to the excessive local incidence of small-pox which has so often been traced when hospitals receiving acute cases of this disease have been situated within or near populous neighbourhoods, and to the remarkable evidence of this characteristic "hospital influence" which has been afforded by different epidemics during the last few years. We revert to the subject in order to consider the trend of recent discussions on the cause of these repeated manifestations of small-pox "hospital influence." More than twenty years have passed since Mr. W. H. POWER suggested that the infective ability of particulate matter derived from acute cases of small-pox was not necessarily limited in its range to the room containing the patient or to the interior of a hospital in which small-pox patients were under treatment. At that time, as now, the high degree of infectivity (to unprotected persons) of the atmosphere of a small-pox ward or sick room was generally recognised and was attributed to what no doubt is its true cause, the presence in the air of an abundance of floating particles derived from the affected portions of skin and mucous surfaces. Mr. POWER, recalling familiar facts respecting the transit of various kinds of floating particulate matter for considerable distances through the open air along lines of definite convection currents, suggested that in course of the many days in which a small-pox hospital is used during an epidemic occasions now and then arise when infectious particles carried upwards from the hospital are conveyed by local air currents to places in the neighbourhood of the hospital without undergoing any great degree of dispersion. The hypothesis of "aerial convection" depends on an assumption of the probability that this may occur. The necessity for the hypothesis was that it afforded a consistent explanation of the sum of the facts which had then been ascertained with regard to "hospital influence": in particular the recurrence and the persistence of small-pox round the same hospital in different epidemics; the manifestation of "hospital influence" at different hospitals, notwithstanding strict administrative precautions and close supervision over the incomings and outgoings of nurses, porters, visitors, and ambulances; and the fact that the exceptional incidence of small-pox was seemingly independent of the lines of communication and traffic to and from the hospital but was distributed in all parts of the neighbourhood of the hospital. It afforded an explanation likewise of the otherwise perplexing circumstance that the incidence of small-pox on houses near the hospital was graduated in its intensity, the percentage of houses attacked becoming less as the distance from the hospital increased. Moreover, Mr. POWER found that manifestations of "hospital influence" coincided with meteorological conditions (especially calm days, or days with light and variable airs from almost any part of the compass) which would favour local convection currents of the kind supposed. The alternative theory that all these phenomena of "hospital influence" had resulted in some way or other from personal communication and traffic was tested by Mr. POWER in a variety of ways but after prolonged inquiry failed to afford any adequate explanation of the facts. Since Mr. POWER'S work numerous other instances of "hospital influence" have been investigated and analysed on similar lines and with like results. When it has been possible to give the labour necessary to ascertain the proportion of houses attacked at different distances from the hospital clear evidence of graduation has practically always been obtained. In the case of some hospitals, however, the position has been complicated by the inadequacy of the buildings, by overcrowding, mismanagement, and insufficient supervision of patients and staff. Accidents such as the escape of patients from the hospital grounds have occurred, and there has been clear evidence of communication between patients within the hospital inclosure and persons outside. So that in these cases, whatever may have been also taking place as to aerial convection, it has been evident that opportunities have been afforded for small-pox to spread in the neighbourhood of the hospital by personal communications. It has been maintained in view of these instances that, if only the facts could be fully known, "hospital influence," wherever and whenever it has occurred, would be found to have resulted wholly from personal infection of this kind. This view was developed and skilfully defended by Dr. A. NEWSHOLME in the recent discussion at the Epidemiological Society. The argument is that it is practically impossible to prove a negative; that it is therefore impossible in the case of the best-administered hospital to say that no communications have taken place between patients or infectious members of the staff on the one hand and persons living near the hospital on the other; and that the hypothesis that numerous and persistent communications of this kind have, after all, occurred is always to be preferred to the hypothesis of aerial convection.

The difficulty in accepting this position, however, is that it involves a series of assumptions—for example, a continued series of visits by infectious patients or staff to houses all round the hospital, graduated in inverse relation to the distance—which, when applied to a number of hospitals in different situations and under widely different conditions of administration, impose a far greater strain upon the imagination than any involved in the aerial hypothesis. And the most recent examples of "hospital influence" are by no means easy to reconcile with Dr. NEWSHOLME'S theory. As Dr. BUCHANAN pointed out, the hospitals lately concerned have been those of cities which leave little to be desired in the way of hospital organisation and administration and readiness for emergency. Nevertheless, Liverpool has been unable to prevent "hospital influence" being exerted by each of its three small-pox hospitals, while in Glasgow the characteristic spread of the disease has been manifested year after year in four successive epidemic periods. In the case of the hospital ships in Long Reach it would be necessary to assume numerous and periodic communications between patients or staff and a variety of persons on the opposite bank of the Thames, nearly half a mile away, an assumption for which there seems to be little warrant. A further difficulty arises in explaining the case of Gateshead, where the "hospital influence" was mainly felt, not in Gateshead itself, the place from which the patients came and which furnished all the hospital traffic, but in the district of Felling, which sent no patients to the Gateshead Hospital and had no traffic or other communication with that hospital. Nor can the hypothesis of unknown personal communications be reconciled with the experience of Monsall Hospital which Dr. J. NIVEN related to the Epidemiological Society. Here in the course of a few days small-pox appeared in four separate wards of the fever hospital which adjoined the small-pox hospital, while at the same time an outbreak occurred in the neighbourhood beyond. Not only did inquiries fail to trace personal communication in either set of cases but it was evident that any assumption of unknown communications which could explain the fever hospital cases could not also account for the outbreak outside and *vice versâ*. On the other hand, both outbreaks were readily explicable by aerial convection, which would have been favoured by the prevailing meteorological conditions. It is well known that no indication of "hospital influence" has been obtained in the case of hospitals containing patients suffering from other diseases usually received into isolation hospitals, scarlet fever, diphtheria, or enteric fever, or in the case of hospitals receiving only convalescent cases of small-pox. When patients in the acute stage of these four diseases are compared it is probable that small-pox, by reason of the character and abundance of its rash, would be capable of causing the highest degree of contamination of air with infective matter. In this connexion Dr. NIVEN's recent experience of the absence of small-pox from the neighbourhood of Clayton Vale Hospital at a time when the skin of all the acute cases was kept thoroughly and systematically oiled or was protected by means of special dressings deserves mention. If in future epidemics it should still become necessary to use hospitals in populous neighbourhoods for small-pox or to treat small-pox patients at their homes Dr. NIVEN's system of minimising the risk of aerial contamination would seem well worthy of trial.

"Toujours en Philanthrope."

IT can very rarely happen that a book which is in its essential nature an autobiography, and still more rarely one which is the autobiography of a non-medical writer, can call for such notice at our hands as is implied in making it the subject of a leading article; but the volume entitled "In Peace and War," recently published by Sir JOHN FURLEY, appears to us to be worthy of such an exceptional distinction. It contains the record, for something like 40 years, of a life which has been almost continuously devoted to the organisation of assistance for the wounded in war and also, in the intervals between campaigns, to the best methods of bringing "first aid" to the victims of accidents in peace. It covers the period from the outbreak of the war between Germany and Denmark in 1864 to the close of our own recent struggle in South Africa and it brings vividly before us, with all the force of simplicity, something of the lives and the acts of the great civilian surgeons who have carried their skill to so many battle-fields, as well as of those of their more strictly military colleagues. Unlike many of the people who from time to time declare their "great interest" in medical science, Sir JOHN FURLEY makes no pretence to the possession of professional skill or knowledge and he certainly would never volunteer an opinion, in any given case, either as to the course which it would be judicious for the surgeon to pursue or as to the probable results of his ministrations. The work which he made his own was to secure that, wherever there was need, there, so far as foresight could provide, assistance should be at hand, not only in the shape of skilled surgeons and nurses, but also in the shape of all the things essential to the success of their ministrations, such as stretchers, ambulances, food, clothing, and medicines. Gifted with an infinite power of contriving and persuading, eloquent in many languages, felicitously audacious whenever audacity seemed the road to success, scornful of red tape, oblivious of frontiers, and always on the best possible terms with "our friends the enemy," Sir JOHN FURLEY has been the good genius of modern warfare. It can be no matter for surprise that his precise status, his right to be in this or that particular galley at a given time, has been a puzzle to many *martinets* and to many politicians, or that the KING of ITALY should have given expression to his perplexity on the subject. "They tell me," said His Majesty, "that Mr. FURLEY is not in the medical profession and yet I hear him called sometimes doctor and sometimes professor and to-night he was announced as Professor Dr. FURLEY. I have seen him more than once on Red Cross missions and he was here at the International Medical Congress. In what capacity does he act?" Being told "doubtless as a philanthropist," His Majesty graciously recognised the character and, when bidding adieu to the guests, expressed his hope of seeing Sir JOHN FURLEY again before long, "toujours en philanthrope."

It is a curious reflection that some of the most considerable advances of medical science during the last half century have been due to the labours of the great French *savant* who was not himself a physician, and that some of the most considerable advances in the direction of rendering surgery accessible to the injured have been due to those of a practical organiser who is not himself a surgeon. In times of peace, the work of directing Red Cross organisations being temporarily in abeyance, Sir JOHN FURLEY has found ample employment for his energies as one of the most active members of the Order of St. John of Jerusalem in England, and in that capacity has taken a very considerable share in the construction of that network of ambulance service which now covers the whole of the British Empire, and by means of which thousands of people, more especially among those who are likely to be brought into contact with accidents, have been instructed in the proper methods of dealing with them at the moment and on the spot. At every railway station men are now to be found who have been taught how to handle an injured person, how to lift and to carry him, how to extemporise a splint which may prevent a simple fracture from becoming a compound one, how to arrest hæmorrhage, and, in short, how to deal with almost any description of injury in a way to prevent it from being aggravated by roughness or want of skill. All this is due to the operations of the Order, and Sir JOHN FURLEY has not only promoted these operations as an active member of many important committees, but he has also been distinguished as an inventor of ambulances and cognate apparatus. His long experience has shown him exactly what is likely to be required and his mechanical skill and ingenuity have supplied contrivances which do not seem likely to be superseded. Perhaps his last achievement of this kind was the designing and superintending the construction of the South African hospital train, which consisted of seven bogie carriages, each about 36 feet in length and eight feet in width, the passage through the centre being continuous; four of these carriages were constructed to carry 72 invalids and 16 orderlies, whilst the others were arranged for two medical officers, two sisters and other members of the staff, a dining room, dispensary, linen closet, kitchen, pantry, and store room. This train was despatched to Ladysmith as soon as the siege was raised and at once took up 54 invalid soldiers with whom it reached Durban on the following morning and transferred them to the hospital ship *German*. The cases taken were the worst that could be selected at Ladysmith and Intombi, and it was not thought possible that all of them could survive the journey of 19 hours. During the 18 months in which the Red Cross Committee was responsible for it, this train made 108 journeys and travelled 42,115 miles. In the first six months the journeys were entirely in Natal but they were gradually extended until they touched Johannesburg and Pretoria. From this point journeys were also made to Komati Poort and once to Cape Town and back. In all, 321 officers, 19 nursing sisters, and 7208 non-commissioned officers and men were carried as patients; and only three of the soldiers and three members of the staff of the train died on the road.

Perhaps the most generally interesting part of Sir JOHN FURLEY'S book is the account which he gives of the siege of Paris by the Germans and of the subsequent outbreak of the Commune with its ghastly history of murder and incendiarism. During these events he seems to have borne a charmed life, and although he was constantly exposed to fire there is no mention of his having sustained a scratch. Every line bears unconscious testimony to his powers of fraternisation, even with the most unlikely people, and the reader obtains many glimpses of a queer society of soldiers of fortune, pressmen, and warlike amateurs of every description, as well as of men holding high command on both sides of every conflict that is described. Of an invitation to smoke and to drink beer with Prince BISMARCK Sir JOHN FURLEY records that he *cautiously* availed himself, and he seems to have gone in and out at Versailles very much according to his pleasure. Another narrative to be noted is that in which he describes his success in liberating a young Irishman named O'DONOVAN, a press correspondent, who was arrested by the Carlists in 1873 on suspicion of a design to poison DON CARLOS, and who had been more than six months in prison, and in daily imminent danger of being shot, when Sir JOHN FURLEY heard of his sad plight. The English Government was unable to intervene diplomatically, as to do so would have been a recognition of the Government of the Junta. In these circumstances, Sir JOHN FURLEY put his head into the lion's mouth, and not only withdrew it safely but succeeded in releasing his fellow countryman and in conveying him over the frontier into France. The episode forms an introduction to a singularly graphic and picturesque account of the battle of Estella, in which, after three days' continuous fighting, the hardy Basque mountaineers totally defeated a force very superior to their own. In a word, it may be said that Sir JOHN FURLEY'S "philanthropy" has taken him into well-nigh every country, during the last 40 years, in which fighting has been carried on, always with the object of minimising the sufferings which it has occasioned. The narrative is a brilliant record of good work done for mankind, and the simple and straightforward style of the author is such as to command full credence for even the strangest parts of his most interesting narrative.

◆

The Medical Defence Union.

THE annual report recently issued by the Medical Defence Union demonstrates that that body is still in a flourishing condition. The balance-sheet must afford satisfaction to the members, for the sum securely invested proves the financial stability of the society. The legal expenses were high but this only shows that the council has done its utmost for those members who have appealed to it for advice and assistance. It is the just boast of the officials that no expense is spared to obtain the best legal aid possible in each individual case. This procedure is, of course, highly praiseworthy and likely to inspire confidence in the minds of the members. The solicitor's report affords much interesting material for study and reflection. No less than 182 cases were referred to him and completed within the year. Of this number, 61 were concerned with libel and slander against members of the union. In no single instance was a member attacked in this manner without, as a result of the action taken on his behalf, his professional good name and reputation being fully cleared. Viewed from a legal standpoint, there is, as the solicitor points out, probably no class of case in which the element of uncertainty in regard to result is more strongly marked than that of libel and slander. We think, therefore, that the union may feel justly and deservedly proud that of the 383 cases undertaken within the past nine years on behalf of its members in order to vindicate and to protect their professional honour and reputation, in three only have adverse verdicts been recorded. 31 of the 182 cases dealt with in the past year relate to actions for malpraxis which were defended on behalf of members. This is a class of charge which may be easily brought against a medical practitioner and may prove very costly to defend. Further, such actions are generally instituted by persons who have no means of their own and consequently are unable to pay any costs in which they may be mulcted.

Litigants, however, appear to have become impressed with the knowledge that, unless there is something actually tangible to go upon and their complaint has some foundation more substantial than that of mere lay opinion, it is an unwise expedient to bring an action against a medical practitioner who has at his back the powerful resources of the union. Consequently the number of cases under this particular heading shows a decrease rather than an increase as years go by.

The work of the union does not lie, however, entirely in individual defence of its members, but collective defence also claims the attention of the council. Every endeavour is made to suppress unqualified practice and several cases of this nature have been undertaken with success during the past year. A number of cases of impersonation have also been dealt with. The thanks of the whole profession are due to the union for these efforts to detect and to punish, as far as the unsatisfactory state of the law will permit, those individuals who attempt to deceive the public. We have on several occasions commented on the value to medical practitioners of the various defence associations which are now in existence. To whichever branch of the profession a practitioner may belong he is never free from the possibility of attack by unscrupulous or deluded individuals in matters which seriously affect his reputation. If he attempts to fight such an action alone he will not improbably find himself in a very serious position. The secretaries and the solicitors of the defence societies, owing to their great experience, have become specialists in such matters and we therefore once again strongly advise our readers to become members of one or another of these most useful societies.

Annotations.

"Ne quid nimis."

THE VISIT OF THE CHANNEL FLEET TO EDINBURGH: AN INTERCHANGE OF MEDICAL COURTESIES.

IT was particularly appropriate that the medical men of Edinburgh should take the opportunity afforded by the visit of the Channel Fleet to entertain in the most cordial manner the medical officers accompanying the fleet, for Scotland has been the place of birth or the place of education of many surgeons who have held with honour to themselves and to their profession positions in the medical service of the Royal Navy. Two names in particular may be singled out for mention—those of Dr. James Lind and Sir Gilbert Blane—for to them belongs the honour of first attempting to regulate the sanitary condition of the seaman's life, the particular object of their endeavours being the elimination of scurvy. To Blane is generally attributed the discovery that lemon-juice was useful in the treatment of scurvy, but, as a matter of fact, the remedy had been strongly recommended by Lind some years previously. Lind's treatise on scurvy was published in 1754, while it was not till 1780 that Blane published his small book, "On the Most Effectual Means for Preserving the Health of Seamen, particularly in the Royal Navy." Scurvy is, for practical purposes, almost a thing of the past, and on the whole the health of the sailor, whether in His Majesty's navy or in the mercantile marine, is now well cared for, but, none the less, modern shipbuilding and modern conditions of life have introduced new problems of sanitation which require close attention from the medical man. The "*ship's doctor*" of the future will have to be a thoroughly well-educated physician, surgeon, and sanitarian, and must use every opportunity that he can obtain to exchange views with his colleagues on shore. For this reason the interchange of courtesies between the medical officers of the Channel Fleet and the medical men of Edinburgh is particularly interesting and we congratulate those concerned in bringing it about. On May 22nd Mr. H. Alexis Thomson gave a demonstration to the medical officers of the Channel Fleet of recent methods in the treatment of venereal disease and exhibited slides showing the pathology and bacteriology of venereal lesions, afterwards conducting the party through the installation of Turkish and other baths in the Royal Infirmary and the new gynæcological theatre. Later the Royal College of Physicians entertained the visitors at luncheon, the President, Dr. J. Playfair, being in the chair. On May 23rd Dr. Claude B. Ker took a party over the New City Hospital for Infectious Diseases before lunch, after which he escorted them to Craig House, where they were received by Dr. T. S. Clouston and shown over the splendid building for the treatment of the insane and over the East House after tea, when Dr. W. Ford Robertson gave a most instructive demonstration of the microscopic pathology and bacteriology of general paralysis of the insane. On May 24th Dr. George Mackay gave a demonstration of external diseases of the eye and the use of the electro-magnet and other instruments. The guests then lunched with the infirmary surgeons and were later conducted over the Macewen Hall. On May 29th the medical officers of the fleet gave a luncheon to their entertainers. This was rendered possible by the generosity of the ward-room officers of the flagship, H.M.S. *Exmouth*, who lent their ward-room for the purpose to the medical officers of the fleet. The guests were afterwards conducted round the ship, the turrets, and torpedo room, and were greatly interested. On May 30th Mr. Harold J. Stiles gave a surgical demonstration in the Sick Children's Hospital, thus ending an interesting series. The significance of an occasion that was thoroughly pleasant to all concerned lies in the fact that here we have a definite and successful attempt on the part of the medical officers of the navy to get into touch with their civil colleagues. The medical officers of the services have in the past been isolated even more than their particular circumstances warrant from all professional relations, and this situation has had unfortunate results. But into these services, under improved regulations, we are now seeing a very good grade of officer pass and it seems to us of real importance that whenever an opportunity arises of renewing social and scientific relations with their civilian brethren full advantage should be taken of it.

THE CENTRAL MIDWIVES BOARD AND THE BELFAST MATERNITY HOSPITAL.

THE Central Midwives Board was established for the purpose of preventing incompetent and uninstructed women from undertaking obstetric work but in connexion with the operations of the Board in the North of Ireland an unfortunate misunderstanding has arisen which, if not corrected, will disqualify many midwives of the very class which the Board was intended to uphold and to encourage. The nurses in question were trained at the Belfast Maternity Hospital, an institution which has existed for more than a century, is a well-known school of midwifery, and is officially recognised as such by the Central Midwives Board. These facts notwithstanding, the Board *has seen fit to* take up a position which is suggestive of comedy rather than of administrative earnestness by refusing to place on the roll of certified midwives the pupils who had been trained at that hospital previously to April 1st, 1905. No reason for this singular decision was at first assigned but it has since become known that the nurses were to suffer because a certain application from the Belfast Maternity Hospital was too late in arriving. To this the hospital authorities have replied that the new Maternity Hospital—the largest in Ireland outside Dublin—was not ready for occupation until the end of 1904, that they had informed the Central Midwives Board as to the position of affairs more than a month previously, and had received an assurance that the subject would be considered when the new buildings were ready. The irony of the situation is heightened by the fact that "women in *bonâ fide* practice" a few years ago may be admitted to the roll while these Belfast nurses who have been carefully trained and have passed an examination are excluded. When legislation on the subject of midwives was in progress it could hardly have been the intention of Parliament to bring about such an anomaly as this, and we trust that it will be possible to find a means both of satisfying the requirements of the Central Midwives Board and of avoiding an obvious injustice to the Belfast nurses.

THE ANALYSIS OF RAIN AND THE PUBLIC HEALTH.

THE abundant fall of rain this week has to some extent allayed a very real anxiety which was being felt as to the shortage of water-supply. The condition of the country was perilously near a serious drought, and when a drought occurs so early in the year and at a time just preceding the summer months, which in normal times are dry, the outlook cannot be said to be assuring. But it is often overlooked that rain has another very important function besides that of supplying water for the field, the stream, and the reservoir. is a very powerful purifier of the air and its cleansing effect is very marked on the atmosphere of cities and towns and manufacturing districts. In fact, the sanitary condition of the air of a given place may be fairly gauged by chemically examining the falling rain for impurities. The quantity of impurities so scavenged is in many instances as remarkable as it is variable. In other words, what may be called the sewage of the air varies in kind and amount in accordance with the number and kind of agencies which are at work polluting the air. An analysis of rain, therefore, conducted at intervals is calculated to afford valuable knowledge of the sanitary condition of a place and it seems to us that no meteorological observations in connexion with their bearing on the public health can be regarded as complete unless in addition to recording the rainfall they record also the analysis of rain as regards impurities. Instances are not wanting to illustrate the valuable indications given, from a point of view of health, by an analysis of rain. Thus the rain falling in Manchester has been found to contain 7 parts per 1,000,000 of free ammonia, 0·3 part of organic ammonia, 47 parts of sulphuric acid (sulphates), and 5·88 parts of hydrochloric acid (chlorides). London has similarly shown 3·4 parts of free ammonia, 0·2 part of organic ammonia, 20 parts of sulphuric acid (sulphates), and 1·25 parts of hydrochloric acid (chlorides). Inland rain, on the other hand, has given the following results: free ammonia, 1 part per 1,000,000; organic ammonia, 0·10 part; sulphuric acid (sulphates), 5·52 parts; and hydrochloric acid (chlorides), 3·99 parts; while the rain collected on the sea coast gave the following: free ammonia, 1·90 parts; organic ammonia, 0·40 part; sulphuric acid (sulphates), 5·88 parts; and hydrochloric acid (chlorides), 56·15 parts. The figures suffice to show the value of this method of investigation and it is interesting to note that according to these results country air contains less impurities than sea air though they are augmented in the latter case by the salt of the sea. The method, too, would give valuable results, we think, in connexion with the attempts to mitigate the smoke nuisance. The impurities of the air which are washed out by the rain would obviously bear a direct relation to the number of chimneys which are polluting the air with filthy smoke. An abatement of smoke, therefore, would be indicated probably by a diminution of the amount of impurity in the rain. We commend the suggestion to that useful institution, the Coal Smoke Abatement Society, which by adopting a system of periodically submitting rain to analysis might obtain direct evidence as to the success or failure of its efforts. We should, at all events, like to see the meteorological observations throughout the country in regard to quantity of rain supplemented by a column recording its quality also.

THE DANGERS OF CIRCUMCISION AS PERFORMED AMONG JEWS OF THE POORER CLASS.

AT the Stepney coroner's court Mr. Wynne Baxter held recently an inquest upon the infant son of a tailor of the Jewish faith in which the jury returned a verdict of "Death from hæmorrhage after circumcision," adding to this that it was due to misadventure. Before their conclusion was arrived at, however, the coroner had had a good deal to say to the mohel who had performed the rite as to the acts and omissions which had preceded the fatal result and had received from him replies that were not altogether satisfactory. The mohel, a Mr. Baum, had circumcised the child and an hour later had seen that the dressing had come off and had replaced it, and again afterwards, finding that hæmorrhage had recommenced, had taken steps to stop it but had not succeeded. He had then recommended that a medical man should be summoned and after some delay, on account of the gentleman first called upon being absent, a medical man had seen the child. Eventually before the child died three medical practitioners had endeavoured to stop the bleeding and to save his life, and the first of these was blamed by the coroner for not having realised the serious nature of the case when first he saw it. Some discussion took place as to the precise nature of the symptoms, and as to the causes which led to them, but the general facts upon which the coroner founded his observations were not peculiar to the particular case before him but were such as may be found arising at any time after circumcision not performed by a medical man, and similar conditions may on any occasion constitute a source of danger to life. Mr. D. A. McCombie, who with his partner, Mr. G. Michael, had been summoned when the child was in too serious a condition for them to be able to save his life, summed the matter up in his evidence by saying that "the case was rather out of the ordinary and the mohel, in his opinion, had failed to recognise fully the fact." The coroner further elicited the intelligence from Mr. Baum that he did not belong to the Initiation Society formed to teach followers of his calling their business. He also drew from him the retort that the members of the society were all young men and that he was an expert mohel. He had stated earlier that he had practised for more than 20 years. This throws light upon his attitude and upon the question of delay, and in these circumstances the coroner's observation was well founded that "mohelim are like midwives and liable to get into trouble if they do not bring proper skill to bear." The operation of circumcision when performed by a layman who has been partially instructed or has had some experience in its performance bears this resemblance to the delivery of a pregnant woman by a midwife that it may be performed in a considerable number of cases, if not without danger, at any rate without any untoward result calling public attention to the underlying risks. When, however, anything out of the usual course occurs the attendance of a medical man becomes necessary at once and if the unusual symptom escapes notice or if its serious nature is either not recognised or disregarded the absence of timely medical aid is likely to be followed by fatal consequences. It may not necessarily be that the mohel or the midwife is unwilling to ask for the assistance of a medical man owing to a feeling of false pride or of self-sufficiency. It may simply be that from want of actual experience of the kind of danger which has arisen and from absence of such knowledge as medical training, even without actual experience, may impart, he or she may fail to recognise at an early stage the existence of conditions which would claim at once the attention of a medical practitioner. Later the fact that danger is there may be observed but it may then be too late and the obtaining of a medical man's attendance at such a juncture may not be easy. On many occasions, however, apart from ignorance, there will be the risk that the half-trained person, relying upon himself or herself, may resent the implication of want of skill and not only may not suggest the calling in of medical assistance but may actually resist it when it is suggested by others. The coroner in the case under comment did not have this fault to find. Indeed, he called attention to the fact that the mohel had asked that a medical man should be called in, although he had done so later than he should have done. Mr. Wynne Baxter intimated that but for this he should have directed the jury to return a verdict against him of manslaughter.

LIQUOZONE IN THE CORONER'S COURTS.

AT the Stoke Newington coroner's court Dr. W. Wynn Westcott on June 5th held an adjourned inquest upon two children who died after taking daily doses of liquozone. One case was briefly referred to in THE LANCET of June 3rd, p. 1538. Since then Dr. H. R. Oswald has held an inquest at the Rotherhithe coroner's court upon a woman who had been taking liquozone; he adjourned the inquiry for further toxicological evidence. The main facts of the Stoke Newington cases are as follows. Mr. S , having obtained a free sample bottle of liquozone on May 17th, proceeded to take some himself for the relief of hæmorrhoids and to give some to his wife to relieve her neuralgia; success followed in neither case. The directions covering the sample did not specifically advise its use as a vermicide, but Mrs. S. proceeded to dose her two little girls with half an ordinary teaspoonful of liquozone appropriately diluted and given once daily before breakfast; she believed that her daughters suffered from worms but they were otherwise in very good health; Mrs. S. informed Dr. Wynn Westcott that she considered "germs meant worms." It is apparently common for those who take liquozone to complain of subsequent nausea and "pain in the stomach," the proprietors considering this a proof of its desired activity. There are no explicit directions as to what dosage children should receive: adults are told to take a teaspoonful in water, "for children it must be proportionately diminished." The elder child, aged nearly four years, became ill on May 21st, and when seen by Mr. T. W. M. Harneis on the 22nd she was delirious and collapsed and had had vomiting and diarrhœa; she died from exhaustion on the 23rd. The ounger child, aged two years, was attacked with similar ptoms on the 22nd and died on the 26th. The ner instructed Dr. F. J. Smith to conduct both psies. Dr. Smith found all the viscera of the en healthy and normal except for a small patch in cous membrane of the stomach of the elder girl tive of the effect of an irritant poison.

Dr. J. R. Wallace gave evidence as permanent medical adviser to the British Liquozone Company; he had often taken liquozone without ill-effects but he had never analysed its contents; he doubted if an overdose could be taken, but he excepted babies from this statement Mr. Avory, K.C., and Mr. C. Matthews are appearing for the company. Dr. Wynn Westcott again adjourned the inquest until a report could be furnished by Sir Thomas Stevenson on behalf of the Home Office as to the nature and the probable effects of the administration of liquozone in these cases.

RECOVERY FROM TUBERCULOUS MENINGITIS.

THE possibility of recovery from tuberculous meningitis is denied by many writers, though cases have been recorded in which a patient recovered from what appeared to be an attack of tuberculous meningitis and succumbed to a second, the necropsy showing signs of both recent and old meningitis. In other cases the diagnosis of tuberculous meningitis was borne out by the presence of tubercles in the choroid. The recent operation of lumbar puncture has furnished still stronger proof of the possibility of such recovery. At the meeting of the Société Médicale des Hôpitaux de Paris on May 12th M. Paul Claisse and M. Abrami reported the following case. A man, aged 30 years, was admitted into hospital on March 11th, 1905. He had been in good health until the beginning of the month, when, without apparent cause except overwork, he became weak and the least effort caused fatigue, appetite was lost, memory was impaired, and he suffered from slight but continuous frontal and temporal headache. He slept badly and awoke in the night covered with perspiration. His condition became worse and he lost flesh considerably. The temperature was 100·4° F. and the tongue was furred but moist. Examination of the patient was negative. On March 13th there were temporary delirium, marked retraction and sensitiveness of the abdomen, alternate dilatation and contraction of the pupils (*instabilité pupillaire*), and "paradoxical reflex" (contraction of the pupils in the shade and dilatation on exposure to light). There were no other signs of meningitis, such as rigidity of the neck, Kernig's sign, or modification of the reflexes. Lumbar puncture was performed and 12 cubic centimetres of clear fluid flowed out in a jet. It contained a good deal of albumin and fibrin and an abundance of lymphocytes. Tubercle bacilli were not found in the fluid but two guinea-pigs inoculated with it developed tuberculosis. The patient became drowsy and refused food and when questioned manifested delusions of persecution. On the 14th he became violent, his neck was a little rigid, and the meningeal tâche was obtained. The temperature was 100·2° and he was constipated. The abdomen was always retracted and sensitive. On the 15th there was slight inequality of the pupils. On the 16th there was a tendency to a cataleptoid state and he preserved for a long time whatever position his limbs were placed in. On the 17th he showed some improvement; he answered questions and did not complain of his head but he was still delirious at times. A second lumbar puncture was performed. The liquid removed amounted to 15 cubic centimetres and was clear. It contained less albumin and fibrin and fewer lymphocytes than that removed before. The improvement continued and complete recovery followed. On April 4th a third lumbar puncture was performed and the fluid obtained was perfectly normal. In this case there was a striking parallelism between the improvement in the symptoms and the condition of the cerebro-spinal fluid. The diagnosis of the tuberculous nature of the meningitis was based upon the symptoms, the cytology of the cerebro-spinal fluid, and the inoculation experiments. The symptoms exactly corresponded to those of the delirious form of tuberculous meningitis, which is well known in adults. One of its characteristics is the absence of severe meningeal symptoms, such as vomiting and Kernig's sign, as exemplified in this case. The cerebro-spinal fluid had the usual characters found in tuberculous meningitis—an albuminous and fibrinous liquid containing an abundance of lymphocytes. As to the non-success in finding the bacillus tuberculosis in the fluid, many writers have encountered a considerable number of failures. Thus Pfaudler could find the bacillus only in 33 per cent. of cases in the early stage of tuberculous meningitis and in 75 per cent. in the last days of the illness. All these cases were fatal, therefore it is not astonishing that the bacillus could not be found in a case of recovery.

THE COLONIAL NURSING ASSOCIATION.

THIS association was established for providing trained hospital and private nurses for the British colonies and dependencies and other British communities abroad nine years ago and the report for the year ending April, 1905, shows that there has been a steady and increasing demand for nurses. Since April, 1904, more than 50 new candidates have been added to the roll of the association. Of the 121 nurses employed during the year 94 have been in Government service and 27 have acted as private nurses. Last year 109 nurses were employed, 81 by the Government and 28 by private persons. The special demand for nurses possessing a midwifery training has caused the committee of the association to impress upon nurses contemplating service abroad the importance of possessing *the certificate of the Central Midwives Board* and many of the candidates have been registered under the new Act. The work of the association is hampered by want of funds; its aims—to establish trained nurses in all British communities beyond the sea—cannot be persevered with unless the public subscribe more liberally than they have done hitherto. The address of the association is the Imperial Institute, S.W.

THE DESIRABILITY OF A STANDARD EYE DROPPER.

THE wide variation in size of the droppers used in ophthalmic work is the subject of contributions in the *American Journal of Pharmacy* for March, p. 125, by Dr. P. N. K. Schwenk, Dr. Wendell Reber, and Mr. M. J. Wilbert. Since the majority of eye drops contain alkaloids or their salts it is important that a correct dosage should be obtained. The administration of too large a quantity of these potent medicaments may produce undesirable results. The excess finds its way with the tears through the canaliculi into the nose and thence into the highly absorbent mucous membranes of the upper air passages, where it is absorbed into the circulatory system. It is usually considered by ophthalmic surgeons that one minim is the unit of measure and that one drop is its equivalent. The strengths of solutions are regulated accordingly, but owing to the wide variations in the eye droppers that are employed corresponding variations are found in the size of drops as delivered into the eye. Dr. Schwenk suggests the employment of a straight dropper with a tip 2·0 to 3·5 millimetres in diameter; a tube of this size should deliver 60 drops of an aqueous solution to the drachm, allowing an inclination of the dropper of 45° to the horizon. The size of a drop bears a direct ratio to the surface from which it is delivered, so that in a curved dropper the solution follows the curve to the point of rest and produces a larger drop than if delivered from a point. The same is true of beaded droppers. Dr. Reber points out that the standard dropper delivers drops of different size with different liquids varying with the specific gravity and other physical characters of the liquids employed. To avoid an excess of a solution finding its way into the circulatory system he cautions patients to press a soft handkerchief over the inner corners of both eyes near the tops of the tear ducts. He considers that owing to the great power of absorption of the mucous membrane of the nose the entrance of one-hundredth of a grain of an alkaloid into the circulatory system in this way would be equal to the entrance of one fiftieth of a grain by the stomach. Mr. Wilbert describes a form of eye dropper as used in Germany which partially overcomes this difficulty. It consists of a small vial having a perforated stopper through which is introduced a corrugated or twisted glass rod which forms the dropper. The advantages of this device are that the glass rod does not hold more than two or at the most three drops at a time, that the drops form and disengage slowly, and are in addition but slightly affected by any unavoidable tremor. This discussion is useful and emphasises the need that exists for uniformity of construction in vessels employed for delivering eye drops. As aqueous solutions are almost invariably employed it should not be difficult to obtain vessels of a given size and standardised to deliver drops of distilled water slowly of such a volume that 60 drops should measure one fluid drachm.

MUNICIPAL MILK-SUPPLY.

IN an annotation in THE LANCET of April 1st, p. 873, we very briefly referred to the methods adopted by the municipality of the city of Rochester, U.S.A., in regard to the supply of milk. The plan there adopted was mentioned by Dr. G. F. Cleary in a paper which he read at a meeting of the Royal Sanitary Institute on March 25th as an example not merely of the success of a hygienic principle but of practical operation also. Under the supervision of Dr. G. W. Goler every precaution is taken at the Rochester depôt to sterilise not the milk but everything with which it comes into contact.

A central station at which the milk is prepared is organised each [illegible] trained nurse and assistants [illegible] ottles, &c., and where all of [illegible] nilk laboratory. Everything coming in contact with the milk is thoroughly sterilised in steam sterilisers. The milk itself is not subject to any pasteurising or [illegible] are only an open [illegible] the production and [illegible] m the milk is taken [illegible] which are carried to [illegible] per cubic centimetre.

We now learn that the cost of distributing the milk and, what is far better and more important, of spreading abroad some knowledge of the care and feeding of infants has averaged less than £180 per annum. It is a pity therefore that any hesitation to carry out the supply of milk on strictly hygienic principles is shown, for, as a matter of fact, the cost, whether maintained by public or private enterprise, need not be great and in any case the results are calculated to afford a very ample compensation in the prevention of infant mortality.

ANTIDOTES TO NICOTINE.

IN a note recently brought before the Académie des Sciences[1] M. O. Zalackas compares the action of strychnine, eserine, and the cruciferous plant Nasturtium officinale as antidotes to nicotine. He finds from experiments on rabbits in particular that there is no antagonism between strychnine and nicotine. With eserine the antagonism is more marked.

---

[1] Comptes Rendus, March, 1905, p. 471.

A non-toxic dose of nicotine neutralises a toxic dose of eserine, provided that the nicotine is administered before the eserine. In the case of the rabbit the same result was obtained when the order of administering the injections was reversed. But a toxic dose of nicotine does not at all neutralise a toxic dose of eserine, though the neutralisation is apparent owing to the effects of the eserine being masked by the nicotine. It is a curious fact, as Martin Damourette has shown, that nicotine possesses both stimulating and paralysing properties. Now, it sometimes happens that the paralysing effects, which probably form a small part of the properties of eserine, are added to the paralysing effects which form a large part of the effects of nicotine, so that the drugs tend to exert the same action. M. Zalackas considers Nasturtium officinale to be a most useful antidote to nicotine. This plant is rich in nitrogen, iodine, and iron; when it grows in soils containing the two last-named elements it is especially rich in them. The fresh plant is bruised in a mortar and the juice is then expressed and filtered. He describes in detail an experiment on a rabbit. A toxic dose of nicotine (0·025 gramme) was injected into the jugular vein of a rabbit and in the course of a minute the symptoms of poisoning by nicotine supervened. Just when asphyxia appeared to be imminent a Pravas syringeful of the juice, containing 0·3 gramme of caffeine, was similarly injected. After ten minutes diuresis set in, the urine smelling strongly of tobacco. After an hour half a syringeful of the same liquid was administered. As a result the urine was copiously excreted, the convulsions gradually diminished in intensity and frequency, the respiration and circulation became normal, and sensibility returned. The restoration to health was, however, accompanied by a pronounced salivation. Experiments with dogs gave equally satisfactory results, so that M. Zalackas claims Nasturtium officinale to be *par excellence* the antidote to nicotine.

CEREBRO-SPINAL RHINORRHŒA WITH RETINAL CHANGES.

IN 1899 Dr. StClair Thomson published a monograph on cerebro-spinal rhinorrhœa containing an account of one case observed by himself and of 20 others which he had been able to collect from medical literature. The condition is so rare as to render every case important. In the *American Journal of the Medical Sciences* for May Dr. S. I. Schwab and Dr. J. Green have recorded a case in which retinal changes were present. In eight of the collected cases optic neuritis or atrophy was observed and in five of these vision was reduced to perception of light or completely lost. A woman, aged 32 years, complained of a continuous watery discharge from the right nostril. Examination showed nothing abnormal in the throat or the nose. The discharge began two years before and was continuous both by night and by day. The quantity varied from a few drops to three or four cubic centimetres per hour. When the patient was worried or fatigued the quantity increased. The fluid was clear and tasteless and did not stiffen or stain the handkerchief. When the head was inclined the flow increased. There were occasional headaches which were not influenced by the amount of the discharge. The patient was neurotic and there were increased knee-jerks, anæsthesia of the pharynx, hyperæsthesia in the small of the back, and tremors of the hand. The fluid was of specific gravity 1010 and did not contain albumin or mucin. On centrifugalisation it yielded a few leucocytes. It reduced Fehling's solution. The right optic disc was pale and its inner margin was blurred. The veins were full and slightly tortuous; the arteries were narrow. The left disc was blanched and the vessels were contracted. Four years before the discharge from the nose began the patient noticed haziness of vision and consulted an ophthalmic surgeon who noted: "Neuro-retinitis; swelling 3 D. in the right disc; left disc beginning to atrophy." That the fluid which escaped was cerebro-spinal did not admit of any doubt. Dr. Halliburton, who examined the fluid in Dr. StClair Thomson's case, says: "The diagnosis of cerebro-spinal fluid from other forms of watery flux from the nose need not in future present any difficulty. The constant and long-continued escape from the nostril of a perfectly clear watery fluid should always arouse suspicion as to its subarachnoid origin. When this fluid is found to be free from taste, smell, and sediment, when albumin and mucin are found to be practically absent, and when Fehling's solution is reduced by it, the suspicion becomes a certainty." Little is known as to the etiology of this curious affection. Whether it is due to some inflammatory process or to anatomical defects in the skull are undecided questions. The presence of ocular changes are of great importance because they point to some more general process. In the case recorded above it is noteworthy that the optic neuritis was observed four years before the discharge of fluid from the nose.

THE adjourned annual meeting of the Medico-Psychological Association of Great Britain and Ireland, held on May 18th, was further adjourned to July 19th, in order to receive the report of the statistics committee, and this adjourned meeting will commence at 10.30 A.M. at the rooms of the association, 11, Chandos-street, Cavendish-square, London, W. The Council of the association has fixed July 20th and 21st for the annual meeting, under the presidency of Dr. T. Outterson Wood, at the rooms of the association as above. The honorary secretary will be glad to receive the titles of any papers which members may desire to read at the meeting.

ON Wednesday evening, June 14th, Sir Richard Douglas Powell, President of the Royal College of Physicians of London, will deliver the Bolingbroke Lecture at the Bolingbroke Hospital, Wandsworth, at 8.45. The South-West London Medical Society which is responsible for the arrangements with reference to the Bolingbroke Lecture, extends a cordial invitation to all members of the medical profession to be present on the occasion. The subject of the lecture will be Some Clinical Lessons from the History of Medicine in the Last Half Century.

THE medical officer of health of Cape Colony states that for the week ending May 13th the condition of the colony as regards plague was as follows. At East London eight cases and at Queenstown one case were discovered during the week, all the patients being natives. Plague-infected rodents were found at Port Elizabeth, Uitenhage, East London, and King William's Town. In the other districts of the colony no case of plague in man or the lower animals was found.

WE regret to announce the death of Mr. Frederick James Gant F.R.C.S., which took place on Tuesday last, June 6th, at his house, 16, Connaught-square, London, W. Mr. Gant, who was for over 50 years connected with the Royal Free Hospital, was the author of a "Manual of the Practice of Surgery," which in its day had considerable popularity among students.

AT a meeting of the council of the Medical Defence Union held on June 1st Dr. W. A. Elliston, ex-President of the British Medical Association, was elected President of the Union, *vice* Mr. M. A. Messiter, resigned.

MR. W. Bruce Clarke, surgeon to St. Bartholomew's Hospital, will be a candidate for a seat on the Council of the Royal College of Surgeons of England at the approaching election.

SANITATION AND THE PANAMA CANAL

THE SOLUTION OF CERTAIN CLIMATIC AND HYGIENIC PROBLEMS

BY JOHN GEORGE LEIGH

II [1]

THE most prominent and noteworthy characteristic of the climate of the Isthmus of Panama, as compared with that of more temperate regions, is the remarkable uniformity of temperature throughout the year This is well illustrated in Table I, compiled from information collected by the United States Weather Bureau Among the elements which determine this uniformity may be mentioned the direct heat received from the sun, the proximity of the two oceans, the fact that the winds blow across the country almost unobstructed by hills or jungle, and the influence of the excessive volume of aqueous vapour held in suspension in the atmosphere Under the tropical sun the evaporation from the oceans is abnormally rapid and consequently the ill *effects of the* high temperature are accentuated by a humidity extremely debilitating to those bred in or accustomed to, a temperate climate Thus, quite irrespectively of endemic diseases and the abominable sanitary conditions which have heretofore prevailed, not only in the small native settlements but also in the cities of Panama and Colon the Isthmian climate has physiological effects demanding unceasing vigilance on the part of those subjected to it

TABLE I —*The Climate of the Isthmus of Panama compared with that of other Localities*

Localities	Approximate latitude	Years of observation	Average temperature				Maximum recorded

Manila	15	17	80 0	84 0	77 0	7 0	100

Since the period of the Spanish conquest many unprofitable attempts have been made to colonise the country, but the only foreigners who have been able to withstand the climate with any measure of success have been people of Iberian extraction inured from their birth to a tropical environment, the Caribbean negroes employed by the French canal companies who have remained in the Isthmus and a few Chinamen who have become permanent residents *These races have become so strangely* mingled that it is often possible to trace in the face of a single individual the features or racial characteristics of the three peoples, plus those of the native Indian

Near the sea and along the greater part of the line of the projected canal, much of the land is low lying swamp, the washings of the soil full of vegetable remains brought down by the rivers in their flood For miles round the country reeks with exhalations from decomposing organic matter, and the deleterious effects of these emanations con[illegible] of specific diseases but as un[illegible] on all sides All the physio[illegible] the tropics are here found in exaggerated forms The abnormal moisture of the atmosphere lessens evaporation from the skin and lungs, and this condition in alliance with the continuous heat, readily induces languor, loss of appetite, depression of spirits and dulness of the entire nervous system, with consequent reduction of the pulse rate, decrease in respiratory action, poverty of the blood softness of the tissues, disorders of the kidney, stomach and intestines, and a tendency towards congestion of the liver and spleen Fevers—malarial, bilious, and congestive—are responsible for a large proportion, possibly four fifths of the sickness incidental to the climate Foreigners seldom, if ever, acquire the same comparative immunity from local diseases as is enjoyed by the natives, they are always subject to febrile disorders, and in the intervals between the attacks suffer from the depressing and debilitating symptoms already described The most trying period is probably September and the two following months, during which dysentery is common and frequently accompanied by a type of bilious fever closely approaching in malignity and fatality the much dreaded ' yellow Jack

Nowhere in the world is the close affinity between marshy districts and certain diseases more clearly demonstrated, nor can it be denied after the experience gained in the construction of the Panama railroad, and especially in connexion with the excavation of the canal traversing the same region, that the morbific effects of marsh miasmata are largely increased by the disturbance of the surface soil and, on the other hand may be considerably lessened as the excavators reach strata more free from organic matter in decomposition The extent to which miasmata may spread over land is a complicated and not always easily determined question inasmuch as it appears largely to depend upon local conditions For instance the presence or removal of trees has a remarkable effect in intercepting or diffusing the noxious gases and often particularly in Italy, it has been found that the destruction of a belt of wood adjacent to marshy land has been instrumental in introducing fever to a heretofore healthy district No such effect, however, appears to have followed the clearings along or near the canal route in the Isthmus of Panama The first stages of the work were executed in an atmosphere begirt by luxuriant vegetation gradually reduced as the operations extended until at last a passage was created for an unrestricted passage of air and as this work progressed the general hygienic conditions appear to have improved

Still it is as certain to day as ever it was that malarial fevers and other similar diseases are continually present in the Isthmus in aggravated forms, and that, pending the completion of the sanitary reforms already in progress or contemplated in and about the cities of Panama and Colon, yellow fever must always be considered endemic in the Canal Zone It is fortunate for the canal enterprise, whether regarded from the standpoint of the engineer or the economist that it *should now be under the control of* an administration which has had extensive and recent experience in dealing with kindred climatic and health problems The scourge of yellow fever may it is believed, be eliminated by the methods which proved so successful at Havana, and although it must be confessed certain disclosures concerning the management of affairs during the past 12 months are not altogether encouraging we may, I think, anticipate with considerable confidence an early realisation of this hope The effective control of malaria is by far the graver problem, especially during the period of canal construction, and it is quite within the bounds of probability that, should the measures adopted by the American authorities prove inoperative or be at any time relaxed, the mortality among the labourers on the Isthmus will be no less serious than it was in the days of the de Lesseps Company No one, it may be noted *has* expressed himself more emphatically on this point than Dr Gorgas

Thanks to the valuable records of observations and other data collected during the past 20 years under the auspices of the two French canal companies and the United States Government, it is possible to convey in comparatively brief space a very definite idea of the climate of the Canal Zone and its influences upon the progress of canal construction As foremost in the work of summarising these details and analysing them in such manner as to develop in the most convenient and convincing form the information which they convey, prominent mention should be made of General Henry L Abbot, one of the most eminent of American hydraulic engineers and long associated with Panama Canal studies To the latter I am much indebted for several of the figures and tables included in the present portion of this paper

The low latitude of the Isthmus of Panama brings the sun at the zenith twice during the year, once at noon on

---

[1] No I was published in THE LANCET of June 3rd 1905 p 1530

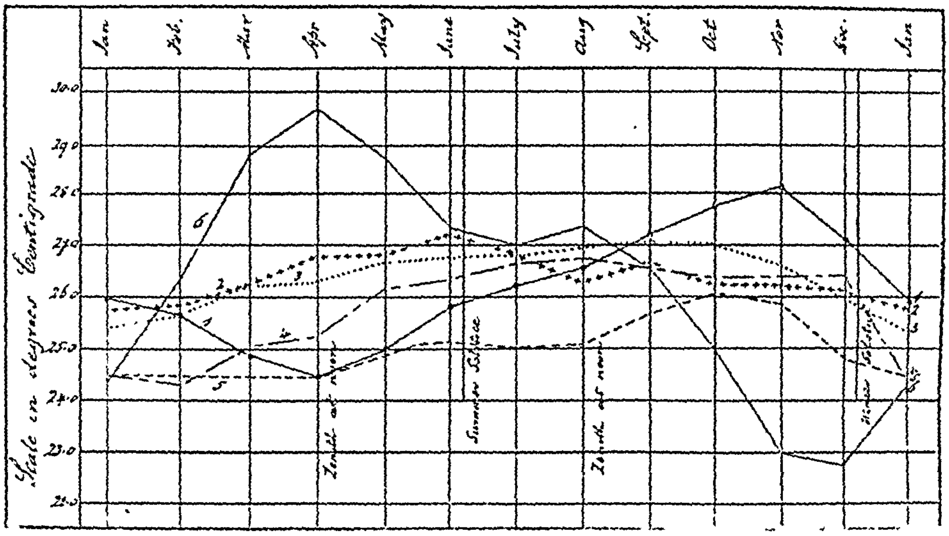
April 13th when it is journeying northward to reach its summer solstice on June 21st, and again on August 29th, when returning towards its winter solstice, which it reaches on Dec. 21st. The direct heat transmitted at these altitudes is then proportional to the sines of 90°, 75° 41′, and 57° 24′, or to the numbers 1·00, 0·97, and 0·84 for the zenith, the summer solstice, and the winter solstice respectively. It should, however, be noted, first, that the length of day, and hence the duration of solar radiation, attains its maximum in June and its minimum in December, and that this element consequently tends to reduce the natural fall of temperature during the sun's northward journey and, on the other hand, to augment it during the approach to its southern limit; and, secondly, that the temperature of the air as registered by the thermometer is affected by the modifying influence of the aqueous vapour held in suspension, which by day tends largely to reduce, and by night largely to increase, the temperature of the air at the earth's surface.

Another factor to be considered is the influence of the two oceans bordering the isthmus. In this connexion it may be of interest to remark that daily observations during several years of the temperature of the water at Colon and at Naos, Bay of Panama, have resulted in the following data:—Colon: annual average temperature, 79·3° F.; maximum, 81·9°, occurring in September; and minimum, 75·8°, in February. Naos: annual average, 76·1° F.; maximum, 80·0° (October); and minimum, 67·8° (February). The general movements of the atmosphere, which in large degree determine the influence of oceans upon neighbouring shore climates, are here governed by the locus of the ascending current of warm air following the sun in its travels north and south of the solstices. It must also be remembered that, while the great equatorial current of warm water entering the Caribbean Sea largely modifies the direct action of the sun upon its temperature, the Pacific on the other side, in the absence of such current, becomes a great natural thermometer to register the direct heat received, but with a retardation of about two months, both in maximum and minimum, representing the time required to influence the temperature of so large a volume of water.

The curves in Fig. 3 are an attempt to combine in diagrammatic and comparative form the several elements to which reference has been made. If the direct action of the sun as modified by humidity were alone considered there would be a range of monthly mean temperature of about 3·75° between the sun's first zenith transit in April and the middle of December. This, however, is reduced by the powerful joint influences of varying humidity, varying length of night, and of the two oceans to an observed range of 2·51° between June and January and a computed range of 1·64° between the sun's August transit of the zenith and January. The curves indicating the influence of the oceans show that the Atlantic is the more powerful, and this conclusion is confirmed by the remarkable identity of temperatures prevailing on the isthmus and along the northern coast of South America. But for the influence of the Atlantic the northern winds of the first four months of the year would sensibly aid the Pacific, then relatively cold, in moderating the temperature at Panama.

An analysis of the records of diurnal variations of temperature during a series of years, which have been made at a number of posts in the Isthmus, demonstrates that charac-

FIG. 3.



Absolute influence of different factors upon the monthly temperatures on the Isthmus of Panama. (1) the air during the night time; (2) of the observed temperature; (3) of the computed temperature; (Caribbean Sea; (5) of the temperature of the Bay of Panama; and (6) of humidity and sunshine by day.

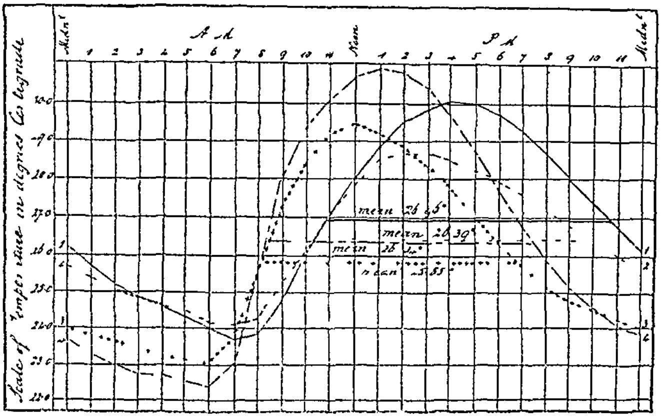
teristic differences exist only between the Caribbean coast, the interior, and the Pacific coast, and between the four dry months (January, February, March, and April) and the remaining eight months, when heavy rains prevail. These differences, recorded in Centigrade degrees, will be found exhibited in Table II. For greater convenience in later reference the Fahrenheit equivalents are given. It should be noted that these records—compiled from observations by the United States Weather Bureau—refer to the time of the seventy-fifth meridian (Bogota), and that consequently 19 minutes should be subtracted before comparison with observations based upon local time. This has been done in Fig. 4, which illustrates Table II.

FIG. 4.



Observed diurnal variations of temperature (local time) in the dry and wet seasons. (1) La Boca, dry season. (2) La Boca, rainy season. (3) Alhajuela, rainy season. (4) Alhajuela, dry season.

It will be seen that, as was shown in the case of the monthly averages, the changes of temperature from hour to hour and day to day are subject to far less variation on the Isthmus than in regions more remote from the equator. It should be remembered, however, that all compilations such as the above are based upon observations made where the thermometers were not exposed to direct solar radiation, and that, consequently, labourers exposed to the sun would experience much higher temperatures. As Alhajuela is about midway between the oceans it has been selected as a locality well suited to represent the climate of the interior of the isthmus. It is situated in the valley of the Upper Chagres, among the hills which here represent the mountain chain adjacent to the western littorals of North and South America and its altitude is but 150 feet above the sea. The temperature here at sunrise in the dry season is about 72° F., rising rapidly it reaches about 81° at 1 P.M., and then gradually falls to the minimum at sunset. During the rainy season, on the other hand, the temperature at sunrise is about 74° F., reaches a maximum of about 85° at noon, and then falls to about 80° at sunset and to the minimum at sunrise. At La Boca, on the Bay of Panama, the minimum temperature occurs later, at about an hour after sunrise, when it is 75° in both the dry and rainy seasons. The maximum, 86°, in the dry season is reached at 4 P.M. and 84° in the rainy season, at about 2.30 P.M. The fall is more gradual than in the centre of the isthmus, the mercury receding but little from the maximum point until after sunset. In short the changes of temperature on the Pacific coast are less decided and later than in the interior, though the daily average is about the same.

Of considerable importance, both in connexion with the study of isthmian climatic conditions and as bearing upon the construction of the canal, is the fact that the rainfall on the Caribbean side greatly exceeds that in the interior or on the Pacific slope, and is also much larger than that on the Caribbean coast of South America. Thus, during the period of the observations referred to above, the annual average rainfall was: at Colon, 130 inches; at Alhajuela, 103·8

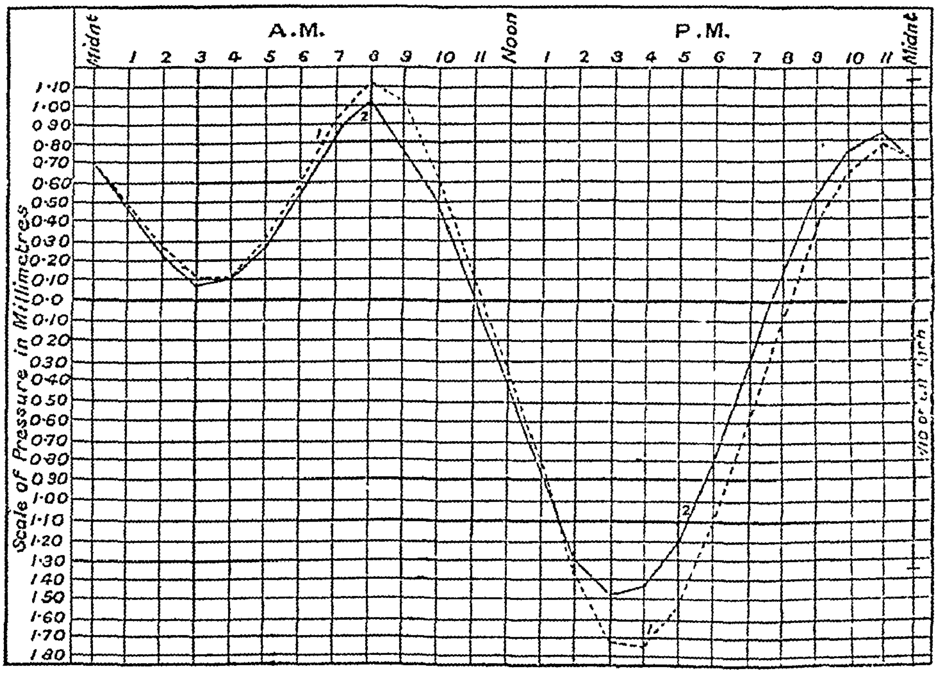
inches; at La Boca, 74·5 inches; at Barbados, 39·6 inches; at Trinidad, 56·5 inches; and at Curaçoa, but 16·1 inches. It is evident from Table III. that in each section of the isthmus there is a fairly well-defined dry season, that this comparative exemption from rain is more characteristic of the interior and Pacific coast than it is of the region adjacent to the Caribbean Sea, and that (after allowing for the so-called dry seasons) there may yet be expected in each of the sections an annual rainfall of respectively 85 to 104, 45 to 75, and 128 to 150 inches. High as these figures are they compare most favourably with the annual records of rainfall, averaging nearly 300 inches, at Greytown, the proposed Atlantic terminal of the once much-discussed Nicaragua Canal. It will clearly be no small advantage to the engineers of the Colon-Panama waterway to be able to depend upon several consecutive months of relative drought in which to lay cement and to prosecute other difficult work. Frequently during the rainy season the downpours are remarkable, even for the tropics, and a few hours suffice to transform trickling streams into foaming torrents. Particularly is this the case with the Rio Chagres, the bed of which is followed for about 23 miles, from Obispo to the low lands on the Caribbean coast, by the line of the future canal.

FIG. 5.



Diurnal curve of barometric pressure at Alhajuela. (1) Mean of the four dry months for four years, mean pressure, 759·99 millimetres (2) mean of eight rainy months for four years, mean pressure, 759·72 millimetres.

Recent records accord with earlier data in demonstrating the remarkable uniformity of barometric pressure throughout the Isthmus. For example, the extreme range at Alhajuela during four years has been only 0·42 inch, the maximum reading, 30·99 inches, being noted in February, 1900, and the minimum, 29·67 inches, in November, 1902. The horary variations may best be studied in the form of departures from the mean reading, which enable a direct comparison to be made between the curves in the dry and rainy seasons, as shown in Fig. 5.

Although considerable mortality attended the operations of the first canal company it never reached the dimensions conceived by popular imagination. After the *débâcle* of 1888 and the revelations of the liquidation period no charge which could be brought against the de Lesseps' administration was too serious for belief. This was especially the case as regards its treatment of imported labour and the shortcomings of its health department. As a matter of fact, corrupt and inefficient as was the de Lesseps' *régime* in all that related to finance and engineering, the gravest accusations which could with justice be urged in connexion with its medical and sanitary services were that each was lavishly extravagant, that the expenditure involved was absurdly disproportionate to the results achieved, and that its returns as given to the public could seldom be relied upon. One consequence of the not unwarranted prejudice provoked by the scandalous disclosures which followed the failure of the first determined attempt to pierce the Central American isthmus may be found to day in current ideas respecting the mortality and sickness involved in the endeavour. There is little doubt that in the majority of instances people have debited to the de Lesseps company events of half a century earlier, when the Panama railroad was in course of construction and the most elementary principles of medicine and sanitation, as we know them, were flagrantly defied both as regards white and coloured labour.

The health statistics, if such were ever compiled, during the building of the Panama railroad have never been made public. Several contemporary writers, however, have left us their impressions and among these mention may be made of Dr. J. A. Liddell. This authority has recorded, in a paper in the *New York Journal of Medicine*, vol. viii., 1852, that of 382 patients treated by himself during a year's service on the Isthmus no fewer than 250 suffered from remittent fever with bilious, gastric, or enteric complications. He also pointed out that labourers from the United States could not be relied upon for three successive months; before the end of the second month one-half the force would be on the sick list or permanently enfeebled. Little imagination is required to picture the appalling mortality which must have attended the enterprise, for at that time it was not understood—or, if understood, the lesson was ignored—that natives of the temperate zones cannot with any measure of safety perform arduous manual labour under exposure to a tropical sun, and that the most that can be expected from the white man in such a climate is the performance of duties of supervision. Even in the early years of the French operations on the canal these principles were occasionally neglected, with, of course, serious consequences. There is also little doubt that much of the mortality of this period might have been prevented by a larger provision of drainage works, a more rigid enforcement of sanitary regulations, and the exclusion of employés, European as well as coloured labourers, whose mode of life and constitutions unfitted them for work in the tropics.

There still exists much diversity of opinion as to the amount of confidence which can be placed in the figures relating to health conditions which have from time to time been circulated by, or on behalf of, the French canal companies. The latter were obviously prejudiced in favour of returns calculated to cheer their shareholders and employés, and at the same time to create an impression in the outside world that affairs on the Isthmus were subject to continuous amelioration. Consequently it is not very surprising that the official statistics fail to show that high mortality from diseases incident to the climate which has been suggested by travellers and independent observers There is no doubt that during the early years of the de Lesseps' *régime* gross sanitary abuses prevailed and that the system of charging the contractors for the care of their men when in hospital was the cause of much mortality being unreported and of labourers being kept at work when they should have been under medical care Of the state of affairs when the canal was commenced we may learn much from a paper contributed to the *Boston Medical and Surgical Journal*, vol cvi, No 16, 1882, by Dr A C Heffenger This authority declared that it was impossible for him to obtain access to the records of the company and that all his investigations pointed to the conclusion that the reports issued by the latter were garbled and incorrect He states, indeed, on the authority of a physician resident in Panama, that during the first 11 months of preliminary work on the canal, when there cannot have been a very large force on the Isthmus, no fewer than 65 Europeans and 800 labourers died from disease Dr H Davidson, in his "Geographical Pathology," published in 1892, remarks that, with a force of 7000 men, the Compagnie universelle reckoned to have about 1000 men always in hospital, and from other sources we learn that, in March and April, 1882, in Panama and its vicinity alone, there died 37 out of fewer than 100 engineers, that "there was not a single French engineer who had been able to attend to the work beyond one year and a half although the contract called for two," and that during September, 1884, the company buried 654 officers and men

In face of these statements and of others of like tendency, to which it is unnecessary to refer in other than general terms, I cannot ask readers to accept as other than approximate many of the figures included in Table IV At the same time I wish it clearly to be understood that this reservation in no way reflects upon the good faith of the distinguished authority to whose labours I am indebted for these statistics Dr Lacroisade was for many years chief medical director of the well equipped hospital at Ancon erected by the de Lesseps Company, no one has fuller knowledge than he of Isthmian conditions, and his views on the subject are entitled to careful consideration It is of undoubted interest to note in connexion with this table that whereas the percentages of sickness and mortality for general ailments remained comparatively unchanged during the successive epochs, they fell in marked degree in later years for diseases incident to the climate Dr Lacroisade cannot, I think, be wrong in attributing this improvement to the better accommodation provided for the labourers, to the stricter surveillance inaugurated by the Compagnie nouvelle, to a gradual re clearing of the route, and especially to the fact that the excavations in recent years have reached a level below the poisonous emanations of decaying organic matter

TABLE IV —*Official Health Statistics of the Panama Canal*

Years	Average effective force employed	Percentage of disease			Percentage of mortality		
		Diseases of Europe	Diseases due to climate	Total	Diseases of Europe	Diseases due to climate	Total
Compagnie universelle du Canal Interoceanic de Panama (de Lesseps Company)—

Mean	2,703	20·92	8·71	37·17	2·10	0·51	2·61

Some explanations seem desirable to account for certain of the fluctuations observable in the above table Considerations of space forbid more than cursory mention of these expository circumstances, the reader being referred for a fuller hygienic history of the period to the valuable report issued in 1899 of the commission constituted under Article 75 of the statute incorporating the New Panama Canal Company and to a letter by Dr Lacroisade published in the *Medical News*, vol lxxx, p 707, New York, 1902 It will, of course, be understood that all the figures given below are quoted from the official records and, consequently, not above suspicion For example, I cannot but think that the number of recorded deaths during the years 1881–88—namely, 4987, of which 1018 were attributed to yellow fever—represents very imperfectly the actual condition of affairs and the same must be said of the statements that of the 254 engineers and other officials sent out from France from January, 1881, to September, 1883, but 40 died and that of 89 serving under the Compagnie nouvelle in an equivalent period only three fell victims to the climate

Reverting more particularly to Table IV, it may be noted that the increased percentages in 1887 are attributed to epidemics of small pox and beri beri, which were suppressed by vaccination and the discharge of Chinese and African labourers In 1898 no yellow fever or other epidemic disease visited the Isthmus, and despite the acknowledged large percentages of sickness and mortality observable in the table the general health of the canal employés was reported as satisfactory Between May and the middle of December in the following year there were about 139 cases of yellow fever in the city of Panama, the victims being chiefly foreign sailors and Colombian soldiers from the mainland A Frenchman, recently arrived and employed on the harbour works at La Boca, contracted the disease but recovered and with this exception no sickness of an epidemic form was reported among the Canal Company's employés Outside the canal region, however, in June and July, there was a sharp outbreak of influenza and in September an epidemic of measles caused numerous deaths In March, 1900, yellow fever reappeared in Panama and between that date and Sept 10th 138 cases were reported in the city chiefly among the Colombian soldiers One employé of the Canal Company was also attacked but recovered, and with this exception, according to the reports, there was no sickness of an epidemic form, the somewhat higher death rate being attributed to chronic diseases of a general type In 1901, also, no epidemic appeared among the canal force, to the Isthmus, however, in January yellow fever was again imported by a priest and sister of charity coming from Buenaventura Altogether there were four cases, of which three proved fatal There was a serious outbreak of small pox in April in the city of Panama and this

than a year, thanks,
Company in the matter

(To be continued)

H R H the Princess Louise, Duchess of Argyll, has signified her intention of being present at the Café Chantant which is to take place at the Hotel Cecil, Strand, London, on Wednesday afternoon, July 5th, in aid of the Regimental Homes and Benefits Agency.

ANCIENT EGYPTIAN BURIAL RITES.

IN a leading article in THE LANCET some years ago upon the Ethnological Significance of Ancient Egyptian Burial Rites[1] a somewhat full description was furnished of the early prehistoric interments of Egypt, from which we find that the skeleton was completely broken up and the bones were arranged in a symmetrical order in a cavity in the sand, which in those primitive times served as a sepulchre. It was considered that these kind of burials were those of a race different from that of the so-called "ancient Egyptians" and that all historical traces of the burial practices of what may be termed these proto-Egyptians had been lost, though some very obscure texts in the oldest magic funerary literature of the Egyptians were thought to refer to the matter. M. Moret, however, in a recent work upon the "Daily Divine Worship in the Egyptian Temples" in referring to several chapters, some of them accompanied by illustrative vignettes, inscribed upon tombs, edifices, or papyri, proves that a whole series of ritualistic incantations allude to, and indeed derive their origin from, these ancient funerary practices. The proof of the first fact occurs very convincingly in Chapters 20 and 21 of the "Ritual of Ammon," preserved upon a papyrus now at Berlin, and also upon the walls of some temples, a work that has only recently been translated. It speaks of the presentation, as an act of worship to the god, of perfume and oil on purpose to produce the orderly rearrangement of his bones and members, actually asserting that his skeleton will be put in order. At the same time other passages of the ritual speak of the deity as a mummy, thus indicating that in the diurnal temple worship, for this papyrus is the rubric for this official cult, not only was the god assimilated to a mummified hero, but that he also had to be adored by acts or incantations necessitated by recollections of the archaic methods of Egyptian burials previously to mummification being invented or introduced by some other people. These ancient rituals therefore afford a mingling of the practices of the alien races or of the earlier and the later ones of the same people.

The skeletons discovered by Professor Petrie and M. Amelineau and M. de Morgan upon sites of the earliest Egyptian places of sepulture had been effectually disarticulated and carefully rearranged; and the fact that the ritual for the worship of the gods, in many cases deified ancestors and chiefs, contains texts speaking of the replacing, or rather the readjustment, of the bones of the skeleton to their original serial order distinctly declares a recollection of an epoch in which the skeleton was broken [illegible] and arranged quite otherwise than in life. The idea that the reconstruction of the dismembered body was a necessity in order that the spirit might again have a tenement to occupy runs through the rubrics required to [illegible] recited at religious fêtes through almost all Egyptian history; though to what extent the many generations of [illegible] who recited, and of people who read and heard them, [illegible] prehended their origin and significance we do not know, [illegible] so far as we are aware, for thousands of years mummifying had been considered the only proper method for disposal of the cadaver. The early dynasty "Pyramid Texts" [illegible] "Maut gives thee thy head, she makes thee present of [illegible] bones, she assembles thy flesh, and brings to you your [illegible] placing it in thy breast." It was Osiris who first had [illegible] broken up according to the myths. Inscriptions state [illegible] two goddesses took care of his head and nape. However, [illegible] Osirian myths, such as "The Book of the Rites of [illegible] published by M. Paul Pierret, refer more to the [illegible] ing and uniting in their natural order of his limbs [illegible] with the flesh. But some depict first the re- [illegible] ge of his bones like so many phrases in the [illegible] of Ammon and Maut" and the "Pyramid Texts," [illegible] these: "For one to offer to the God his skull and his [illegible] e establishes his head upon his bones "before Seb," [illegible] offer to thee thy bones, thou hast taken thy head [illegible]."

[illegible] has been said to show convincingly, as suggested [illegible] vious account of the subject, that many sacred [illegible] allusions to the archaic practice of removing the [illegible] articulating the bones, and packing them together as found [illegible] logists [illegible] the [illegible] and M. [illegible] both the [illegible] to disar [illegible] when [illegible] motest [illegible] valley. [illegible] others [illegible] necessity [illegible] flesh (or [illegible] destructibl [illegible] the viscera [illegible] ing process [illegible] cantations [illegible] deity in [illegible] replacing th [illegible]

That orig [illegible] skeleton was [illegible] and the fad [illegible] only his body [illegible] evident by the [illegible] Chapter 44 of [illegible] of Maut": "H [illegible] his father Osi [illegible] of the Gazelle [illegible] bones, he reun [illegible] flesh." The rit [illegible] the offerings of [illegible] libations of pur [illegible] thy bones also a [illegible] These are intern [illegible] religious works, s [illegible] by Signor Schiap [illegible] edited by Professo [illegible] them seems to be [illegible] the deity, changed [illegible] god symbolical of [illegible] there any trace of [illegible] incineration is not a [illegible] practice are visible i [illegible]

It would seem as if [illegible] mummified their dea [illegible] probably earlier, trib [illegible] their dead, was slain, [illegible] practices of his foes, [illegible] followers after some s [illegible] Later the story of [illegible] attenuated into one of [illegible] the various provinces of portions of his body. The earliest funerary rituals contemporary with the dismemberment practices were incorporated with the later ones composed by the race who invented mummification, and as this later practice endured for thousands of years and the literature was frequently augmented during that period the passages agreeing with, or referring to, the later process are much the more numerous and, indeed, the meaning of those relating to the primitive practice was forgotten.

INDIAN MEDICAL SERVICE.

PRESENTATION OF PRIZES AT NETLEY.

THE following list shows the aggregate marks obtained by the lieutenants recently admitted into the Indian Medical Service at the Royal Army Medical College, London, and at Netley, and the prizes gained:—

	Marks.		Marks.
A. F. Hamilton	*3894	M. R. C. MacWatters	3413
A. D. White	†3641	W. H. Boalth	3399
M. F. Reany	‡3504	G. A. Soltau	3387
R. K. White	3481	W. H. Hamilton	3326
H. C. Buckley	3451	J. Cunningham	3311
N. M. Wilson	3420	H. Falk	3295
J. S. O'Neill	‖3414	C. J. Coppinger	3280

* Marshall Webb medal and prize in hospital administration; second Montefiore prize in military surgery.
† Ranald Martin gold medal in military medicine.
‡ First Montefiore prize in military surgery.
‖ Maclean prize in clinical medicine.

A presentation of prizes took place on May 31st in the lecture theatre of the Royal Victoria Hospital, Netley. President Surgeon-General A. M. Branfoot, C.I.E., I.M.S., [illegible] of the Medical Board at the India Office, presided and was supported by Surgeon General R H Quill, R A M C, principal medical officer, and the staff of the hospital The occasion derived a special interest from the circumstance that it marked the final closure of the Army Medical School at Netley

Colonel K MACLEOD, I M S (retired), read a report of the work done during the session and referred to the extinction of the school in these words "It is understood that this is the last occasion on which officers entering the Indian Medical Service will be sent to Netley for instruction In these circumstances, and as the final closing of the Army Medical School at Netley coincides with the termination of my tenure of the office of professor of military medicine, I venture to offer a few remarks arising from the situation On July 29th, 1902, His Excellency Field-Marshal Earl Roberts presided at the distribution of prizes at the end of the summer session which preceded the transfer of the school to London On that occasion, which signalised the closure of the Army Medical School as originally constituted, I read a short report setting forth the history, objects, and work of the school As that report was published at the time I need not now repeat what I then wrote The school had been in existence for 42 years and had completed 84 sessions 1687 officers of the British Medical Service, 1191 of the Indian Medical Service, and 213 of the Naval Medical Service had passed through Netley, giving a total of 3097 In addition over 300 senior officers had come to Netley for instruction Since the year 1902 127 officers entering the Indian Medical Service have been sent to this hospital, after studying the subjects of hygiene, pathology, military surgery, and hospital administration in the Royal Army Medical College, London, for the purpose of undergoing instruction in tropical diseases, lunacy, and ambulance drill and obtaining a practical knowledge of the administration and management of military hospitals and an initiation into the ways of military life and service This has raised the total of Indian medical officers trained at Netley to 1318 Since the Indian Medical Service was reopened in 1865 all officers joining have passed through the army medical school in close association with officers of the sister service The name Netley, with all that it represents in the way of instruction, initiation, and social enjoyment, must abide lovingly in the minds and memories of officers of both services, just as the name Haileybury claimed the fond remembrance of Indian civilians and the name Addiscombe of Indian gunners and sappers in the old time, and as it is to be hoped the name Millbank, despite its ancient association with a penitentiary, will dwell kindly in the recollections of officers of the medical services in the future During the six sessions that have elapsed since the transfer of the school to London and its reconstitution as the Royal Army Medical College the position of what remains of the old Army Medical School at Netley has been somewhat anomalous, but with the willing and generous cooperation of the principal medical officer and the staff of the hospital no friction or difficulty has been encountered, a circumstance of which I desire now to make thankful acknowledgment

Surgeon General BRANFOOT presented the prizes to the successful competitors and remarked that it gave him great pleasure to preside on so interesting an occasion and to be [illegible] Quill who had been at Netley [illegible] om he had not had the pleasure [illegible] sociated himself heartily with what Colonel MacLeod had said regarding the valuable assistance which the principal medical officer and the hospital staff so efficiently rendered in carrying on the work of instruction and training at Netley The Army Medical School had served a great purpose in the past for the prevention of disease and the preservation of health in the navy and the army as well as in civil life, both in this and other countries, and the final closure of the institution could not fail to excite feelings of interest and regret among those who had passed through it The removal of the school to the centre of life and progress and its reconstitution on a broader basis and with higher aims would no doubt conduce to the benefit of the services, of medical science, and of humanity What precise arrangements were to be made in the future for perpetuating and developing the work commenced and carried on for nearly half a century at Netley he was unable to announce, but he was in a position to say that the Indian Medical Service would share fully in the advantages to be gained from the college, the erection of which had been commenced at Millbank. Surgeon General Branfoot referred to the early retirement of two of the professors of the Army Medical School, Surgeon General W. F. Stevenson, C B, and Colonel McLeod The former had been asked to preside on this occasion but unfortunately had found himself unable to come He alluded to the good work done in the service and school by these officers He congratulated those who had entered the Indian Medical Service and especially the prize takers He counselled them to maintain the habit of work in spite of climatic hindrances, for once lost it was very difficult to regain it They must uphold a high standard of professional ethics in a country where the medical profession was in a stage of adolescence and development and the force of example and guidance was peculiarly needful and effective Notwithstanding the recent brilliant advances which had been made in their knowledge of the etiology of tropical diseases they would find abundance of work awaiting them in India, more especially as regards the adaptation of increased knowledge to the circumstances and peculiarities of its inhabitants The climate was no doubt trying to health, but more blame was perhaps laid on it than was justly due They must, as prudent and sensible men, hold a proper balance between work and recreation and practise moderation and a wise adaptation to their new environment He finally wished them God speed in full confidence that one and all would do their utmost to maintain the fine traditions and honour of the service to which they were now admitted "traditions which we who have retired from it very jealously cherish "

MEDICINE AND THE LAW.

Aged One Minute

OCCASIONALLY this entry is seen on a certificate of death It indicates the speedy exit of a newly born child Such a case came before Dr W Wynn Westcott last week He held an inquest upon a male child who was born living although the face was covered with "a caul " Owing to the incredible inattention of a woman assisting at the confinement the child, whose heart was visibly pulsating and whose limbs moved after birth, was allowed to "expire" without ever having had an opportunity to breathe When tardily summoned medical aid arrived the child was too asphyxiated to be revived This case enforces the fact that before a child can be positively asserted to have been live born the direct evidence of eye witnesses is often essential if doubt arises, and further, to be able to deny live birth it is not enough to prove by anatomical examination that the child s lungs have never been inflated by breathing The child in question was undoubtedly alive when expelled from the mother and the coroner was correct in directing the parents to choose forthwith a name for their deceased son and to proceed to the registrar's office and register his birth The coroner's certificate of death allowed them to have the body duly buried but of course not as inexpensively as if it had been *stillborn* The definition of "a stillborn child" is still a matter for dispute and probably should not be identical with that of "a dead born child " In fact, it would appear that the phrase "stillborn" originally signified "silent born", the "still" days of Lent convey a similar idea It is noteworthy that in France a child must live for three days before the birth is registrable

A Child ‘ En Ventre sa Mere ”

The legal position of a child *en ventre sa mere* has been much canvassed in courts of justice In the Chancery Division the question whether such a child is "living" at [illegible]

of murder in a criminal court That the Chancery judges will regard a child *en ventre sa mere* as a living child was acknowledged in a case which was heard in 1895 It appeared that property was devised to the testator's wife for her life and after her death to the testator s daughter "for her absolute use and benefit in case she has issue living at the death of my [the testator's] wife, but in case she has no issue then living" then the property was to go elsewhere When the testator s wife died his daughter was *enceinte* It was held that she had issue living at her mother's death and was therefore entitled to take the property absolutely The law upon the subject was thus stated in Blackstone's "Commentaries" "An infant *en ventre sa mère*, or in the mother's womb, is supposed in law to be born for many purposes. It is capable of having a legacy or a surrender of copyhold estate made to it. It may have a guardian assigned to it and it is enabled to have an estate limited to its use and to take afterwards by such limitation as if it were then actually born." In a case which was heard last week by Mr. Justice Swinfen Eady an attempt was made to extend this doctrine. It appears that a testator referred to "sons of his brother born in the testator's lifetime" and it was contended that this expression must be held in law to include a child *en ventre sa mère* at the date of the testator's death. The learned judge refused to accept this argument which, he said, would have the effect of adding to the will the words "or in due time after his death." It follows, therefore, that the word "born" when it occurs in this connotation must be strictly interpreted.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

THE EXCURSION TO VICHY.

(BY ONE OF OUR SPECIAL COMMISSIONERS.)

ON Sunday, May 14th, the British visitors set forth for various excursions. Some of these had been planned at the eleventh hour. The principal excursion, denominated the official excursion because it was from the first mentioned on all the official programmes, consisted of a visit to Vichy and Evian. This expedition was admirably organised. Each person who had notified his intention to attend received on the day before starting his railway pass and a small book of instructions. In this were stated the hour of the departure from Paris, the name of the hotel, and the number of the room retained for him at Vichy; then the hour of the banquet and the number of the stall for the theatrical performance after the banquet, and thus throughout all the necessary indications were given. A special first-class corridor train had been secured and by 1 o'clock the guests began to assemble on the platform of the Lyons railway station. A restaurant car was attached to the train and a cold collation was available for those who had not been able to take their second breakfast or lunch before starting. Here, also, later in the afternoon tea was served. The corridor train greatly facilitated social amenities. Visits were interchanged from compartment to compartment just as occurs between the occupants of the boxes at the opera in the intervals of the performance. As there were more than 100 travellers in the train, of whom 41 were British visitors, there was neither lack of society nor flagging of conversation. Thus was the journey of five and a half hours' duration pleasantly accomplished. At the station of Vichy the visitors were shown into the reception room reserved for state occasions but they were not detained there any length of time by speeches. Dr. Nivière, President of the Medical Society of Vichy, in three or four sentences offered to all a hearty welcome and then led the way to the omnibuses and carriages waiting outside. Here, profiting by the Sunday holiday, a vast crowd had assembled to enjoy a good stare at *les médecins anglais et leurs dames*, the latter undoubtedly exciting the greatest curiosity. Some of the crowd cheered, others even attempted to push the carriages along, and it was quite evident that the advent of the British visitors was favourably considered by the general population of Vichy. An hour was allowed for dressing and then all the visitors assembled in the gaming room of the Casino, which, in consequence of its vast dimensions, had been selected for the banquet. The brilliancy of the scene was enhanced by the uniforms of the military surgeons of the garrison who made a point of being present to welcome their British colleagues.

After an elaborate and sumptuous repast the director of the Vichy Company, M. FÈRE, rose to propose the health of His Majesty King Edward VII. and Sir WILLIAM BROADBENT responded by proposing the health of the President of the French Republic, M. Loubet. Of course, the band accompanied these loyal toasts with the national airs of the two nations. Then M. FÈRE rose again to address himself especially to the visitors. He regretted that their sojourn would be so brief but hoped to be able to show them that which was most interesting. For the present evening they could only see the pleasure side but on the morrow they would visit the vast bathing establishment which had recently been transformed. They would also go to the various springs and have a glimpse of the smiling and open country around them, as this was such an important sanitary advantage and was a precious instrument in the hands of medical science. He was glad to say that every year several thousands of English visitors and invalids came to Vichy and their presence had helped to engender *l'entente cordiale* they were celebrating that day.

Dr. NIVIERE, President of the Medical Society of Vichy, having added some further words of welcome, Dr. HUCHARD responded on behalf of the French visitors to Vichy. Then he alluded to the great benefit for the cause of science and of peace which was likely to accrue from the visit of the British medical men. In this respect he wished to propose a toast; he wanted to drink to the absent, to the modest medical practitioners of France who had sent numerous letters of greeting and fraternal salutations to their colleagues of Great Britain. They were all highly honourable men but they were too poor and too busy to be present in person. Then he would also thank the Government of the French Republic for strengthening the friendship between the two countries by conferring the Commandership of the Legion of Honour on Sir William Broadbent. This distinction given to the chief of the British visitors was an honour conferred on them all. Finally, he saluted the ladies present, alluded to Her Majesty Queen Alexandra, and spoke of the triple alliance of learning, goodness, and beauty.

Professor CORNIL of the Paris Academy of Medicine also referred to triple attributes and forces and was most eloquent when he spoke of science, humanity, and woman. But at the same time he gave a historical sketch of the development of the thermal station. He related how Louis XIV. appreciated the waters and how *les Dames de France*, sisters of Louis XVI., came in the reign of Louis XV. and gave endowments so that the springs of Vichy should be well cared for. In the time of Charles X. the Duchess du Berry greatly benefited from the waters. Nevertheless, Vichy as it was known to-day was essentially the creation of Napoleon III. It was in 1863 that the late Emperor planned the whole modern town, traced the boulevard, had the embankment of the Allier built, and the bridge thrown over the river. Five years ago the contract between the State, which owns the springs, and the company which is responsible for the entire enterprise was renewed but only on the condition that very great improvements should be effected and that a much higher rent should be paid to the State. Thus the nation at large had secured a better share in the profits that accrue.

M. LASTEYRAS, the Mayor of Vichy, was the next speaker, and he distinguished himself by the brevity of his speech and the clearness with which he made himself heard. It was a double pleasure, he said, for him to receive the British visitors, first, because the British were old friends, and, secondly, because of the new honour that had been conferred upon them in the person of Sir William Broadbent. He drank to the British nation, the friend of France since the events that had been dear to them all.

Dr. CHARLES CORMACK, a British physician practising at Vichy, addressed himself principally to his French medical colleagues but he also described the advantages to be found at Vichy for the treatment of various diseases.

Sir WILLIAM BROADBENT then rose to reply and to offer his best thanks. So many happy thoughts, he said, and good words had been expressed that it was extremely difficult to follow them and to vie with such eloquence. He gave a lengthy account of his knowledge of the leading French medical teachers and the revolution which Laennec and others had effected in the science of healing. Any honour coming from a country that had rendered such services to humanity was greatly to be appreciated. The Commandership of the Legion of Honour which had been conferred upon him was so exalted a distinction that he was confused and overwhelmed. If he failed to express all that he felt his feelings were none the less deep and sincere.

All these speeches were not over till after 10 o'clock and then the guests were invited across the great central hall of the Casino to the theatre. This is a very fine building, easy of access, spacious, and airy. There are 1400 stalls, from all of which an equally good view of the stage can be obtained. Here the best singers and actors not only of France but of other countries may be heard during the season. Thus if Coquelin or Sarah Bernhardt comes to Vichy occasionally so also may be seen, and on the same stage, the incomparable Italian actress La Duse On the present occasion there was only time for a short play, and Edmond Rostand s comedy, *Les Romanesques*, was very effectively rendered

At 9 o'clock on Monday morning carriages were ready at the hotel doors to take the visitors round The first place inspected was the manufactory where are made the Vichy pastilles Here are great cylinders where 5000 litres of water can be evaporated in an hour The salts that result if dissolved in the proportion of five grammes in a litre of pure spring water reconstitute the mineralisation of the, Vichy water Not that this is a perfect imitation, but it is a good substitute when the water itself cannot be obtained The same salt is pulverised, mixed with sugar and mint or other flavouring extract, and forms the well known Vichy pastilles Last year no less than 85,283 kilogrammes of salts were extracted from the water and thus employed These salts are placed on trays, put into air-tight compartments, and exposed to carbonic acid gas so that they may reabsorb the carbonic acid that has been lost during the process of evaporation In pulverising the sugar great care is taken to make it pass through very fine sieves so as to remove all foreign particles of dirt On the first floor of the building some 70 women are busy all day long packing the pastilles into boxes and affixing labels

The best known springs belonging to the State were visited There are in all eight but the most frequented and celebrated are those of La Grande Grille, l'Hôpital, and Celestins, the last being the most suitable for a table water The rock on which the old convent of the Célestins stood and the surrounding park provide the object of an attractive walk and are a pleasant place for the patients to congregate, to drink the waters, and to enjoy each other s society The Hôpital spring is behind the Casino and is especially frequented by dyspeptic patients The Grande Grille is considered the most perfect example of what in the ordinary acceptation of the term, Vichy waters are supposed to be The water is hot, 41° C , and it is in temperature that these springs vary most The mineral contents of the waters are very similar In various directions round and through the parks and gardens there are covered ways where the open air can be enjoyed while sheltered from the rain or the sun Here people walk up and down, glass in hand, sipping occasionally the water which has been prescribed for them

Finally and near the railway station there are vast premises where, in the course of a year, between 15,000 000 and 16,000 000 bottles are sterilised, filled with Vichy water, corked, adorned with capsules and labels, packed, and sent off to all parts of the world This in itself is a vast business and involves a very elaborate technique to insure its being done in a cleanly, expeditious, and economical manner For instance, it is no easy matter to insure the purity of a cork It may be washed on the surface but inside organic growth can survive So at Vichy these growths are first encouraged , then, when it is thought that they are fully developed they are destroyed by exposing the corks to great heat and then to mechanical pressure

What, however, proved of the most absorbing interest to the majority of the visitors was the magnificent and newly constructed first class bathing establishment This vast edifice covers 10,000 square metres out of 32,000 square metres of land The parts of this estate not built upon serve as gardens, lawns, and roadways embellished with trees and floral ornamentation The principal façade is 170 metres in length and the establishment is 165 metres wide In the centre there is the main entrance surmounted by a monumental dome Artistic decorations and paintings abound inside and from this centre broad corridors lead in all directions What is practically necessary and useful has been provided in a manner that is artistic and pleasing to the eye Here there are 136 bathrooms and six of them being larger and more artistically decorated than the rest they are called *bains de luxe* and are reserved for those who like to spend more than is necessary so as to purchase some special privilege There are 13 different places for douches and 24 for douches with massage Here copper covered doors have to be provided to prevent the destructive effect of the mineral water Numerous dressing rooms are attached to the douche and other departments Then there are hot air baths, vapour baths, Dowsing baths, large and small and hot and cold swimming baths On the first floor provision is made for more special treatment, rectal and vaginal douches, the washing out of the stomach or the bladder, nasal and aural douches, inhalations, pulverisations, electric treatment, x rays, and so on Each bath has three taps, for hot, cold, and mineral water As a rule, the baths consist half of ordinary and half of mineral water

With the bathing there is every facility for physical exercise An excellent fencing and boxing room is provided and there are also facilities for gymnastics But for those who will not, or who cannot, take exercise there is a Zander institute where the patient is forced by machinery to make the necessary movements This 'mechano therapy ' is most ingenious and each muscle of the body can be separately exercised Thus some appliances keep the wrist or the hands in movement, others the arms, the legs, the back, or expand the chest Then there is a sort of mechanical massage by vibration or rapidly delivered slight taps, the little padded striking hammers being moved up and down the part it is desired to treat Many of these machines were evidently a source of interest to a large section of the visitors and the majority experimented with them upon themselves This in many cases led to a good deal of amusement Indeed, when once the visitors reached this part of the establishment it was a matter of some difficulty to persuade them to leave and to continue the inspection of the rest of the building At last and after visiting the library, where, by the way, it may be pointed out that any appropriate English medical works would be gratefully received, the visitors gradually found their way back to the beautiful cream-coloured hall under the great dome There they admired once more the paintings of the beautiful nymphs bathing in the Vich
rows of
that mu
substantiated by a big array of statistics Thus it appears that whereas the number of bathers was set down at 16 044 in 1861 they amounted to 40,050 in 1881 and to 71,734 in 1902

By about noon, after some three hours' unceasing investigation, the visitors were able to return to their hotels, having spent an instructive and interesting morning Breakfast, or lunch as we should say in England, was then the principal consideration Dr R Durand Fardel, consulting physician at Vichy, entertained Sir William and Lady Broadbent and several other British and French guests to *déjeuner*, which was admirably served in a private room at the Hôtel du Parc There were no speeches but much cordiality prevailed What with the lengthy menu and the animated conversation there remained only just time enough to pack and to reach the station where the special train was waiting and ready to start for Evian at 3 16 P M

Excursions to Biarritz Pau, Cauterets, Argeles, Salies de Bearn, and Arcachon

(By Frederick J McCann, M D Edin , F R C S Eng)

On Sunday, May 14th a party numbering 40, composed of British physicians and surgeons accompanied by several ladies, left Paris in a special saloon carriage for Biarritz The weather being all that could be desired an excellent view of the surrounding country was obtained and *la belle patrie* in all its springtide freshness seemed to breathe forth a joyous welcome The comfort of the travellers was enhanced by the provision of an excellent *déjeuner* and dinner served during the journey

[illegible]

to the casino being lined by enthusiastic crowds The town itself was illuminated and a salvo of cannon was fired on the arrival of the visitors The guests on alighting at the casino were received by the Maire (M Faisans) who cordially bade them welcome in a felicitous speech, to which Director General A H Klogh responded Refreshments were partaken of at the casino and *l'entente cordiale* was toasted

On the following morning the assembled guests, accompanied by the Maire and the municipal councillors, drove in special carriages to the Thermes Salins de Biarritz The arrangement of the baths was explained and the excellence of the organisation was much admired A visit was then paid to the golf club, where refreshments were offered and where a photograph was taken The visitors re entered their carriages and were driven along the Plage, whence an excellent view of the wide expanse of the sea front was obtained. A visit was paid to the English club, where refreshments were again provided, and then the guests returned to the Palace Hotel (the former palace of the Empress Eugénie). A sumptuous *déjeuner*, to which a large company had been invited, awaited the visitors on their return. A military band, sent specially from the garrison at Bayonne, discoursed sweet music during the repast. The MAIRE presided over the assembled company and in a graceful speech welcomed the British visitors. Director-General KEOGH and Mr. J. A. BLOXAM responded.

After the *déjeuner* the visitors left for Pau, which was reached at about 6 P.M. A banquet was given at the Winter Palace under the presidency of the Maire of Pau who welcomed the visitors. Amongst the guests were the Préfet of the Basses-Pyrénées and H.B.M. Vice-Consul. A concert of vocal and instrumental music followed the dinner and the excellent choral singing was a feature of this entertainment.

On Tuesday morning motor-cars were placed at the disposal of the party and a visit was paid to the château of Henri IV., which contains some fine old tapestries. The guests were then driven into the country to visit the kennels and the golf course. *Déjeuner* was provided at the Hôtel Gassion and the Hôtel de France.

Leaving Pau by train at 2 P.M. the party journeyed to Cauterets, which was reached at 3.30 P.M. A beautiful view was obtained of the snow-clad peaks of the Pyrénées and the wonderful vegetation extending upwards almost to the snow line. The reception at Cauterets was picturesque and in keeping with the magnificence of the surroundings. On the platform the Corps of Guides was drawn up in line, accompanied by their band which played the British National Anthem as the train drew up. The Guides, in their pale blue uniform with white leggings, presented a striking appearance. They were medium-sized, thick-set, bronzed mountaineers who, from their physique and bearing, were evidently accustomed to feats of endurance. The Maire of Cauterets received the visitors who then drove in procession, headed by the Guides, to the hotel where tea was served. They then embarked on the electric railway and afterwards journeyed in carriages to the Pont d'Espagne.

Cauterets, from its situation and climatic advantages, deserves to be more widely known in this country. It is situated at an altitude of 935 metres and is surrounded by lofty mountains, the snow-clad summits and luxurious vegetation of which add to the grandeur of the scene. Indeed, a trip up the mountains on the electric railway discloses a scene of magnificence and grandeur which leaves a lasting impression on the traveller. At the Pont d'Espagne a fine view was obtained of the rushing torrent which takes its source in the Lac de Gaube. The approach of a mist prevented the party from extending their excursion to the Lac but all returned to the hotel delighted with the wonderful panorama.

The best efforts of Mr. Meillon had been directed to giving the guests an excellent banquet on their return. The Maire of Cauterets again welcomed the visitors and suitable replies were made. After dinner some capital photographs were shown on the lantern by Dr. MEILLON. These illustrated the experiences of mountaineers in this region and the lucid explanations given by Dr. Meillon in English added greatly to the value of the photographic exhibition. Dancing was also enjoyed and formed a fitting conclusion to one of the most enjoyable days of the tour.

On Wednesday morning an early visit was paid to the thermal establishment and an opportunity was afforded to try the sulphur waters. These waters are specially suited for catarrhal states of the nose, the throat, and the air passages, and have already obtained considerable renown. But, time pressing, a start had to be made to catch an early train to Argelès, after an affectionate *au revoir* to Dr. Meillon and his father and to the Maire of Cauterets.

Every member of the party felt the warmth of their welcome to this picturesque spot, the pure clear air of which had, even in the short time, produced its invigorating effect and where everything had been done to add to their comfort and enjoyment. A word must be said of the great kindness of Dr. Meillon who, alike as travelling companion, guide, lecturer, and last but not least, pianist, showed his remarkable versatility and was indeed a "host in himself." He will be sure to have an enthusiastic welcome when he comes to London.

After arriving at Argelès the party visited the Medical Institute where the apparatus for the treatment of orthopædic cases was exhibited and they were later entertained to *déjeuner* at the Hôtel du Parc, which is prettily situated in a wooded garden. Speeches were made by the Maire and others. The intelligence that the Préfet of the Hautes Pyrénées was prevented from attending by an accident to his child was received with regret. The Sous-Préfet, by his cordiality and *bonhomie*, endeared himself to all the members of the party and proved an excellent substitute. His health was proposed and drunk with enthusiasm.

A drive of five miles through a beautiful bit of country took the party to Lourdes. Here a hurried visit was paid to the grotto, the sacred pool, and the church. The party then left by train for Salies-de-Béarn where they were met at the station by the Maire, Dr. Matton, and other medical men. They were conducted over the salt works and the thermal establishment. Dinner was served at the different hotels and afterwards a reception was given at the thermal establishment, followed by a concert. Speeches were made by the Maire and others and a most enjoyable evening was spent. Some of the party left for Paris, while others remained for the night at Salies-de-Béarn.

The town is situated in a Pyrenean valley and is much used as a health resort by the French and the Spanish but is not sufficiently well known in the British Isles. The climate is mild and sedative, being well suited for convalescents and nervous patients. The bromo-iodine salt springs have already obtained considerable reputation in the treatment of tubercle, anæmia, and other disorders.

Mr. Rose, the proprietor of the Grand Hôtel du Château, rendered great service to the visitors during their sojourn at Salies. Dr. Matton of Salies, to whom the idea of having this tour to the South of France was mainly due, did everything in his power to promote the comfort and enjoyment of the guests.

Some of the party journeyed on the following day to Arcachon where a delightful afternoon was spent viewing this charming health resort. A cordial invitation was extended to them to remain another day and enjoy the hospitality offered by M. de Galne (Président du Syndicat d'Initiative), Dr. Festal and M. Ferras (members of the administrative council). In the evening the party returned by train to Paris, arriving next morning at the Quai d'Orsay.

Thus terminated one of the most enjoyable tours which has ever been organised. To say that the journey through France was a triumphal progress is no exaggeration, as the kindness and hospitality of the towns visited were beyond all praise. Many graceful compliments were paid to the visitors by their French hosts and many new friendships were made. The ladies of the party were specially favoured with presents of choice flowers during the journey.

Amongst the large number of those who aided in making the visit such a pronounced success special mention must be made of the Préfet of the Hautes Pyrénées, the Sous-Préfet at Argelès, the Président of the Vallée, the Director of the Funicular Railway (who had travelled specially from Paris), the Maire of Cauterets, Dr. Meillon and his father, and last, but not least, Dr. Matton. The aid given by the British authorities was also much appreciated. The party was under the charge of Dr. Leonard P. Mark of London, an accomplished French scholar, whose uniform courtesy and tact made him popular with all the members of the party. Acting as spokesman and interpreter his services were invaluable. *Vive la France! Vive l'Entente Cordiale!*

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE annual meeting of the Fellows was held on June 3rd, Mr. Arthur Chance, the President, being in the chair. The annual report was read, which showed a prosperous year. Considerable improvements were made during the year, notably a new examination hall was opened and a perfect system of electric lighting was laid on for the entire buildings from the corporation supply. The honorary Fellowship of the College was conferred on Dr. A. Traill, Provost of Trinity College. The Carmichael prize essay was awarded to Dr. M. F. Reaney, the Barker anatomical prize to Mr. C. Cooper, the Mayne scholarship to Mr. A. N. Crawford, the Carmichael scholarship and the Stoney memorial gold medal in anatomy to Mr. J. Prendiville, and the gold medal in operative surgery to Mr. J. S. Dunne. The Stanhope gold medal, awarded by the Royal Humane Society to the person considered to have performed the bravest act of the year, was conferred on Captain Thomas Campbell Mackenzie, R.A.M.C., D.S.O., a Licentiate of the College. Six years ago he was nominated by the College for a commission in the Royal Army Medical Corps and in this short time he has won seven decorations—viz., the Stanhope gold medal, the Royal Humane Society's silver medal, the Arnott gold medal, the silver medal of the French Society for Salvage of Shipwrecks, the Distinguished Service Order, and the two medals of the South African War, with four clasps. Since the last report 16 candidates passed the examination and were admitted to the Fellowship, 67 passed the conjoint examination with the Royal College of Physicians and received the diploma in Surgery and Midwifery, 13 passed the conjoint examination with the Royal College of Physicians and received the conjoint diploma in Public Health, nine passed the examinations and received the licence in Dental Surgery, and 60 passed the conjoint preliminary examination with the Royal College of Physicians and received certificates. Eight Fellows, 42 Licentiates, and eight Licentiates in Dental Surgery died during the year. There are at present living 11 honorary Fellows, 443 ordinary Fellows, 2857 Licentiates, six honorary Diplomates in Public Health, 193 ordinary Diplomates in Public Health, and 516 Licentiates in Dental Surgery.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8133 births and 4390 deaths were registered during the week ending June 3rd. The annual rate of mortality in these towns, which had been 14·4 and 14·6 per 1000 in the two preceding weeks, further rose last week to 14·7 per 1000. In London the death-rate was 14·7 per 1000 and it also averaged 14·7 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 4·3 in Hornsey, 5·5 in Leyton, 7·3 in Hanley, 8·2 in King's Norton, 9·2 in West Ham, 9·4 in Tottenham, and 9·5 in Devonport; the highest rates were 19·3 in Newcastle-on-Tyne, 19·4 in Preston, 19·5 in Sunderland, 20·5 in Rochdale, 20·9 in Stockton-on-Tees, 22·7 in Swansea, 25·3 in Tynemouth, and 26·0 in Middlesbrough. The 4390 deaths in these towns last week included 411 which were referred to the principal infectious diseases, against 401, 442, and 414 in the three preceding weeks; of these 411 deaths, 152 resulted from measles, 118 from whooping-cough, 60 from diarrhœa, 30 from scarlet fever, 28 from diphtheria, 22 from "fever" (principally enteric), and one from small-pox. In Hornsey, Leyton, Brighton, Southampton, Wolverhampton, Walsall, Preston, York, Swansea, and in nine other smaller towns no death from any of the principal infectious diseases was registered; while the highest death-rates from these diseases were recorded in West Bromwich, Smethwick, Coventry, Warrington, Salford, Sheffield, Rotherham, Sunderland, and Tynemouth. The greatest proportional mortality from measles occurred in Willesden, Walthamstow, West Bromwich, Smethwick, Coventry, Derby, Birkenhead, Warrington, Salford, Sheffield, Sunderland, and Merthyr Tydfil; and from whooping-cough in East Ham, Hastings, Ipswich, and Tynemouth. The mortality from scarlet fever, from diphtheria, from "fever," and from diarrhœa showed no marked excess in any of the large towns. One death from small-pox was registered in Bradford, but none in any other of the large towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been 17, 15, and 10 on the three preceding Saturdays, had further fallen to nine on Saturday last, June 3rd; one new case was admitted during the week, against two, three, and none in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of last week was 2267; against 2177, 2211, and 2200 at the end of the three preceding weeks; 351 new cases were admitted during the week, against 319, 319, and 312 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 251, 226, and 218 in the three preceding weeks, rose again to 235 last week, and were 54 above the number in the corresponding period of last year. The causes of 34, or 0·8 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Nottingham, Salford, Bradford, Leeds, Hull, Newcastle-on-Tyne, and in 51 other smaller towns; the highest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·5, 16·7, and 18·1 per 1000 in the three preceding weeks, declined again to 16·9 per 1000 during the week ending June 3rd, but was 2·2 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·2 in Leith and 13·7 in Aberdeen and in Perth, to 17·8 in Greenock and 18·3 in Glasgow. The 567 deaths in the towns included 33 which were referred to measles, 24 to whooping-cough, 16 to diarrhœa, three to scarlet fever, three to "fever," and one to diphtheria. In all 80 deaths resulted from these principal infectious diseases last week, against 76 in each of the two preceding weeks. These 80 deaths were equal to an annual rate of 2·4 per 1000, which was 1·0 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 32, 26, and 30 in

again last week to 33, of

eight in Edinburgh. The

h had been 30, 25, and 24 in

again 24 last week, and included 14 in Glasgow, four in Paisley, and three in Edinburgh. The fatal cases of diarrhœa, which had been 19 and seven in the two preceding weeks, rose again last week to 16, of which seven were registered in Glasgow, four in Edinburgh, two in Dundee, and two in Aberdeen. The deaths from scarlet fever, which had been two, one, and three in the three preceding weeks, were again three last week, and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 108, 83, and 107 in the three preceding weeks, declined again last week to 88, but were slightly above the number in the corresponding period of last year. The causes of 19, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·7, 19·5, and 19·0 per 1000 in the three preceding weeks, rose again to 19·4 per 1000 during the week ending June 3rd. During the past four weeks the death-rate has averaged 20·4 per 1000, the rates during the same period being 14·5 in London and 16·6 in Edinburgh. The 141 deaths of persons belonging to Dublin registered during the week under notice were three in excess of the number in the preceding week and included eight which were referred to the principal infectious diseases, against eight, six, and four in the three preceding weeks; of these, three resulted from measles, three from whooping-cough, one from scarlet fever, and one from diarrhœa, but not any from small-pox, from diphtheria, or from "fever." These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·6 in London and 2·5 in Edinburgh. The fatal cases of measles, which had been four, two, and one in the three preceding weeks, rose again to three last week. The deaths from whooping-cough, which had been one in each of the two preceding weeks, increased last week to three. The 141 deaths in Dublin last week included 25 of children under one year of age and 34 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were slightly below the respective numbers recorded in the preceding week. Five inquest cases and seven deaths from violence were registered; and 58, or more than two-fifths, of the deaths occurred in public institutions. The causes of three, or more than 2 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: H. W. Macnamara to the *Royal Arthur* on commissioning; T. J. Crowley to the *Impr* T

Austen to the *Albemarle*. Staff Surgeons: H. B. Marriott to the *King Alfred* on recommissioning; N. L. Richards to the *Antrim* on commissioning; E. T. Meagher to the *Ramillies*; R. S. Bernard to the *President* for three months' hospital course; E. A. Penfold to the *Terrible*; A. Gaskell to the *Highflyer*; and F. J. A. Dalton to Chatham Hospital. Surgeons: F. E. Auley to the *Antrim* on commissioning; A. C. Renwick to the *Indus*; B. S. Robson to the *Skipjack*; and A. I. Sheldon to the *Pembroke* for disposal.

ROYAL ARMY MEDICAL CORPS.

Captain C. G. Thomson is appointed Medical Officer in charge of Ballykinlar Camp during the training of the Militia battalions. Major C. L. Josling, Acting Principal Medical Officer to the troops, Hong-Kong, is appointed a member of the Sanitary Board of that port.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Devonshire: Surgeon-Lieutenant M. B. Hay resigns his commission (dated June 7th, 1905). 2nd Middlesex: Surgeon-Captain (Honorary Captain in the Army) A. Thorne is granted the honorary rank of Surgeon-Major (dated May 15th, 1905).

Rifle: 1st Middlesex (Victoria and St. George's): Surgeon-Lieutenant-Colonel Pearse is granted the honorary rank of Surgeon-Colonel (dated May 8th, 1905).

Consequent upon the reorganisation of the 2nd and 3rd Volunteer Battalions of the Welsh Regiment, and the 3rd Glamorgan Volunteer Rifle Corps, His Majesty has been graciously pleased to approve of the following transfer with effect as from April 1st, 1905:—To be Medical Officer: Surgeon-Major D. Hepburn, from the 3rd Volunteer Battalion the Welsh Regiment.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Harwich Bearer Company: Lieutenant W. A. Gibb to be Captain (dated June 3rd, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon-Majors to be Surgeon-Lieutenant-Colonels: H. W. Roberts (dated Feb. 28th, 1905), W. H. Packer (dated May 26th, 1905), and J. J. de Z. Marshall (dated May 27th, 1905). Captain W. R. Matthews, Manchester Companies, Royal Army Medical Corps (Volunteers), to be Surgeon-Captain (dated June 7th, 1905). Surgeon-Captain T. F. Devane, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated June 7th, 1905).

THE WAR IN THE FAR EAST.

There is no news of a medical nature to be recorded from the seat of war nor is there likely to be any for some time to come relative to the great naval victory of Admiral Togo at Tsushima, to be henceforth known as "the battle of the Japan Sea." The most remarkable circumstance connected with that battle is the wholesale destruction, amounting to the practical annihilation, of the Russian fleet which was wrought by the Japanese at such a relatively insignificant loss to themselves. It is a platitude to say that the application of scientific discoveries to modern methods of war has revolutionised the whole system and notably so in naval warfare. When we read of the number of Russian battleships sunk and of the consequently sudden and appalling sacrifice of life entailed thereby we are naturally at a loss to see where any sort of medical service aid could by any possibility come in. The only thing that could be done with any chance of success in such circumstances would be to make an attempt at rescuing as many men as possible from drowning—an obviously difficult and hazardous undertaking under the conditions of a naval battle.

It is gratifying to learn that the wounded Admiral Rojdestvensky is making satisfactory progress and gradually regaining strength. It is estimated that it will take about two months for his recovery. The Admiral is receiving, it is needless to say, every attention on the part of the Japanese medical officers and the hospital authorities. Admiral Togo has visited his late adversary and shown all the considerate sympathy which brave men always feel for one another in such circumstances.

FOREIGN UNIVERSITY INTELLIGENCE.—*Strasburg:* Dr. Hugo Fuchs has been recognised as *privat-docent* of Anatomy.—*Tübingen:* A Professorship of Hygiene is about to be established.—*Vienna:* Dr. Karl von Stejskal has been recognised as *privat-docent* of Internal Medicine.

Correspondence.

"Audi alteram partem."

"CANCER BODIES" AND THE NORMAL REPRODUCTIVE CELL CYCLE.

To the Editors of THE LANCET.

SIRS,—I have read Dr. C. Powell White's Erasmus Wilson lecture in which, as he states in his letter in THE LANCET of June 3rd, p. 1542, he has drawn attention to the resemblances between cancer bodies and the "paranuclei" of spermatocytes. There is, of course, nothing new in this. My colleagues and I had already alluded to Borrel's work in our paper recently read before the Royal Society. The whole point of the matter lies in this: that these earlier comparisons were largely founded on the erroneous interpretation of an altogether inadequate range of facts. Consequently they at once gave way before the first breath of adverse criticism. Similarly, the passage in Dr. White's lecture in which he refers to these bodies would certainly fail at the present time to receive the assent of a cytologist conversant with the details of spermatogenesis.

As was pointed out in our paper the archoplasmic vesicles neither originate from, nor do they contain, centrosomes, but they are definite bodies formed at certain fixed periods in the normal reproductive cell cycle. In their mode of origin and development they correspond stage for stage with the so-called cancer bodies. These brief remarks are necessary to render our own position with regard to the investigation clear. We are, of course, far from wishing to detract from the value of the observations or theories of other workers in this difficult field of research.

I am, Sirs, yours faithfully,

June 6th, 1905. J. B. FARMER.

THE NATURE OF DIABETES MELLITUS.

To the Editors of THE LANCET.

SIRS,—May I be allowed space to reply to the letters of Dr. Arnold Lorand and Dr. W. Langdon Brown who have done me the honour of criticising my recent Goulstonian lectures on Diabetes Mellitus? With regard to Dr. Lorand's views, I would point out that, in accordance with the well-known logical rule that a universal proposition is upset by a single contradictory instance, the occurrence of even one authentic case of combined diabetes and myxœdema is sufficient to disprove the suggestion that an excess of thyroid secretion is the invariable basis of the former disease. Dr. Lorand appears to admit that such cases have occurred, though very rarely. Both diabetes and myxœdema being rather uncommon conditions, we could not in any case expect to find the combination with any frequency. Nevertheless, it is not impossible that diabetes may be produced by several different causes and excess of thyroid secretion may be one of them.

In reply to Dr. Langdon Brown I would say that the gist of my argument was an insistence upon an internal formation of sugar as the basis of diabetes. The admission that digestive irregularities may cause excess of sugar to be poured into the blood was merely a conc [illegible] of those who hold what I have called th [illegible] of the disease and I willingly admit the [illegible] this concession if, as Dr. Langdon Brown implies, it has been definitely proved that all carbohydrate material is invariably converted into sugar in the alimentary canal and absorbed in this form. I had thought that at least one physiologist of eminence, Dr. F. W. Pavy, maintained that some of the carbohydrates were absorbed in the form of fat and that so far absolute proof was not available in either direction. With regard to the elimination of fat in lipæmia I had not meant to imply that a direct combustion took place in the pulmonary capillaries, but that the lung tissue might be the seat of [illegible] that the fat was brought there for the [illegible] issue. I can as [illegible] with the inter [illegible] pancreatic sec [illegible] relate to the [illegible] factor at fault [illegible] quite distinct from the pancreatic juice. It might even be argued that as the pancreas is supplied with nerves the fact that the digestive juice is secreted independently of their control is in itself an argument in favour of their influence upon the internal secretion, as otherwise the nerves would be almost functionless. I admit that the action of suprarenal extract in the production of glycosuria is obscure, but for reasons given in my lectures I still think that, notwithstanding the experiments on birds quoted by Dr. Langdon Brown, a direct action on the pancreas is the simplest explanation. It is possible, however, that the action is similar to that of phloridzin. With regard to the criticism that if the fat is converted into sugar it cannot appear in the blood unchanged (lipæmia), I pointed out that in normal conditions fat appears to leave the cells in which it is contained by a process of resolution and re-formation, but that in certain circumstances (? rapid excretion by the cell) droplets of fats are extruded unchanged. I therefore suggested, or intended to suggest, that the formation of sugar in diabetes was analogous to, or identical with, the former process, while the appearance of fat in the blood—a rare condition—was an instance of the latter. Both could occur simultaneously either in the case of individual fat-cells or in different cells. As to the source of sugar in starving animals treated with phloridzin, is it proved that in a starving animal every particle of fat can be removed from the body? My recollection of the classical experiments of Voit on this subject is that in an animal which had been starved to death it was found that 97 per cent. of the fat had disappeared. In a starving (living) animal there should therefore be over 3 per cent. of fat still present. Consequently I do not think that the experiment with phloridzin upon such an animal proves the origin of sugar in proteid. The possibility of such an origin I explicitly admitted in my lectures and I must adhere to the conclusion there expressed that time and further observations are needed to settle the matter.

May I take the opportunity of adding that it has been pointed out to me recently, in answer to a question of mine, by Dr. Walter G. Smith of Dublin, that it is possible by a series of chemical substitutions to obtain sugar from glycerine, and according to Thomson and Bloxam's text-book such sugar is identical with glucose. Apologising for the length of this letter, which I have condensed as far as possible, I am, Sirs, yours faithfully,

Harley street, W., June 5th, 1905. W. CECIL BOSANQUET.

THE ALTERED TREATMENT OF PNEUMONIA DURING THE LAST QUARTER OF A CENTURY.

To the Editors of THE LANCET.

SIRS,—When I was a student of medicine I studied under, amongst other celebrated teachers, Dr. R. Dwyer Lyons, who was a Doctor of Medicine, Fellow of the College of Physicians, ex-president and Fellow of the King and Queen's College of Physicians, and M.P. for the city of Dublin. He was amongst the first rank in his profession as a sound practical physician and was connected with the medical and fever divisions of the Richmond, Whitworth, and Hardwick Hospitals, where I had every opportunity of witnessing his successful treatment of pneumonia. Dr. Lyons usually prescribed quinine internally (which he regarded more or less as a specific), coupled with suitable expectorants, and later iodide of potassium, but above all and everything [illegible] and invariably ordered, [illegible] tion of the lung or lungs [illegible] so encouraging and satisfactory that I can only remember of a single instance of death (if that can be called one due to pneumonia), in an alcoholic subject, a man, aged 56 years, in whom the post-mortem examination revealed disease of the brain, liver, and kidneys, as well as grey hepatisation of the lungs. My experience, extending over a quarter of a century in a large practice in Suffolk, is this: that during the first 15 years of that time, when I prescribed as above described, recovery invariably took place and that during the remaining ten years when I practically discarded "blistering" the results were not so uniformly satisfactory. I reluctantly discontinued counter-irritation by means of large blisters for two reasons—viz., that I found that most text-books and books of references on medicine disapproved of that mode of treatment and, secondly, ? should a consultant be called in as a second opinion he would in all probability also join in disapproval, holding to the opinion that an open surface caused by a blister was contra-indicated in a disease believed by many to be but a local manifestation of a general blood poisoning, which theory I am inclined to believe is only true in the minority and not in the majority of cases.

To sum up, blood-letting in general has gone out of fashion and has been boycotted or discarded by the medical profession; now comes the turn of blistering, so that we have jumped in half the life-time of many practitioners from one extreme to the other.

I am, Sirs, yours faithfully,

June 4th, 1905. H. IVERS KIRKPATRICK.

SOME CONSIDERATIONS CONNECTED WITH THE RELATIVE IMMUNITY OF THE JAPANESE ARMIES FROM TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—Referring to the leading article with this title in THE LANCET of May 20th, p. 1365, I think we may go further than merely to "surmise that the diet of the Japanese, no less than their admirable tactics of precaution, has saved them from the scourge of typhoid fever." I think there is now sufficient evidence to show that all infections, and especially those of the alimentary tract, are much less liable to attack vegetable feeders and abstemious individuals in general, such as are the Japanese, than those of the same class, whatever their nationality, who indulge in animal food and alcohol. Japanese soldiers, by reason of their simple diet, splendid physical training, and excellent education in hygiene, are better able to resist the devitalising conditions inseparable from a lengthy campaign than are their fellows of Western nations. In addition to the hereditary advantages conferred on the Japanese through the simple and physiological lives of generations of their ancestors, due import must be accorded to the manner in which they individually avail themselves of the modern benefits discovered by preventive medicine. In this connexion it is reported that each [illegible] and takes [illegible] rhœa. H[illegible] of typhoid fever and dysentery and what is known of their prevention, and he promptly and rationally receives and acts upon this knowledge.

I am, Sirs, yours faithfully,

London, May 31st, 1905. D. SOMMERVILLE, M.D.

THE PETITION OF THE LICENTIATES OF THE SOCIETY OF APOTHECARIES TO THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Most of the signatories to this petition will have learned by this time that the General Medical Council considers that it has no power to alter the designation of the Licentiates as desired. I am sure that I am voicing the feelings of the majority when I say that we thank the Council for the sympathetic way in which it received the petition and for the careful consideration which was given to it. There is one member, however (Dr. Norman Moore), who, if he is correctly reported, hardly treated us fairly when he hinted that we desired to claim titles which had not been earned. Surely it cannot justly be said that a person who has passed the examination in medicine, surgery, and midwifery at the Society of Apothecaries desires to assume an unearned title when he wishes to be registered as Licentiate in Medicine, Surgery, and Midwifery of that society. I do not know to what he referred when he said "they constantly heard that people who had passed a certain examination were quite as good as those who had studied at the University and who had the degree of doctor." The remark does not appear to be relevant to the subject of our petition. I am, Sirs, your faithfully,

A. RIVERS-WILLSON,

Oxford, May 30th, 1905. Chairman of the Petition Committee.

CHILDREN'S COUNTRY HOLIDAYS FUND.

To the Editors of THE LANCET.

SIRS,—May we call the attention of your readers to the needs of the Children's Country Holidays Fund, which sends poor children into the country for a fortnight during their summer holidays? In most of our London schools the fund has now become an institution. Parents and teachers recognise from different points of view the beneficial effects upon the children of a fortnight's residence in the country at a time when even to older persons the heat of London is oppressive. It is hardly too much to say that the Children's Country Holidays Fund has indicated one of the methods by which there is best hope of preventing that deterioration in the physique of our town population, of which the public has lately heard so much. In 1903 the fund sent away 34,000 children and in 1904 over 39,000. The increase in numbers shows that a real demand exists for its services and that it possesses the organisation by which that demand can be met. Only the money is lacking. We hope that when the public realise the work that is being done by the Children's Country Holidays Fund sufficient help will be forthcoming to allow of its maintaining and extending its operations. The address of the fund is 18, Buckingham-street, Strand, and the honorary treasurer is the Earl of Arran.

We are, Sirs, yours faithfully,

ALFRED LYTTELTON, } Trustees of the Children's
W. F. D. SMITH, } Country Holidays Fund.

Buckingham-street, Strand, W.C., June 3rd, 1905.

A PLEA FOR THE MORE GENERAL USE OF TUBERCULIN.

To the Editors of THE LANCET.

SIRS,—In reference to your annotation in THE LANCET of June 3rd, p. 1526, I feel convinced that many medical men who have used tuberculin will agree that a plea for its more extensive use in tuberculous affections will be a step in the right direction. There is no doubt, as you suggest, that a careful consideration and a thorough re-investigation would be the means of placing tuberculin in a position that it so much deserves. In the minds of those who have constantly used tuberculin there can be but little hesitation in giving a verdict as to its efficacy in lupus vulgaris, tuberculosis cutis, lung, and other forms of tuberculous mischief. I have used this remedy since its first discovery and have not had reason to lose faith in it or be disappointed with the good results achieved by means of its aid.

I could quote various cases of tuberculous ulcers having been permanently healed by this remedy when apparently everything else had failed and such a remedy should not be allowed to become obsolete without a thorough and impartial trial. Trusting your annotation will be the means of again bringing this remedy into prominence,

I am, Sirs, yours faithfully,

C. STANSER BOWKER.

Pontnewydd, Newport, Mon., June 6th, 1905.

RED RUBBER: ITS POSSIBLE CONNEXION WITH APPENDICITIS AND OTHER INTESTINAL DISORDERS.

To the Editors of THE LANCET.

SIRS,—A few notes I have made on this subject may be of interest to your readers. Not long since, at 10 P.M., I called in a shop kept by one of my patients to make a small purchase. Behind the counter was a young girl whom I knew well as a patient and I was surprised to see her looking so ill. She presented a picture of perfect depression. I mentioned the fact to her and she confirmed my observation, saying that she had felt very relaxed and depressed for the last two days and that she was getting worse. Her pulse was scarcely to be felt, she was pale, heavy-eyed, with cold and clammy hands. At 1 A.M., three hours after I was talking to her, I was summoned to her house to see her. I went and found her suffering from a very acute appendicitis. There was no pain felt prior to 1 A.M. She was removed to hospital next day and soon operated on for the removal of the appendix. This case gave me the idea that the cause of appendicitis was probably a something which produced first of all a general depression, that either the depression or that something causing the depression was the cause of appendicitis. On asking myself the question as to what the something could be my mind became riveted on antimony after dismissing other agents for the want of collateral symptoms. Then another question presented itself as to the source of the antimony. I learned from the girl's aunt, with whom she lived, that she was accustomed to drink daily about half a dozen bottles of non-intoxicating drinks which she bought from a shop next door. I also found that she was the only one out of a family of nine who drank these drinks; she was the only one in the household ever attacked by appendicitis. This occurrence led me to retrace my steps to many of my patients who had been victims of this dire complaint and I learnt from those I revisited—nine in all—that they also had been drinkers of non-intoxicating drinks from bottles fitted with red rubber rings. That this red rubber contains antimony there is no doubt. I have tested several pieces myself. It is insoluble in all solvents of raw rubber and gutta-percha. To confirm my test I took a dozen of these red rubber bottle rings to Mr. R. C. Cowley, Ph.C., analytical chemist, Principal of the Liverpool School of Pharmacy, and in a week I received the following letter:—

> DEAR MR. POND,—I have by means of an alkali extracted sulphide of antimony from the rubber rings you left with me last week. I have very little doubt but that alkaline waters and those containing organic acids would have a solvent action on the antimony in the rubber, particularly after the rubber has been worn and its surface roughened. I think it is sufficiently demonstrated that rubber vulcanised by sulphide of antimony (red rubber) should never be used as fittings for aerated waters on account of the strong solvent action of alkalies and organic acids on sulphide of antimony.
>
> I am, yours very truly,
>
> May 7th. R. C. COWLEY.

After receiving this letter I sent an expert in the rubber trade samples of these red rubber rings, asking him if he would kindly let me know their composition. His reply is somewhat astounding:—

> May 11th.
>
> These samples probably contain the following ingredients in this proportion: 20 pounds of rubber, 12 pounds of antimony (sulphide), five pounds of red zinc oxide, one-eighth of a pound of sulphur, and a quarter of a pound of lime.

The composition, you will note, of these red rubber rings contains not much less than one-third its weight of antimony. These red rubber rings are gradually worn down in the process of use from one-eighth of an inch in thickness to the thinness of paper, with jagged edges, and by age present innumerable cracks and become brittle. The small particles of red rubber fall into the bottles and are swallowed with the drink. I have found several particles at the bottom of beer bottles. Beer bottles and non-intoxicating drink bottles are not the only places where these red rubber rings are found. They are in syphons, sparklets, certain pickle bottles, jelly and preserved fruit bottles, &c. I have just taken from the stoppers of two beer bottles the red rubber rings. One is comparatively new, with only a slightly compressed edge but already chipped; the other is much worn as described above. These two rings are the same size in depth, thickness at unworn or upper edge, and circumference. The new one weighs 28 grains, the old one only 19 grains, due to the thinning or wearing away of its lower edge. The difference represents nine grains or its equivalent—namely, nearly three grains of sulphide of antimony.

Now a few words about the probable action. The pieces of rubber are swallowed as a rule at meal time, when the stomach is full of food, and in the process of digestion I take it the antimony is slowly separated from the rubber, is slowly absorbed, and when absorbed produces its secondary action—namely, that of depression and especially as a powerful depressant of the muscle fibre of the stomach and intestines. Now, we have two factors which together are capable of producing appendicitis: (1) a relaxed muscle fibre of bowel with partial or complete paralysis of the circular muscle fibres at the orifice of the appendix; and (2) a loaded bowel (cæcum).

Now under such conditions a slight movement of the body, such as stooping or straining, or a flow of fæces through the ileo-cæcal valve into an already overloaded cæcum deprived of its muscular contractility, is sufficient to press anything in the neighbourhood of the appendix, on account of its relaxed muscular coat, into its blind canal. Again, we know that ingested antimony is excreted by the skin, kidneys, and all mucous surfaces and that this tends to inflammation of these surfaces; therefore if antimony is being excreted by the mucous membrane in or in the neighbourhood of the appendix the mucous membrane would be in such a condition as to inflame readily on the slightest excitation. I have also noticed that the majority of my patients who have suffered from appendicitis have been seized by the initial pain when in the recumbent position. I do not imagine that one ordinary bottle would produce any noticeable evil results even to the keenest observers, but to produce the results about which I am writing these small doses must be frequently repeated over a length of time and the properties of the antimony must be accumulative. Nor do I believe that every case of appendicitis is produced in this way, but my idea is that antimony is directly or indirectly the cause of a very large number of them.

Another set of cases in which, in my opinion, antimony plays a very important part is the dilated stomachs. These cases are by far more numerous than they were in former years. During the last few years I have met several with the lower border two or more inches below the umbilicus in strong athletic young men and in otherwise healthy girls. In all cases they have been drinkers out of bottles with red rubber fittings. I take it that the frequently repeated small doses of antimony depress and weaken the muscular coat of the stomach, and by filling a stomach in such a condition two or three times a day with food the weight of the food will gradually stretch its walls in their weakened state beyond the limit of active recontraction.

Again, I have formed the idea from observations made in my practice that antimony from the same source is responsible for a class of cases now known as "gastric ulcers devoid of the classical symptom of vomiting." I have had many of these cases pass through my practice during the last few years and I am sorry to say their numbers are increasing. I find these patients also are imbibers of non-intoxicating drinks from bottles fitted with red rubber rings. The muscle fibre of the stomach, I take it, is depressed by frequent small doses of antimony, the depression of the muscle fibre would account for the absence of vomiting, and if the mucous membrane was excreting any of the ingested antimony an inflamed area due to this excretion might form the commencement of an ulcer.

Another case of interest and on account of its connexion with antimony deserves to be mentioned—a case of chronic constipation. This case points rather markedly to the action of antimony relaxing and depressing the muscle fibres of the bowels. A lady sent for me one morning with the message to bring my bag as her maid was about to be confined. I went; the mistress met me at the door and told me that she had noticed her maid increasing in size for some time past and that now she was unable to get up and the pains had come on. I was shown to the girl's room. At first sight I had not the slightest doubt but that the girl was carrying a nine months fœtus. On examination I found there was no pregnancy but the swelling was entirely due to an enormous collection of fæces. She was taken to hospital. I heard from her mistress that she was there more than three weeks before she got rid of the original collection. Her mistress had some time since forbidden her to take beer and had in its place supplied her with non-intoxicants in screw-stoppered bottles.

In conclusion, I have endeavoured to show that the result of this ingestion of antimony may lead to: (*a*) a weakening of the muscular coats of the cæcum and vermiform appendix and the resulting appendicitis; (*b*) weakening of the muscular coats of the stomach and dilation of the stomach; (*c*) irritation of the mucous membrane of the stomach and intestines and thereby some cases of gastric and intestinal ulcers; and (*d*) weakening of the muscular coat of the intestines and some cases of chronic constipation.

I am well aware that the views here stated are open to ready criticism and that much investigation has yet to be made, but I put them forward as being a new and a quite possible cause of some of these alimentary disorders, the etiology of which has puzzled and is still puzzling the medical world. Moreover, it is very important that the dangers which may accrue from red rubber should at once become fully recognised.—I am, Sirs, yours faithfully,

F. A. POND, M.R.C.S. Eng., L.R.C.P. Lond.

Upper Parliament-street, Liverpool, June 5th, 1905.

THE GROWTH OF CANCER.

To the Editors of THE LANCET.

SIRS,—The proposition to be discussed is that a somatic cell may undergo functional involution or the converse of physiological evolution and in so doing may resume the characters of the primitive cell or unicellular organism and that a colony of such cells forms what is termed a tumour. The growth of cancer is not merely limitless but, as many observers have noted, the tumour has no nerves, while the cells seem to be relatively independent of their host. The limit to cell reproduction appears to be only conditioned by the nutrient medium. If nature be her own interpreter, in strictness the problem should be looked at from the inductive aspect and the growth of cancer should be compared with cells having limitless growth and an independent existence, with no nervous system. The protozoa fulfil these conditions and Weismann, impressed by the vast reproduction of the lower kinds, credited them with immortality. Clinically, the evidence is strong in favour of tumour cells having lost their normal function. A malignant tumour may flourish while all the other tissues are wasting; a fatty tumour may grow while the body-fat steadily decreases; in old people a cancer may arise while the organs are undergoing involution. Chemically, Blumenthal finds that the substance of cancer cells differs from that of somatic cells and that substances are present in cancer cells not found hitherto in the healthy body, while there is an intracellular ferment able to digest the albumin of its own cells and also the cells of the body. This is evidence that cancer cells have not the same function as somatic cells but is no proof that therefore they must be germ cells. The effect of erysipelas on malignant growths when cancer cells have been seen to undergo destruction by cocci suggests a comparison with infection in the protozoa and the struggle between the parasite and the host portrayed by Metchnikoff.[1] In this struggle the intracellular digestion of the protozoon plays a leading part. Further, the coccidium found by Pfeiffer and other observers in cancer when the parasite grows at the expense of the cell is capable of a similar explanation.

From the aspect of reproduction the analogy between tumour cells and the cell communities or colonies still found in the infusoria and rhizopods would seem to be even closer. Most of the forms of cell division found in tumours have been noted in protozoa and the cancer cell might be termed the analogue of the protozoon. Heterotype mitosis might be compared with the following.[2] "The unicellular animals or protozoa, having obviously no body, are directly comparable to the sex cells of the higher animals. The body is the addition which makes the difference. In a few protozoa, however, the results of the division of a unit remain associated togetl [illegible] protozoon is [illegible] of the higher [illegible] and may soon resolve itself into its component parts exactly as the primitive male cell, which has divided into a clump of spermatozoa, breaks up and sets these active units free. But the colony may be more stable and retain its continuity (like a segmented ovum), thus bridging the gulf between unicellular and multicellular organisms. In such cases certain cells are set apart as reproductive and eventually set adrift to form a fresh colony. This is the beginning of the [illegible] 'e cells." Wilson says:[3] [illegible] bserved in many of the [illegible] l unicellular plants. In [illegible] the process is of nearly [illegible] ɪzoa."

Amitosis is very rare in the higher plants and animals and cytologists think it is a for [illegible] it is fairly common botl [illegible] unicellular organisms. A [illegible] lost its normal function involves to a more primitive type is seen when a fat cell undergoes atrophy: the fat slowly vanishes and the cell becomes connective tissue and this in turn may organise into fibrous tissue. Involution is a phase of life, a lessened functional activity termed by Canstatt senile involution.[4] The highly specialised cells gradually lose their function, their place is taken by connective tissue, and sclerosis, especially arterio-sclerosis, initiates a vicious and involuting spiral. In man involution is not always physiological—diseases such as alcoholism, syphilis, gout, and chronic tuberculosis or aberrations of function, such as chronic constipation or overfeeding, all tend to hasten arterio-sclerosis. Involution is a frequent herald of cancer because the cell has lost its function; it is no longer a specialist, it is, in fact, though not always in form, less differentiated and hence tends to resume the exuberant growth of the blastoderm, asexual trophoblast, unorganised cell, or primitive protoplasm. Irritation and inflammation as a harbinger of cancer have been noted in many animals, while comparisons have been made from the over-functioning due to an effort at repair and from the similar method of cell division as seen in chronic superficial glossitis; but the essential difference would seem to be that in the one case the proliferating cells have retained their function, while in the other case their function has been lost.

[3] Wilson: The Cell in Development and Inheritance, 1904 edition.

[4] Boy-Teissier: Old Age, Twentieth Century Practice of Medicine, 1897 edition.

There is, however, another aspect of the problem. May we think that the presence of nerves in metazoa acts like a brake or check on cell production? or, to put it another way, Does the energy used for the nerve tissue withdraw the stimulus from the lower tissues? As the nervous system gets more specialised in the animal kingdom, so reproduction of species which, as we have seen, is comparable to cell division in unicellular organisms, gets less active and in advanced civilisation may result in sterility; conversely in poor or impaired nutrition, as seen in tuberculosis, fruitfulness has long been remarked. Clinically a neuroma composed of true nerve tissue is very rare, whereas many tumours have been recorded as a sequel to disease or injury of the nervous system. Campana has found changes in nerve trunks adjacent to certain sarcomata. Mr. G. L. Cheatle[5] emphasises the apparent relations between carcinoma and nerve and trophic areas. If we think of nerve and epithelium, which both arise in metazoa from the ectoderm or epiblast, as two diverging lines it is conceivable as the nervous system gets more highly specialised it would be more liable to get out of order and so lose control over the epithelial cell. Owing to lessened function the nerve cell has probably neither the time nor the ability to keep pace with the epithelial cell which from irritation proliferates rapidly and finally frees itself from nerve influence. The presence of nerves in cases of certain slow-growing fibro-myomata lends support to this view. To recapitulate, the hypothesis put forward might aptly be described as involution. From the limitless growth and absence of nerves a malignant tumour should be classed as a cœnobium of protozoa. Just as an old man may become childish or an organ undergo involution, so may the cell undergo functional involution and resume the character of the primitive cell. It is like a palimpsest when the rubbed out writing reappears. A somatic cell has evolved from the general to the special; a tumour cell has involved from the special to the general. Cancer is rare in youth because the organs are not undergoing involution; on the other hand, sarcoma is common because the step down to the primitive cell is easy, while the embryonic connective tissue, like its host, is not educated to orderly conduct. Benign tumours would not grow so fast because the more organised the tissue the greater the step down to the primitive cell. Tumour cells are atypical because they have lost their function and the greater the loss of function the greater the loss of form. Irregular cancer cells accord with the law of parasitism when with a lessened necessity for earning a living and with difficulties in the way of reproduction, the organs of multiplication increase in size and complexity. Cartilage which has no nerves would not form tumours until the cells had lost their function; though the absence of arteries would doubtless have some influence. The rate of growth of a tumour is proportional to the growth-rate of the tissue from which it arises, and other things being equal the more highly organised the tissue the slower the rate of growth. A sudden loss of function may cause atrophy of the growth as seen in mammary cancer when the breast atrophies after oöphorectomy; and over- [illegible] cause a temporary shrinkage as seen [illegible] administration. The absence of nuclei in some cancer cells suggests the most primitive protoplasm and they would seem to be a lower type than embryonal tissue, which has the potential to construct or to organise. Gemmation or budding occurs in primitive cells and this may explain metastases in tumours. Spores are found in primitive cells and this may account for the cell rests of cancer. The inability of transplanted cancers to grow in the tissues of another species and not always in those of the same species implies a nutritional factor in tumour formation. The record of many cases of spontaneous cure of cancer holds out the hope that a remedy will be found if the line of research includes pre-cancerous and post-cancerous conditions.

I am, Sirs, yours faithfully,

ARTHUR C. WILSON, M.B., Ch.B. Vict.

Formby, June 6th, 1905.

CHOLERA, PLAGUE, AND OTHER DISEASES IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE ON THE OTTOMAN BOARD OF HEALTH.)

THE cholera epidemic which had prevailed for nearly a twelvemonth in Persia appears to have come to an end. A telegram received in Constantinople at the end of April states that no case had been known to occur in any part of the country since Feb. 25th. A final report on the epidemic has recently been received by the Constantinople Board of Health from its representative on the Tehran Board of Health. Most of the facts contained in this report have already been made known to readers of THE LANCET in my previous letters but the report in question throws fresh light upon some points of interest. The epidemic is described as spreading by two main routes from the Shiah city of Kerbela, one route passing northwards and eastwards through Bagdad and Kermanshah to Tehran and Eastern Persia, and the other southwards to Basra and the shores of the Persian Gulf. The spread of the disease by the first [illegible] traced to certain caravans of pilgrims [illegible] burying grounds of Kerbela. One larg[illegible]cular, composed of several thousand pe[illegible] infection to Kermanshah, which was, however, already infected by other caravans as early as March, thence to Kengaver (about April 22nd), where it forced the sanitary cordon and took the disease to Feraspai (April 24th), to Devlet-a-bad (April 26th), to Kum (about May 15th), and finally to Tehran. Another group of pilgrims from Ghilan escaped the sanitary cordons, and passing by unguarded mountain roads brought the disease to Sanger, whence it passed to Keboutraheng and so to Hamadan and many villages near. Sultanabad was infected from Devlet-a-bad; the last-named town acted as a centre from which the following places obtained the infection: Mahallah (June 1st), Kashan (June 20th), Ispahan (July 9th), Shiraz (June 18th), and Yezd (Sept. 12th). From Tehran the disease spread in all directions and it is impossible to follow its course in detail. Kazvin was attacked about the end of July, Resht and Enzeli on August 1st or 2nd, Amol, Meshed-i-sar, and the Mazanderan province about July 15th. Khorassan was slowly invaded by the disease; it appeared in Shahroud on June 24th, in Sabzevar July 15th, and Meshed July 25th. In a northerly direction the march of the epidemic was also slow; Zendjan was not infected until August 28th; thence the disease was carried to Maragha by a body of artillery men; and from Maragha it spread to Tabriz, where as already related, it caused a most intense outbreak. The southern branch of the epidemic passed from Basra to Mohamera in June. Some time later it appeared in villages on the lower reaches of the Roud-Hillai. On June 28th it reached Kazerun and on June 18th was in Shiraz. Early in July it was present in the suburbs of Bushire. Following the course of the river Karun cholera appeared in Dizful and Shuster on July 13th. Finally some of the islands of the Persian Gulf were invaded by the disease and ultimately the whole of the Persian coast is said to have been infected as far as the frontiers of Beluchistan. Kerman obtained the infection by means of pilgrims coming from Meshed about Oct. 23rd.

It will be observed that in this epidemic, as on so many previous occasions, pilgrims have been the principal means of diffusing the disease. The measures taken to check its spread seem to have been of little use. On the appearance of cholera in Kermanshah at the end of March nine days' quarantine was established at Kasré-Shirin on the frontier and an observation post on either side of Kermanshah itself. There were no trained staff and no means of disinfection at any of these points, and, as shown above, the sanitary cordons were easily broken through. When the disease had reached Kum the Persian Government ordered quarantine to be established at points between Kum and Tehran, between Hamadan and Tehran, and to the north of Keboutraheng. Many other important roads were left entirely unguarded or were only guarded when the disease had already spread by them. When the cholera broke out in Tehran some attempt was made to protect the road to Meshed by establishing quarantine at Shahroud, but it was already too late, and the whole of the Khorassan province was sooner or later invaded. It was from this province that the infection passed over the Russian frontier by the much-frequented road between Meshed and Askhabad, and this in spite of the measures imposed at Sarakhs on the frontier. To protect Ghilan (in the direction of Southern Russia and Europe) the Customs Administration—by which most of the protective measures were executed—established two quarantine posts, one at Mendjil and the other at Enzeli. Both are said to have been undermanned and insufficiently equipped. Similar measures were adopted in Southern Persia. The road from Bushire to Shiraz was cordoned and other precautions were taken, but here, as elsewhere, they came mostly too late and were imperfect both in conception and execution. In the towns themselves it is the same story. There were no trained men already existing and no sanitary organisation of any kind and the attempt to improvise them when cholera had already broken out was found to be impossible. At some places, as at Kermanshah, where funds were adequate and where foreign assistance from the consular medical officers was available, there was opposition on the part of the people who accused the foreigners of spreading the disease by poisoning the waters "with a white powder" and even popular risings took place which made all measures impossible.

One means by which the infection was spread was the objectionable custom which appears to obtain in Persia of washing the bodies of the dead in the public baths!

One result of the epidemic in Tehran was the revival of the board of health in that city. It has since held regular meetings, the minutes of which are now printed. On the initiative of the Customs Administration a public subscription was opened and ambulances were established. The "Nasseri" ambulance and that of the Sisters of Charity of Vincent de Paul did particularly good work. A system of burial of the dead and of removing the sick was organised and numbers of bodies were removed from the streets and public places where they had been abandoned. An immense plot of land was bought to serve as a cemetery and efforts (not altogether successful) were made to insure burial of the bodies at a proper depth from the surface.

The epidemic appears to have added little or nothing to our knowledge of the pathology or treatment of cholera. Owing to popular prejudice necropsies were impossible. Most of the cases were of a severe form; relapses occurred in a few instances and were nearly always followed by death. Nothing is said as to the case mortality of the epidemic and no doubt the means of ascertaining it were unobtainable. The total mortality in Tehran was rather less than in the great epidemic of 1892. In that year the population of the city was put at 200,000, of whom about 20,000 died from the disease; in the present epidemic the population was reckoned at about 260,000, of whom some 17,000 are thought to have died. These figures are in any case only approximate; some estimated the cholera mortality at the enormous figure of 75,000, others at only 5000. But these were mere guesses; the mortality of 17,000 is based on a control of the numbers of the dead buried at the cemeteries and of the bodies washed in the public mortuaries, and also on the fact that a mason engaged by the governor of the city to cover in the graves with clay and lime sent in a bill for covering rather more than 16,000 graves. To this must be added some hundreds already covered in by the relatives, others carried to distant burying grounds, about 100 Jews, about 50 Armenians, and about 30 Fire-Worshipers. The total of 17,000 may consequently be accepted as fairly correct. The cholera mortality in the whole of Persia is reckoned at between 250,000 and 300,000, distributed as follows:—

Kermanshah...	13,000	Khorassan	13,000
Hamadan	15,000	Ispahan...	16,000
Arak...	10,000	Shiraz	30,000
Malayer-Tousserkan ...	7,000	Arabistan	22,000
Kum	10,000	Azerbaijan	30,000
Tehran	26,000	Kerman	16,000
Kasvin	8,000	Other provinces	30,000
Ghilan	14,000		
Mazanderan	12,000	Total	272,000

It will be observed that the figures for Tehran given in this table (which is quoted from the report as it stands) differ from those just given (from the same report) above. There are some other discrepancies, to which it is unnecessary to refer, in an otherwise excellent report.

A few words are added as to the lack of all sanitary arrangements in Persia. The conditions described are but too familiar elsewhere. The drinking water is brought in open channels in which people also wash their linen, bathe, and even water their cattle. A dead beast may occasionally be thrown into them. Excreta are received in deep wells, which slowly fill, and are then covered in. The soil is polluted with fæcal matter for a wide distance around. It is unnecessary to dwell on the other conditions described.

The cholera epidemic in Russia came to an end in February last. The rumours of its presence in some parts of the country in April, which appeared in the English and other papers, have been contradicted by the Russian Government in an official statement issued last month. In this statement it is declared that no case of cholera had occurred in any part of Russia since Feb. 11th (24th New Style). A suspected case occurred in the village of Bataisk, in the Don territory, on March 12th (25th), but bacteriologically it proved not to be a case of cholera. The Russian Government also states that at the end of last year it declared the following regions "threatened" with cholera: the shores of the Caspian, the [illegible] Saratof, Simbirsk, Kazan, and [illegible] ces of Transcaspia, Samarkand, [illegible] Russian settlements in the suzerainties of Bokhara and Khiva, the Uralsk province, the Don territory, and the governments of Perm, Ufa, Stavropol, Orenburg, Viatka, Tiflis, Elisavetpol, and Baku. On March 13th (26th) the governments of Yaroslavl, Kostroma, Vladimir, and Tver, all on the upper Volga, were added to the list, and those of Moscow, Tambof, and Riazan, although not declared to be "threatened," were ordered to prepare for a possible epidemic by opening "observation points" along the river.

The outbreak of plague in Aden has rapidly subsided, as shown by the following figures:—

Week ending	March	25th	41 cases	32 deaths.
"	April	1st	32 "	30 "
"	"	8th	13 "	12 "
"	"	15th	5 "	3 "
"	"	22nd	4 "	4 "
"	"	29th	14 "	8 "
"	May	6th	6 "	4 "

Two cases of epidemic cerebro-spinal meningitis have recently occurred in this city. Neither of the patients had been anywhere outside Constantinople for a considerable period. In both the diplococcus of Weichselbaum has been found in the cerebro-spinal fluid. One case has proved fatal, the other is recovering.

Both plague and typhus fever have appeared in the Assyr province of Arabia. A telegram dated March 20th reported that the outbreak of typhus fever had already led to over 80 deaths in the Beni-Sheir district of Assyr. It was added that there was no doubt as to the diagnosis and that the disease was not the plague—which had long been endemic in this region. On March 29th a second telegram reported the occurrence in the same region of three cases of endemic plague, of which one had proved fatal.

The outbreak of typhus fever in the Vladimir government of Russia, mentioned in my last letter, spread to Moscow. On March 12th (25th) there were already 30 cases of the disease in the Moscow hospitals.

Constantinople, May 18th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Dr. J. Dreschfeld's Retirement.

ON May 29th the board of management of the Manchester Royal Infirmary received a letter from Dr. Dreschfeld in which he stated that having reached the prescribed age at which he had to retire from the honorary staff of the infirmary his services as physician would cease on Sept. 30th. The board, while accepting the resignation, recorded its high appreciation of Dr. Dreschfeld's distinguished ability and the value of the services which he had so long rendered to the institution and its deep regret that the term of his services approached its close. Dr. A. T. Wilkinson, the senior assistant physician, will now become full physician. It often seems a misfortune that a brilliant and useful career in the service of a great hospital has to close when the judgment is at its ripest and the mental powers are vigorous and acute.

Infirmary Appointments.

At the same meeting the following appointments were also approved:—House physicians: Dr. E. M. Wilkins, Dr. W. H. Hey, Mr. P. R. Wrigley, Mr. C. Roberts, Dr. G. D. Dawson, and Dr. J. Smalley. House surgeons: Dr. H. Mackenzie and Mr. T. M. Hughes. Medical officer for home patients: Dr. George Ashton. The board also approved of the recommendation of the clinical laboratory committee to appoint an electrician to deal with radiography at a salary of £35 a year and that the medical director of the laboratory should have a salary of £200 a year. The chairman, Mr. W. Cobbett, stated that the change was necessary, as the clinical laboratory was said to be in an unsatisfactory condition. Medical assistance was required and also the help of a good electrician.

The Infirmary and the Ear Hospital.

At the same meeting also the chairman reminded the board that he and Mr. Charles Hopkinson had been instructed to see Dr. W. Milligan with respect to the new Ear Hospital, the erection of which has for some time been under consideration. The question was whether there should be special facilities in the new infirmary for dealing with aural cases. After communicating with Dr. Milligan they had come prepared to submit the following motion, which Mr. Hopkinson accordingly moved:—

> That, provided a new hospital for aural cases be built on the site approved by this board in close proximity to the new infirmary and opened on or before Dec. 31st, 1908, this board will not allocate any special wards or beds in the new infirmary to aural cases so long as adequate facilities for aural cases and for instruction thereon be maintained in the new Ear Hospital.

This was carried unanimously.

Infirmary and University.

As the result of an interview between a subcommittee of the infirmary board and representatives of the university, held on May 16th, it was recommended that a professor of pathology at the university be appointed on the honorary staff of the infirmary and that towards the expenses incurred by the university in maintaining the pathological department the infirmary should pay a contribution of £125, the arrangement to be terminable either by the university or the infirmary by giving six months' notice. These various changes tried to bring about more intimate relations between the infirmary and the university, to the advantage, no doubt, of both. In days gone by a state of more or less friction was not an unusual condition between the infirmary and the Owens College, perhaps arising from undue sensitiveness on the part of the older institution of what seemed to be the somewhat youthful, and perhaps the slightly imperious, self-assertion of a junior. In these latter days there is no doubt a greater display of sweet reasonableness on both sides.

Progress of the New Infirmary.

The board was informed by the clerk of the works that 260 workmen were now engaged on the foundations at the Stanley Grove site. There have been no serious difficulties experienced with the ground so far, nor have any interesting geological finds been made, as, e.g., that of the huge boulder now occupying a prominent position in the quadrangle of the College. The only discovery hitherto has been the skeleton of a horse in a spot which evidently marked the position of an old pond.

Manchester and Salford Sanitary Association: Lamp Explosions.

It may perhaps be remembered that for several years past Mr. William Thomson, F.C.S., has conducted an inve[illegible]tion into the causes of lamp explosions in [illegible] Salford. The police have ob[illegible] used and, when [illegible] such particul[illegible] chief constabl[illegible] last meeting o[illegible] J. D[illegible] presiding, Mr. [illegible] years, in which [illegible] of the police, [illegible] last eight mo[illegible] and eight mon[illegible] may be conside[illegible] of the lamp a[illegible] sometimes been [illegible] the exclusion of [illegible] causing the explos[illegible] in Manchester in [illegible] type of burner w[illegible] of the wick-tube a[illegible] reservoir of the lam[illegible] The manufacturer [illegible] Mr. Thomson's suggestion, ceased to [illegible] them several years ago and it is possible that the disuse of this dangerous burner has lessened the number of explosions." As regards the oils used, recent investigations confirm former ones as to the fact "that Russian oil was more liable to cause explosions than American 'low-flash' oil. No record of Scottish oil or 'high-flash' American oil having flash points of 100° F. or over had as yet been found among the oils which were alleged to have caused explosions."

Treatment of Pauper Children.

At a conference of the Women Guardians and Local Government Association for the Northern Counties, held in the Manchester town hall on June 1st, Miss Dendy presiding in the unavoidable absence of th[illegible] Countess of Carlisle, some [illegible] cussed. One was the Boarding[illegible] C[illegible] paper was read on this subje[illegible] inspector of the Local Govern[illegible] private capacity she admitted th[illegible]out system had grievously failed, th[illegible] when well carried out it was one difficult to improve on. She gave some hints on the best methods of visiting and inspecting the homes and seeing to the general treatment of the children.

June 6th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Physical Development of Jewish and non-Jewish Children.

THE work, which has now for some two years been carried on by Mr. William Hall, of feeding poor children at St. Peter's-square council school deserves attention, whether it is viewed from the philanthropic or from the experimental standpoint. In making an investigation some years ago into the physical conditions of children living in the slums of Leeds Mr. Hall became increasin[illegible] inequality in physical [illegible] children, comparison [illegible] *of the latter, even* w[illegible] comparison should be [illegible] age, degree of povert[illegible] systematic examination [illegible] and was conducted w[illegible] greatest care, with the result that Mr. Hall stated that the poor Jew was three pounds heavier and two inches taller than his non-Jewish brother at the age of eight years; these figures were six and a quarter pounds and two and a half inches at the age of ten, and at the age of 12 he was seven pounds heavier and one and a quarter inches taller. Bone formation was much more satisfactory in the case of the Jew, the teeth were very much better, and there was a striking absence of rickets; the nasal chamber was larger the palate was, as a rule, large and flat, and the children were remarkably free from adenoids and were nose breathers. In all these particulars the non-Jewish child of the same age was decidedly a sufferer by the comparison. This great variation Mr. Hall attributes chiefly to the difference in feeding.

in the two cases. He maintains that the Jewess during her pregnancy is fed with greater care and does not have to take so large a share in working for the maintenance of the home. It is, indeed, a matter of conscience and religion to the Jew that his wife should be tenderly cared for during this period. The Jewess is consequently able to supply natural nourishment to her offspring in a larger percentage of instances than the non-Jewish. After the time for breast feeding has passed Mr. Hall finds that the feeding carried on by the Jews is more sensible, for the food is better and more abundant and is better cooked. The non-Jewish child of the slums he finds living in imminent risk of scorbutus, if not actually scorbutic, with spongy gums, and existing, it may be, on white bread, tea, badly cooked fish, or possibly on tinned meat and pickles. The Jewish women always secure good fish, clubbing together, it may be, to get it cheap; they use vegetables freely with this in preparing an admirable, attractive, nourishing, and antiscorbutic diet. Eggs, says Mr. Hall, they *will* secure for their children even if it should be necessary to keep on their humble premises a hen which, as he amusingly says, is *expected* to produce its daily egg. As evidence of the keen desire that their children should be well fed Mr. Hall notes that groups of Jewish mothers may be seen at the gates of the schools with food for their children to take during the intervals for play. Without in any way suggesting that hereditary predisposition, overcrowding, damp and cold, and impure atmospheric conditions may not be very important factors in relation to physical development, Mr. Hall was encouraged by the above noted considerations to try the effect of an improved dietary in the case of some of the half-starved and ill-developed scholars of one of the schools in the poorest parts of Leeds, selecting for this purpose the St. Peter's-square school. With the aid of some philanthropic friends he has made arrangements for 100 of the poorest of the children attending this school to get one good meal a day. Some initial expense was involved in the purchase of cooking utensils, plates, and basins. The coal cellar was utilised as a kitchen and provided with two large gas-stoves, a boiler for milk, and a chopper for bread. The food varies; on two days there is "pie meat," haricot beans, and potatoes; on another day there may be fish and rice pudding; on Fridays there are fried tripe and onions. The quality of everything is excellent and the supply abundant. The cooking is done by two women cooks who are assisted by four girls and two boys, who wash up and act as monitors, and it is pleasant to note that every encouragement is given by the head-master. The dinners cost about 2*d*. each and towards this about half of the children pay 3*d*. a week each. The effects have been very striking, for writing on Jan. 13th Mr. Hall was able to report as follows: "I weighed 55 children aged seven to eight years—28 boys and 27 girls—on Dec. 29th. I weighed them again, some to-day and some yesterday. They had gained altogether 63 pounds, or at the rate of about two stones each per annum." In accounting for this great and immediate increase Mr. Hall points out that the tissues of these half-starved children are, like those of convalescents from acute illnesses, ready to pick up nourishment with avidity. Together with the increase in weight the children have improved in general appearance and have lost their semi-scorbutic aspect, while, as might be expected, the kindness shown to them has resulted in an improvement in their manners and in their self-respect.

Leeds Public Dispensary.

The board of management of the Leeds Public Dispensary has resolved to carry out an increase in that special part of the work of the institution which is concerned in the visiting of the patients at their own homes. Last year the number of visits made by the resident staff, who are mainly responsible for this part of the work, was 15,950. The area dealt with is divided into three districts and one resident officer visits in each district. For many years the large manufacturing districts of Hunslet and Holbeck have, with the exception of a small part of the former, been outside the area which was dealt with. It is now intended to add a large district south of the river Aire which will include the [illegible] is peculiar among the Leeds medical charities to the dispensary. There is, of course, in connexion with the dispensary a large out-patient department to which patients come from all over Leeds and from beyond its boundaries. Last year there were 71,813 attendances in the out-patient rooms and many of these patients come from south of the river. Those who are unable to attend will now be included within the visiting area and a great boon will be conferred on the district which has been added.

June 5th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Midwives Act in Denbighshire.

THE Midwives Act is being administered in the county of Denbigh by the public health committee of the county council and when the question of appointing an administrative officer was recently being discussed by the committee, Mr. Richard Evans, a medical practitioner who is a member of the committee, was asked to draw up a list of the duties which would fall upon this official. The committee was compelled to call in the assistance of Mr. Evans owing to the county council not yet having thought fit to appoint a county medical officer of health. The list of duties submitted to the committee at its last meeting includes a quarterly visit to each midwife, inspection of her case-books and bag of appliances, reporting upon cases of malpraxis or breaches of the rules of the central board, keeping a register, reporting the death of a midwife, recording stillbirths, reporting upon cases of puerperal fever, and when desired by the committee giving elementary instruction to midwives. The county council has endorsed the recommendation of the committee to ask the medical officers of health in the county to administer the Act and to pay them for the inspection and supervision required a fee of 10*s*. 6*d*. per annum for each midwife living in the district concerned. The duties are to be those drawn up by Mr. Evans. The medical officers of health have not yet decided whether they will accept this fee which does not err on the side of generosity. Compared with the fees paid for similar duties in other counties it is distinctly mean. In Cheshire a fee of one and a half guineas and in Surrey a fee of one guinea is paid for similar duties to the district medical officers of health.

Typhoid Fever at Bridgend.

In the town of Bridgend, which has a population of about 7000 persons, there have in recent years been several serious epidemics of typhoid fever. In 1899 there were 78 cases with 11 deaths and in the five subsequent years the cases have averaged 22 and the deaths three. During the first quarter of the present year there were 12 cases and two deaths and between the third week in May, when the present outbreak began, and June 1st, 29 cases were notified. Mr. Wyndham Randall, the medical officer of health, does not appear to think that there are any of the characteristic features which attend either a milk-borne or a water-borne epidemic and inclines to the opinion that the recent increase in the number of cases of the disease is due to the excessive dryness of the atmosphere, with the consequent blowing about of infected particles in dust. He has recommended the thorough watering not only of the main streets but of the back streets and bye-passages. In his report for 1904 he advised the council to provide covered iron receptacles for the removal of infected excreta, together with an incinerator for their destruction. It is possible that if his recommendation had been adopted the present epidemic would not have occurred and it is difficult to understand the refusal of the council even now to take this very proper and practical safeguard against the spread of the disease.

Schools and Infection.

A short circular bearing the signature of Dr. J. Middleton Martin, the medical officer to the Gloucestershire education [illegible] suspect that a child is suffering [illegible] send him home at once with a written note to the parent requesting that the child should be seen by a medical practitioner and a report of the opinion so obtained sent to the teacher. For this opinion it appears that the education committee is prepared to pay a fee of 1s. In connexion with school closure Dr. Martin points out that such a step taken in panic may do more harm than good because a valuable source of information as to suspected mild unrecognised cases is thus thrown away. Accompanying the circular is a leaflet giving some details with regard to the principal symptoms of infectious diseases and of contagious conditions which are liable to affect children. Included in the latter are scabies, ringworm, ophthalmia, impetigo contagiosa, and pediculosis. At a meeting of the Gloucestershire education committee held on May 27th it was resolved to request the Board of Education to amend Article 46 of the Elementary School Code of 1904 so as to provide that when an infant class and the lower standard were excluded from school attendance on account of infectious disease the "average attendance" of the children so excluded might be calculated separately from that of the older children. It was explained that that could be done by only considering the number of times the school had been open on their account, and not, as at present, the total number of times open, whether for infants or older children.

Health Report of Gloucester.

In his annual report for 1904 the former medical officer of health of the city of Gloucester (Dr. John Campbell) estimated the population of the city as 50,510 and recorded a death-rate of 14·8 per 1000 and an infantile mortality rate of 134 per 1000 births. The death-rate for pulmonary tuberculosis in 1904 was 0·9 per 1000. Dr. Campbell advocates the voluntary notification of cases of this disease and although he suggests the erection of wooden huts on the isolation hospital estate for the treatment of suitable cases he expresses the very distinct opinion that the prevention and cure of consumption are to be found in the creation of healthy homes and healthy surroundings for the people.

The Medical Officer of Health of the Chipping Sodbury Rural District.

At the meeting of the Chipping Sodbury rural district council held on May 31st a letter was read from the Local Government Board stating that it was not at present prepared to sanction the appointment of the gentleman nominated by the council as its medical officer of health in place of Dr. F. T. Bond. It was reported that the Gloucester rural district council, on the suggestion of the Local Government Board, had called a conference for June 19th of the district councils which form a combination for the appointment of a medical officer of health and had requested the Chipping Sodbury council to appoint a delegate. After a considerable discussion the latter council decided not to send a representative to the meeting.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Victoria Hospital for Consumption, Craigleith, Edinburgh.

The annual meeting of the friends and supporters of this institution was held on May 31st, when it was stated that from the date of opening of the hospital 988 patients had been under treatment in the hospital. In addition to these 133 "visitant" patients had been allowed to spend the whole day at the hospital, enjoying the *régime* and treatment and going home at night. The committee had arranged for a few contributing patients and the contribution had been fixed at a guinea per week and had also proposed to individual benefactors, heads of firms, and to smaller towns and communities a method of endowment by which a bed could be maintained within the hospital for a sum of £80 per annum, the contributor having the right of nomination to that bed throughout the year. It was also desired to establish an after-care colony and a first step had been taken in this direction. Since the date of opening 14,329 individual patients had received advice and treatment in the dispensary and out-patient department and a large number had been supervised at their own homes. The expenditure for the year had been £5774 and the income £4021. The three pavilions provided form but a small portion of the plan of the architects and
with a view to extensions on the lines of the plan a gr
international fair will be held in the Waverley Mark
Edinburgh, in November next, of which Her Majesty t
Queen has consented to become patron and when it is hop
that a sum of £12,000 may be obtained. Especial gratifi
tion was shown at the extension of the King's patron
and for the grant of the title "Royal" to the hospital.

Reconstruction of the Gla[illegible] R[illegible] Infirmary.

A scheme for [illegible] [illegible]rmary has b
more or less [illegible] [illegible] for some yea
The present [illegible] hopelessly inadequate a
antiquated and although it is with regret that one co
templates the demolition of the building in which Lis
inaugurated his work in antiseptic surgery, yet all are agr
that the time has come when it is necessary to replace it
a building which will meet the requirements of prese
day surgery and medicine. Some time ago the manag
of the infirmary invited plans for the new building from
architects and appointed Sir Rowand Anderson asse
The designs were submitted in due course and a sh
leet of four was made up by the assessor, from which
final selection was made by him and recommended
adoption. The committee not only rejected it but went o
side the entire short leet of four and chose a design wh
has not met with unanimous support from hospital expe
The Institute of Architects protested against the conduct
the competition and severely criticised the plan chosen. T
main objections urged were (1) the distribution of the bui
ings on the site in such manner as to shut out the sun a
air to almost the greatest extent possible so that ma
of the wards would be practically sunless during
great part of the year; (2) the height of the bui
ings, where, in the face of all the modern the
and practice of hospital design in limiting ward blo
to two, or at most three, storeys, those in the new bui
ings would be six storeys in height, the result either
inefficient planning or of a site inadequate for the accom
dation required; and (3) the central halls and staircases fr
top to bottom of the ward blocks permitting free interco
munication of the air between the wards. The pres
building stands in Cathedral-square, in close proximity
the Cathedral, and it is proposed to erect the new buildi
on the same site. In order to preserve the amenity of t
Cathedral, which would be completely blanketed by the h
block of buildings proposed in the new plans, a committ
has been formed, and its report, as it appeared in t
Glasgow Herald of June 3rd, runs as follows:

> The infirmary board have recently intimated that they propose
> proceed shortly with the re-erection of the buildings according to
> plans prepared and including ultimately the "Jubilee Block"
> Cathedral-square. For some years past and pending this decis

> be placed; and (2) an exact view in perspective from a point towa
> the north-west of Cathedral-square of the buildings as they wo
> appear in relation to each other at that point. The drawings speak
> themselves and show how the Cathedral is overpowered and injured
> the huge pile proposed, six storeys and basement in height and w
> turret roofs and central spire overtopping the whole. The Cathedra
> Glasgow's greatest adornment in architecture and is in many respe
> unique among buildings of its kind. That the citizens and all outs
> their number interested in this noble work of art should unite in sav
> it from the irretrievable injury proposed is the hope of the commit
> in publishing the drawings and issuing this appeal.

Another grievance has been raised in connexion with t
reconstruction scheme and that is the proposal to use ter
cotta blocks instead of stone so far as the outer walls a
concerned. The Master Masons' Association of Glasgow
a largely attended meeting protested against this propo
and sent a copy of the resolution to the managers of t
infirmary. There is no doubt that the managers have a ve
difficult task before them, but it is felt that matters mig
have gone more smoothly had they taken the public m
into their confidence.

June 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

AT a meeting of the Fellows held on June 5th the following were elected:—President: Mr. Arthur Chance. Vice-President: Mr. Henry R. Swanzy. Honorary secretary: Sir Charles A. Cameron. Council: Mr. Edward H. Bennett, Mr. William Stoker, Sir Charles Cameron, Mr. John B. Story, Sir William Thomson, Sir Charles B. Ball, Sir Thomas Myles, Mr. John Lentaigne, Mr. Richard D. Purefoy, Sir Lambert H. Ormsby, Mr. Henry G. Sherlock, Mr. R. Bolton McCausland, Mr. John S. McArdle, Mr. Robert H. Woods, Mr. Thomas Donnelly, Mr. William Taylor, Mr. Edward H. Taylor, Mr. G. Jameson Johnston, and Mr. R. Charles B. Maunsell.

The Irish Medical Association.

Notice has been received by the members of the Irish Medical Association of various motions which will be considered at the meeting to be held at Killarney on June 7th. The council recommends that Poor-law unions whose scales of salaries to their medical officers were accepted by the latter and approved by the Association shall be exempted from the rule passed at Enniskillen in June, 1903, fixing the minimum salary for dispensary officers at £200. That rigid regulation has proved a failure and it is time that it should be withdrawn. Dr. Donnelly is to make arrangements as to the next issue of the Irish Medical Directory. If this is done in a satisfactory way it will cause much expense which the Association cannot apparently well afford. The accounts show a credit balance of £90 7*s.* 5*d.*, but against this and the income for 1905 law costs estimated at £695 must be charged. As regards the famous report of Surgeon-General G. J. H. Evatt—the "fons malorum"—Mr. Arthur Chance, the President, made a statement at the annual meeting of the Fellows of the Royal College of Surgeons in Ireland held on June 3rd. He said that, referring to Surgeon-General Evatt's report, though portions of it had been published in the press the College was still unable to reply to the criticisms which had been made upon it, inasmuch as the report was still a confidential document. He appealed to the Irish Medical Association and other medical men throughout the country at once to make an effort to forget the differences which the publication of the report had caused and to work together in the cause of the profession.

The Holywood Foreshore Nuisance.

A provisional order has been made by the Local Government Board appointing a joint board consisting of three representatives from Castlereagh rural council, three from Holywood urban council, six from Belfast council, and one nominated by the Local Government Board, who will have a casting vote and be practically chairman. The costs ordered to be contributed are, by Belfast corporation 85 per cent., and by the two other councils each 7½ per cent. Belfast corporation objects on two grounds—namely, (1) that it has not sufficient representation on the board, and (2) that it has to pay too much of the expenses. On fair consideration there is nothing in either of these pleas, for suppose the members of the two other councils united to squander public money for every £1000 raised Castlereagh council would have to pay ¾*d.* in the £, Holywood 1½*d.*, and Belfast only one-sixth of a penny. The real object is to compel Belfast to make good the injury that it is inflicting, and has been inflicting for years, by discharging its unpurified sewage into Belfast Lough, the shores of which are in the districts of the Castlereagh and Holywood councils. Nearly seven years ago an influential deputation of residents in the affected areas waited on the city corporation complaining of the horrible nuisance and in 1899 by their opposition to a Bill being pushed forward by the Belfast corporation they compelled that body as a compromise to insert a clause binding themselves to purify the city sewage within three years. For two of these years the corporation did nothing and only in the third year did it carry out some preliminary works, while all the time owing to the erection of new houses the volume of additional sewage discharged into Belfast Lough was being increased. Until the new purification works for the bacterial treatment of the sewage are completed there will be no permanent relief for the affected area.

Queen's College, Belfast.

At a meeting of subscribers to the Better Equipment Fund of Queen's College, Belfast, held on June 2nd, it was reported that the sum of £29,633 had been up to the present subscribed to the fund, which, with interest received, made the amount altogether £30,040 11*s.* A sum of £2093 remains subscribed but not yet received. By the help of this fund the following additions to the equipment of the College have been made: a chair of pathology, a studentship in mathematics, a demonstratorship in pathology, a playing field for students, an organ, a lectureship in music, a library of music, a supply of radium, an assistant in botany, a lecturer in history, an assistant in modern languages, a biological laboratory, as well as minor grants in different departments. A motion was carried bringing under the notice of the Government the strong and increasing claims of Queen's College, Belfast, to more generous treatment by the State.

The Irish Medical Directory.

The new Irish Medical Directory has occasioned so much discussion that it may interest readers to know some facts as to its origin and reception. It would appear that last year's President, Mr. R. F. Tobin, at the annual general meeting on June 7th, 1904, suggested the issuing of an Irish Medical Directory and the committee of council at its first meeting, June 22nd, 1904, proceeded to put this proposal into effect, according to the following minute: "The President brought under the notice of members the advisability of publishing, in the form of an annual directory, the names of all medical practitioners in Ireland, distinguishing members of the association in heavier type, and moved: 'That a grant of £15 be made towards the preliminary expenses of the directory.'" The motion was seconded and carried. The secretary being unable (owing to his onerous duties) to undertake the bringing out of the directory the editor consented to see it through. The work was well advanced when it was discovered that Messrs. Churchill would object to their work being used for purposes of compiling another directory. As a result, a complete change in the mode of procedure was necessitated. Circulars were sent to branch secretaries and to every member of the Irish Medical Association with the object of obtaining information of their qualifications, &c., and when forms were not filled information was taken from the Medical Register. It was not possible the first year to go to the same trouble and expense in the case of non-members. Advertisements were secured to lessen the cost. The original grant for preliminary expenses was £15, while the cost of printing and binding the original edition of 3000 copies was £118 14*s.* 6*d.* The postage was £22 5*s.* 10*d.*, while the advertisements secured £107 3*s.* 9*d.* Copies were sent to every member of the association. So much for the origin of this medical directory, but when it came to the hands of the profession it aroused a great deal of bitter criticism, because: (1) as might be expected, its get-up and appearance suggested want of oversight and care; (2) the printing of members of the Irish Medical Association in black type made an invidious distinction between them and other medical men not members of the association; (3) of these black-typed members a disproportionate amount of space was given to some in comparison with others; and (4) those who are not members of the association are printed without any notice except their name and address, and not the least reference is made to their appointments, qualifications, or publications. I am glad to know that at a meeting of the council of the Irish Medical Association, held on May 3rd, a motion was carried "that no further edition of the Irish Medical Directory be issued until it has in every detail received the approval of the council." I really think if the Irish Medical Association would simply publish in its journal the list of its members nothing more is needed—a medical directory limited to Ireland is of little or no use to anyone.

At a recent meeting of the governors of the City Hospital [illegible] Cancer, Dublin, Mr. Tobin, [illegible]'s Hospital, was unanimously [illegible] the hospital in room of the [illegible]

June 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Subcutaneous Injection of "Sea Water Serum" in the Treatment of Tuberculosis.

AT the meeting of the Academy of Medicine held on May 23rd M. Troisier read for M. L. Fournol a note upon the use of subcutaneous injections of sea water in cases of tuberculosis. Together with M. Barlerin M. Fournol had prepared a sea-water "serum" which raised the blood pressure (*serum marin hypertonique*) and he had tried this on 24 patients under the care of M. Landrieux at the Lariboisière Hospital. Some of them had pulmonary tuberculosis in an early stage and others had old-standing tuberculosis of the bones. A marked improvement, both general and local, was observed in all the twenty-four. M. Fournol's results were so encouraging that the Academy decided to send a note of them to the Tuberculosis Commission.

The Galactagogue Properties of Lactagol.

At the meeting of the Obstetrical Society held on May 18th M. Legrand drew attention to the galactagogue properties of lactagol. This substance is a powdery extract of cotton seed which contains the galactagogue active principle of this plant. It is insoluble in water but may be given in milk in doses of three or four teaspoonfuls per diem. Given thus it increases the secretion of milk in a marked degree. M. Legrand has observed cases in which the leaving off or resumption of the drug coincided with a diminution or increase in both the quantity and quality of the milk.

Costal Pneumococcic Abscess bursting into the Bronchus.

At a recent meeting of the Hospitals Medical Society M. Boidin showed a patient who had been under the care of M. Widal. While apparently in perfect health and without any history of injury he was suddenly attacked with acute pain over the anterior extremity of the second rib on the left side. Twelve hours later there was marked œdema of the supra- and sub-clavicular regions on the affected side. The œdema increased until at the end of ten days an abscess began to point in the axilla. The temperature ran up and the patient suddenly coughed up a large quantity of pus which contained virulent pneumococci in an almost pure culture. After this the swelling and the expectoration rapidly ceased. There was no other sign of pneumonia and the patient quickly recovered. The case was evidently one of pneumococcic costal abscess bursting into the bronchus. M. Boidin considered that the costal abscess was the primary lesion and not secondary to a purulent encysted pleurisy of the apex.

Methods of Masking the Taste of Quinine.

In Algeria, where large quantities of quinine are dispensed, [illegible] drug is not given in cachets or made up into pills on the [illegible]re of economy. It is simply dispensed as a powder and [illegible] patient takes it in lemon juice. In the case of children, [illegible]ever, this method of dispensing it is impossible and at [illegible] meeting of the Therapeutical Society, which was held [illegible] May 24th, M. Yvon read some notes in which he said [illegible] he had endeavoured to mask the taste of quinine [illegible]eeping it away from the tongue. To do this he [illegible]oped it in a fatty body. A small quantity of [illegible]onate of sodium was added to neutralise the acids [illegible] might be present on the surface of the tongue [illegible] dissolve a small quantity of the quinine. He takes [illegible]ammes of precipitated quinine and ten grammes [illegible] of sweet almonds dissolved in ether, and makes this [illegible]aste to which are added a small quantity of alkali and [illegible]vouring agent, such as lemon or mint. Quinine pre[illegible]us can be swallowed quickly without any disagree[illegible]e and rhubarb can be made up in the same way.

Useful Hygienic Measures.

[illegible] Normandy Public Health Society has struggled for [illegible]rs to make the Rouen Tramways Companies forbid [illegible]ployés to separate the tickets distributed to [illegible] by moistening them with saliva. In Paris the [illegible]onductors on their own behalf have invented an [illegible] plan which consists of using a pencil with a piece [illegible]ber at one end to separate the tickets. They thus [illegible]ng on their fingers, a custom which they consider [illegible]

A Memorial to M. Tarnier.

A [illegible]orial to M. Tarnier was unveiled on June 1st. M. Bienvenu-Martin, Minister of Public Instruction, presided at the ceremony and the memorial, which has been erected by publi[illegible] of Paris [illegible] committee [illegible] some portio[illegible] it with the [illegible] form a part [illegible] Scellier of G[illegible] In the memo[illegible] M. Tarnier is [illegible] standing at [illegible] holding the i[illegible] *[illegible]euse* for the reception of [illegible] infants is shown at the side. The features of [illegible] master, seen in side-face, are admirably rendered, his meditative attitude being true to the life, and the sculptor has caught the expression of confidence and smiling good nature which was so characteristic of the original. The principal inscription gives his name with the dates of his birth and death: 1828–1897. On the base there is another inscription to the effect that the memorial is the tribute of colleagues, pupils, friends, and admirers to the merits of a great man who devoted his life to the preservation of mothers and infants. All Tarnier's great qualities of goodness and sympathy, his victories over puerperal fever, and his early work for the adoption of asepsis and antisepsis in obstetrics were mentioned in moving and grateful terms in the various addresses which were delivered, the successive speakers being Professor Brouardel, M. Reboillard, the Vice-President of the Municipal Council of Paris, the Prefect of the Seine, M. Pinard and M. Budin on behalf of the Faculty of Medicine and the Academy of Medicine, M. Mesureur on behalf of the Assistance Publique, and finally the Minister of Public Instruction on behalf of the Government.

Prophylactic Measures in Algeria.

The Minister of War has just decided that systematic endeavours to prevent malaria shall be made this year in the unhealthiest garrisons in Algeria. The larvæ of mosquitoes will be destroyed by the regular application of petroleum to stagnant water or by the drainage of such collections of water whenever possible. Patients suffering from malaria will be isolated in the infirmaries or hospitals in special apartments, the outlets of which will be protected by wire gauze so as to prevent the infection of mosquitoes which might subsequently propagate the disease. Persevering attempts will be made to destroy the malarial germ in the blood of patients and the men in good health will take quinine regularly as a prophylactic against inoculation by mosquitoes.

June 6th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Micro-biology of Syphilis.

Dr. Fritz Schaudinn, zoologist to the Imperial Health Office, and Dr. Erich Hoffmann, assistant in the University of Berlin clinic for venereal diseases, have announced in the *Deutsche Medicinische Wochenschrift* and at a meeting of the Berlin Medical Society that they have discovered a specific protozoon in primary chancre, in syphilitic papules, and in the enlarged lymphatic glands of syphilitic patients. They propose to name the newly discovered microbe spirochæte pallida. It is a delicate filiform organism varying in length from 4μ to 14μ and twisted spirally like a corkscrew, the number of turns being from six to 14. Spirochæte pallida is distinguished from all other species of that genus by the difficulty experienced in staining it and up to the present time it has been stained only with Giemsa's eosin blue solution. In eight cases of syphilis, of which a detailed account is given in the *Deutsche Medicinische Wochenschrift*, the organism was found in two patients in the inguinal glands which had been excised and in six patients in the juice obtained from the glands by puncture and aspiration. Of these cases six had a duration of only from four and a half to eight weeks and therefore had not yet developed secondary symptoms in the skin and the mucous membrane; the remaining two cases had a duration of from three to four months. Dr. Buschke ha[illegible] organism in the spleen of an i[illegible] syphilis and Professor [illegible] apes which had been [illegible] When the subject was d[illegible] Medical Society Dr. Ho[illegible] that he had found it in every case of primary chancre and ulcerated papules; he had also in 12 cases found it in the juice removed from specifically affected lymph glands, but it was absent in soft chancre. In the discussion Dr. Thesing said that it was very remarkable that the alleged spirochæte could be stained only by Giemsa's eosin solution and not by Romanowsky's method; he was of opinion that these organisms were in reality derived from the staining fluid which was a good culture medium for protozoa on account of the large proportion of dextrin present in it. The general tendency of the other speakers was to refrain from expressing a definite opinion.

Cerebro-spinal Meningitis.

At the last meeting of the Berlin Medical Society Dr. Westenhöfer read a paper on Cerebro-spinal Meningitis from a Pathological Point of View. He was a member of the commission sent by the Prussian Government to Upper Silesia for the purpose of studying the disease which has already been mentioned in these columns[1] as prevalent in that part of the empire. Dr. Westenhöfer had ample opportunity of carrying out researches on the nature of cerebro-spinal meningitis as no less than 29 post-mortem examinations were performed by him. He stated that the point of entrance of the virus was probably the nose and the naso-palatal cavity which were usually in an inflamed condition. It was remarkable that the entire lymphatic system was affected by the disease. As in childhood the lymphatic system was less resistant children were more liable to contract the disease than adults. In children suffering from affections of the lymphatic glands the disease was especially dangerous and it has been observed that if one of several children in a family had affected lymphatic glands he might contract the disease whilst the others remained in good health. In patients who had died within a few hours after the first appearance of the symptoms no affection of the meninges might be discoverable, the disease presenting only the phenomena of toxæmia. Dr. Kirschner of the Government Medical Department and president of the commission, said that the disease was less contagious than cholera and enteric fever and was not spread by contaminated milk or water but from patient to patient. The cause of the relatively small degree of contagiousness was that the meningococcus intracellularis, discovered by Professor Weichselbaum and considered to be the specific organism of the disease, was exceptionally liable to perish. On bacteriological examination of the cerebro-spinal fluid of 243 patients the meningococcus was found in 138, or 56·8 per cent.; agglutination tests were made with the blood in 420 cases and a positive reaction was obtained in 55·2 per cent. The meningococcus was found in the mucus of the nose in 23 per cent. of patients and in 9 per cent. of healthy persons in immediate contact with patients. It was very probable that the virus was spread by minute droplets of fluid as in tuberculosis, so that healthy persons should be on their guard when patients are coughing and should use prophylactic gargles.

June 6th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Death-rate among Negroes from Consumption in New York City.

A CONFERENCE called by the committee for the prevention of tuberculosis of the New York Charity Organisation Society to discuss the high death-rate from tuberculosis among negroes, the causes and effects of the disease, and the best means of combating and preventing it, was recently held in the assembly hall of the United Charities building, New York city. Dr. Andrew H. Smith was in the chair. A well-known lady, Miss Lilian Brandt, read the following statistics, showing the death-rate from consumption between the ages of 15 and 44 years for every 100,000 in 1900: Ireland, 428 per 100,000; Bohemia, 235 per 100,000; Scandinavia, 234 per 100,000; France, 221 per 100,000; Germany, 206 per 100,000; Scotland, 201 per 100,000; Canada, 200 per 100,000; United States (native born whites), 163 per 100,000; England, 151 per 100,000; Italy, 150 per 100,000; Russia, 131 per 100,000; Hungary, 113 per 100,000; and Poland 67 per 100,000. But the figures for negroes in the United States come out at 584 per 100,000. Dr. S. A. Knopf in the course of an interesting address made the following remarks: "Alcoholic intemperance will often lead to consumption. The dark rooms of the tenements are the breeding grounds of tuberculosis. Good food and proper living are excellent preventives. It can be cured, not by patent medicines, 'quacks,' faith curists, or Christian Scientists, but only by judicious use of fresh air, good food, and water baths inside and out." Dr. W. A. Brooks, a negro physician, asserted that the manner in which the negroes of New York herded together under the most insanitary conditions was mainly responsible for the prevalence of consumption among them. Motions were passed recommending that active steps should be taken to educate the negroes of New York city with regard to tuberculosis and that a committee should be appointed to coöperate with the committee on the prevention of tuberculosis of the New York Charity Organisation Society to bring about the desired results.

Sanitation in the Panama Canal Zone.

The *New York Sun* points out the surpassing importance of proper sanitation in the Isthmian Canal Zone. The article draws attention to the fact that the work of the canal sanitary department has been greatly hampered by red tape and officialism and states that no more competent man could have been placed at the head of the health department than Colonel Gorgas. The article ends by making an urgent plea that he may be given a free hand so that he may have the opportunity of as thoroughly cleansing the isthmus of Panama as he and his coadjutors succeeded in cleansing Havana. A New York engineer, Mr. Lindon Bates, has recently submitted to the president and Secretary Taft a new project for the building of the Panama Canal. Two of the essential features of this plan are that Lake Chagres and Lake Panama should submerge the deadly swamps around the terminal cities. According to Mr. Bates the carrying out of such a scheme must have most beneficial effects upon the health of the engineering and construction forces, and upon the residents of the cities for all time. There would be no stifling jungles, there would be the mosquito as a pest could be

The Harvey Society.

A new society, called the Harvey Society, consisting of laboratory workers in New York city, has recently been established under the patronage of the New York Academy of Medicine. Its purpose is the diffusion of scientific knowledge in selected chapters of anatomy, physiology, bacteriology, pathology, pharmacology, and physiological and pathological chemistry by the means of public lectures by men who are workers in the subjects presented. Each lecture is intended to represent the state of modern knowledge concerning the topic treated. It is hoped that through these lectures the common interests of research workers and the medical profession may be profitably cultivated. The fulfilment of the purposes of the society has been intrusted to the hands of the following committee: Graham Lusk (president), Simon Flexner (vice-president), George B. Wallace (secretary), Frederic S. Lee (treasurer), Christian A. Herter, S. J. Meltzer, and E. K. Dunham. The members of the society consist of two classes, active and associate members. Active members are laboratory workers in the medical sciences residing in New York. Associate members are such persons as may be in sympathy with the objects of the society and who reside in New York. The first course of lectures will be given on Saturday evenings during the winter of the years 1905–06 at the Academy of Medicine.

Defective Eyesight among the School Children of New York City.

At a recent meeting of the Society of Medical Inspectors of the New York city health department the result of the new system of physical examination of school children was discussed. Dr. John H. Cronin, chief of the division of school inspection of the department of health, read a paper in which he especially emphasised the bad sight of the school children of New York. According to Dr. Cronin the inspectors have found within the past few months that about 3 per cent. of all children in the schools have defects of vision interfering with the proper pursuit of their studies. Of these a large number have procured glasses. "This has already," says Dr. Cronin, "resulted in an improvement of the school work, as borne out by the teacher's reports. The reason so many children are found backward in their studies is because there are so many with physical defects, such as defective sight and hearing, who are unable to keep up with other children of their age and who retard the progress of the class."

---

[1] THE LANCET, May 20th, 1905, p. 1386.

Annual Statistics of the Roosevelt Hospital, New York.

The thirty-third annual report of the Roosevelt Hospital, New York city, has recently been issued. The report is for the year ending December 31st, 1904. The number of patients under treatment for the year was 4,326, larger by 380 than in the previous year. The daily average of patients was 182. The average length of stay of each ward patient was 15½ days and of each private ward patient rather more than 19 days. The daily average of patients was 455. 10,015 cases were treated in the emergency department, while the total number of visits to this department was about 20,000. 1897 operations were performed during the year. In the ambulance service the electric motors were given up and horses were used as formerly. There were 6719 calls upon the ambulance. 67,313 visits were made to out-patients. $179,573 (£35,934) were expended for the current expenses of the hospital, a smaller sum than that expended in 1903. The contributions for the year amounted to $42,000 (£8400). The permanent fund of the hospital has been increased by $30,000 (£6000) by the endowment of six beds costing $5000 (£1000) each.

Decrease of Cerebro-Spinal Meningitis in New York City.

The New York city death-rate for the week ended May 13th was 19·01, as against 21·57, the rate for the previous week. With regard to deaths from cerebro-spinal meningitis there were 88 compared with 110 of the week before. The cases of pneumonia resulting in death numbered 215.

Death of Dr. A. W. Rogers.

Dr. Alexander W. Rogers, the oldest member of the College of Physicians and Surgeons of New York, died on May 14th at Paterson, New Jersey. Dr. Rogers was born in Armagh, Ireland, in 1814 and came when young to the United States with his father. He graduated from the College of Physicians and Surgeons in 1836.

May 30th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Milk-supply of Indian Cities.

THE dangers of impure milk are very prevalent in the large cities of India. The retail sellers admit watering the milk and the native population look upon it as a recognised custom. The water added is not necessarily the filtered or otherwise pure water of the city. The byres where the cows are kept are for the most part very limited in space, the animals are crowded together, the floors are horribly filthy, and the udders and flanks of the cows are seldom or never cleaned. The milkers are dirty in their habits, as they do not wash their hands, frequently dip their hands into the milk, and are indifferent about dirt on the udders. Add to all this the use of dirty pails and the custom of floating straw on the surface of the milk and an idea can be formed of the stuff which is distributed as milk to the great mass of the people. There are a few wholesale dealers who take precautions to insure as far as possible a wholesome-supply but the above conditions are the prevalent ones. The question of the milk-supply is being discussed in Calcutta and the evils in that city are about as bad as they can be, but the proposals of the health officer afford neither an immediate nor a drastic remedy. The offer of a certificate on fulfilling certain conditions is absolutely useless, as prosecutions already fail to effect any appreciable improvement and no further proposal is suggested. The authorities seem to fear the prospect of the milch cattle being taken out of the town and are equally timid about undertaking the milk business themselves. Nothing, however, could be possibly worse than the present state of things and it is only the almost universal custom of boiling the milk which probably saves the situation.

The late Outbreak of Small-pox in Bombay.

A severe outbreak of small-pox in Bombay during the first quarter of the year necessitated the prosecution of numerous persons for wilfully doing things tending to the spread of the contagion. The custom of taking patients in all stages of the disease in public conveyances to the temples for special religious rites is particularly dangerous but active measures have temporarily stopped this pernicious practice. No attempt was made forcibly to remove patients to the hospital, but more than 1100 cases were admitted and it is estimated that about 2000 other cases occurred. As the mortality of the hospital cases was only 25·6 per cent., whereas the mortality of those not removed to hospital is returned at 62·8 per cent., the inference is obvious that a very large number of cases failed to come under observation because the benefit of hospital treatment can hardly be credited with such a large reduction in case mortality. The health officer asks for more hospital accommodation. In Calcutta there is no municipal hospital at all. In Bombay there are 12 horse ambulances for infectious cases, whereas I hear that there is not a single one in Calcutta. In Bombay they prosecute the owners of public conveyances for carrying infectious cases. In Calcutta infectious cases are freely moved about in the public vehicles which are more or less disinfected at those hospitals which receive infectious cases. This contrast between the methods adopted in the two cities might be extended. The provisions in Calcutta for dealing with an outbreak of infectious disease such as small-pox are of the scantiest. Even cases of plague have to be taken to the general hospitals where they are put in isolated wards, but in one hospital cholera cases and plague cases are mixed up together and in another hospital cholera cases are put in the general ward.

The Plague Epidemic.

The plague mortality throughout India for the week ending May 6th is returned at 52,253, a decline of 4478 from that of the previous seven days. In the Punjab, however, the mortality rose from 15,710 to 30,909. Elsewhere the decline was general. The United Provinces returned 12,909 deaths, against 28,728 in the previous week; Bengal, 2436, against 4733; Rajputana, 3358, against 2298; Bombay Districts, 1952, against 2378; Burma, 90, against 147; Central Provinces, 77, against 116; Hyderabad State, 68, against 95; Central India, 24, against 59; Mysore State, 26, against 51; and Madras Presidency, 22, against 49. The rapid decline in Rangoon is very satisfactory and it is to be noted that the authorities have been remarkably active and successful in destroying rats—some 50,000 having been secured.

May 20th.

Obituary.

JAMES MURPHY, M.A., M.D., M.CH. DUB., M.D. DURH.

WE regret to announce the death of Dr. James Murphy, who, although he lived in Sunderland, had associations, professional and social, over an area very much wider than that of Wearside. It is not too much to say of Dr. Murphy that he was one of the ablest surgeons of his generation, as he was one of the most genial and kindly of men. The news of his untimely death will be received by very many members of the profession with profound sorrow. The sad event occurred at Dr. Murphy's residence, 6, Thornhill-crescent, Sunderland, on Tuesday night, May 30th. The deceased gentleman was in his fifty-second year. He had been following his professional duties at the end of the previous week and as late as Friday, May 26th, he gave evidence in a compensation case at the Sunderland county court. Dr. Murphy was out driving on May 27th when he caught a cold; pneumonia supervened and death ensued with extreme rapidity.

Dr. Murphy as a surgeon particularly skilled in obstetrics and gynæcology had won a reputation that was not confined to the North of England but extended throughout the land. He was born in the year 1853, and was the son of the late William Chapman Murphy, M.D., and a nephew of the Right Hon. Justice Murphy of the Supreme Court of Ireland. He was a native of Ballinahow in the county of Tipperary, and preserved all the amiable characteristics of an Irishman throughout his life. He was educated at Trinity College, Dublin, where he was in his year honourman and prizeman in science. Subsequently he studied in Edinburgh, London, Leyden, and Paris, and entered upon his profession thoroughly equipped. He became M.B., I.Ch. of the University of Dublin in 1874 and was house urgeon to the late Sir William Stokes of Dublin. In 1874 e was appointed house surgeon to the Sunderland Inrmary but resigned in 1876 and settled in private practice ı Sunderland. He became M.D. at Dublin in 1877, L.R.C.S., .M. of Edinburgh in 1878, and M.D. of Durham (*ad undem*) in the same year. In 1878, also, Dr. Murphy was ppointed lecturer in botany in the College of Medicine, lewcastle-upon-Tyne. He was afterwards appointed ecturer on biology and was subsequently transferred to he chair of medical jurisprudence, which he held till his eath, as well as the office of assessor in materia medica and herapeutics.

In 1890 Dr. Murphy was vice-president of the Section of)bstetrics and Gynæcology at the annual meeting of the 3ritish Medical Association in Birmingham, and in the ollowing year, when the Association met in Bournemouth, ıo delivered the opening address in the discussion on)iseases of Women. In 1893, during the meeting of the ıssociation in Newcastle he was president of the Section of)bstetrics and Gynæcology. Dr. Murphy had been for over 0 years a frequent contributor in the Sections of Surgery and)iseases of Women of the British Medical Association and ıad read many papers before the local medical societies. He was president of the Northumberland and Durham Medical Society for some two years, and was president also of the North of England branch of the British Medical Association and a member of the central council of the Association of which he was a most frequent attender. He vas an honorary member of the Société de Médecine Pratique de Paris and also of the Deutsche Gesellschaft fur Gynäkologie, Berlin. Dr. Murphy delivered the inaugural ıddress at the Durham University College of Medicine, 1881-82.

Dr. Murphy, after he resigned the office of house surgeon ıt the Sunderland Infirmary, was made honorary surgeon ınd held the position till his death. He was an ex-vice-president of the British Gynæcological Society. He wrote a good deal and always concisely and ably, his publications ıncluding the following: "Case of Divided Uterus"; "Pilocarpine in the Treatment of Puerperal Eclampsia"; "Treatment of Placenta Prævia, with Notes of 47 Cases"; "Notes on a Case of Porro's Operation"; and various other articles on surgery and gynæcology. Dr. Murphy was a broad-minded man and physically very robust. He was devoted to yachting and was a warm and discriminating patron of the drama. He was twice married and is survived by his widow and daughter.

HERBERT WILLIAM BROWN, M.B. LOND.

THE death of Dr. H. W. Brown from typhoid fever at Cairo on May 12th has removed one of the younger members of the profession who could ill be spared. Several resident appointments at Guy's Hospital and a year's good work at the London School of Tropical Medicine were a fitting preparation for the post of resident medical officer at Kasr-el-Aini Hospital which Dr. Brown held at the time of his death. His sound judgment, devotion to his duty, and kindliness of manner made him greatly respected and esteemed by his colleagues and his early death at the age of 27 years is regarded by them not only as a direct personal loss but also as a loss to the profession, in which he gave promise of a most brilliant career.

Medical News.

TRINITY COLLEGE, DUBLIN.—At the examination held in Trinity Term the following candidates passed in the subjects indicated:—

Final Examination in Surgery.—Henry H. A. Emerson, Cecil A. Boyd, Charles R Morris, Howard English, William F. Samuels, John Murdoch, William G. Harnett, Charles C. Williams, Thomas T. H. Robinson, Wilfred L. Myles, Henry H. White, William C. MacFetridge, Francis J. Usher, and John Chambré.

M Ch. degree.—Paul Carton, M.D., and Samuel Synge (clk.), M.D.

MEDICAL MAGISTRATES.—The name of Mr. Alfred James Lowe of Home Lea, Boothstown, was on June 1st placed on the commission of the peace for the county of Lancaster.—Mr. J. Morgan Evans, L.R.C.P. Lond., M.R.C.S. Eng., of Llandrindod Wells, has been placed on the commission of the peace for the county of Radnor.

PREVENTION OF INFANTILE MORTALITY.—On June 5th a conference was held at the town hall, Pancras-road, London, N.W., under the presidency of Dr. R. M. Beaton, L.C.C., when the question of the prevention of infantile mortality by the improvement of the health of mothers and of the feeding of sucklings was discussed. A letter was read from Sir Lauder Brunton advocating pure fresh milk rather than sterilised milk as infants' food. Sir William Broadbent dwelt on the important bearing which infantile mortality had upon the physical deterioration of the race and said that the whole future of thousands of children depended upon the first few weeks of life. Dr. Herbert R. Spencer, Mrs. Scharlieb, Professor A. Macfadyen, Dr. H. R. Kenwood, and Dr. Dudfield took part in the discussion and several important resolutions were adopted affirming the desirability of the instruction and care of mothers, the early registration of births, the appointment of women inspectors, the importance of breast feeding, and the danger of premature weaning.

OPENING OF A NEW CONVALESCENT HOME AT LITTLE COMMON, BEXHILL.—On May 25th the board of management and a number of friends and supporters of the institution visited the new men's home of the Metropolitan Convalescent Institution at Little Common, about three miles from Bexhill. The buildings when complete will accommodate 118 patients but owing to lack of funds the central portion only of the building has been completed, with 71 beds for patients. When sufficient money is forthcoming an east and a west wing will be added. The buildings are fitted with the most modern sanitary and electrical appliances. The Metropolitan Convalescent Institution was founded in 1840 and now maintains four homes, containing 555 beds, to which every year nearly 7000 patients are admitted free upon discharge from hospitals or after illness at home. The address of the London office is 32, Sackville-street, Piccadilly, W.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, MAY 31ST.

Human Deaths from Glanders.

[illegible] whether, having regard to these circumstances, he would take the necessary steps to have the mallein test compulsorily applied to all in-contact animals in case of outbreaks of glanders and to provide a full veterinary inspection and the application of the mallein test in the case of horses imported from Australia or any country in which glanders was prevalent or suspected.—Mr. FELLOWES answered: I have received from the London County Council full inform[illegible] as to the result of its inquiries into the regrettable circum[illegible] it is a [illegible] of Aus[illegible] affecte[illegible] more [illegible] London [illegible] Order in the direction indicated is a subject which is receiving my careful consideration, but there are difficulties, both administrative and financial, in the way of the compulsory adoption of the mallein test in connexion with outbreaks of [illegible] am [illegible] any [illegible] inı- [illegible] o in- [illegible] ıs of [illegible] good [illegible] man [illegible] hich [illegible] deaths from glanders [illegible] a connexion was traced to outbreaks of that disease in horses.

MONDAY, JUNE 5TH.

Names Struck off the Medical and the Dental Registers.

Mr. WEIR asked the Home Secretary whether in view of the fact that during recent years 20 names had been struck off the Medical Register for infamous conduct in a professional respect and 12 res[illegible] n the Dental Reg[illegible] would state the na[illegible] those whose nam[illegible] could [illegible] cated; hardly specify the offences [illegible] and, as they have been restored to the register, this would merely give unnecessary pain to individuals without serving any useful public service.

Lunacy Return.

Mr. CHARLES HOBHOUSE asked the Home Secretary whether the return granted in 1904 relative to the expense of lunacy was yet ready and when it would be published.—Mr. AKERS-DOUGLAS said: This return, the preparation of which has been exceptionally difficult, is now in the printer's hands and will, I hope, be published shortly.

Physical Deterioration.

Mr. WEIR asked the Lord Advocate whether the Secretary for Scotland had yet considered the expediency of issuing to parochial medical officers, sanitary inspectors, and inspectors of poor, leaflets containing the opinions of the Committee on Physical Deterioration relative to ventilation and the bringing up of young children with a view to the dissemination of information on these subjects.—The LORD ADVOCATE answered: The Local Government Board is taking steps to ascertain how far it is practicable to issue leaflets on the lines suggested by the honourable Member.

TUESDAY, JUNE 6TH.

Direct Representatives on the General Medical Council.

Mr. WEIR asked the Home Secretary whether in view of the fact that under Section 7 of the Medical Act of 1886 the representation of medical practitioners on the General Medical Council was confined to three representatives for England, one for Scotland, and one for Ireland, and that during the interval of 19 years medical practitioners had increased in number in England alone by 7000, the General Medical Council had considered the expediency of representing to the Privy Council the desirability of increasing the number of representatives of medical practitioners on the General Medical Council as provided for under Section 10, Subsection (*c*), of the Medical Act.—Mr. AKERS-DOUGLAS replied: I am informed that this question was considered by the General Medical Council last month and on no less than six other occasions during the previous 15 years, but that each time the decision of the Council has been that it is inexpedient to make any representation to the Privy Council.

SELECT COMMITTEE ON REGISTRATION OF NURSES.

The Select Committee of the House of Commons which is consider- g the question of the registration of nurses heard further evidence Tuesday, June 6th

ady HELEN MUNRO-FERGUSON, replying to the Chairman, Mr. J. TENNANT, said she was a vice-president of the Association Promoting the State Registration of Nurses. She did not think the ent condition of things was satisfactory to the employing public. certificates issued by the various hospitals varied in value and the ic were unable to distinguish between their merits. Not the training but the examinations varied and it would be dvantage to have coördination. A certificate of the Central l would indicate to the public that that board had satisfied itself he holder was duly trained and had received a good character the matron of the training school. Many hospitals kept no s and many of the nurses who wished to go to the South African itration Camps with the Scottish contingent could not be d in the absence of such records, although they were qualified. ation would level up the country hospitals She did not think l be at all impossible for the poor in rural districts to secure the of fully trained nurses In Scotland they had many Queen's fully qualified, in the rural districts. She would be against wo classes of nurses. Cottage nurses, she pointed out, were certified midwives and had the status of their own register. led to the proposal of a Local Government Board committee in that the poor-house nurses in the absence of a standard should yllabus of training and an examination at Edinburgh or nd proceeded to state the various classes of the community h nurses were drawn. Of 143 nurses in one Scottish hospital he daughters of clergymen, 35 of professional men, 50 of six of clerks, 32 of farmers, and two had been in service.

C. HOBHOUSE. She did not want cottage nurses to be n the belief that they were fully trained and qualified igh she personally had no objection to them practising as

Notes, Short Comments, and Answers to Correspondents.

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST.

THE two letters which follow require little comment:—

122, Clapham-road, London, S.W., May 4th, 1905.

The Clerk to the London County Council.

DEAR SIR,—I shall be obliged if you will inform me at your earliest convenience the information I want to the following queries:—1. Mr. Troutbeck (after Dr. Freyberger has been sworn), addressing Dr. Freyberger, says: "You are the pathologist appointed by the London County Council?" Reply: "Yes." Is that a correct statement of fact? 2. How many inquests have been held by Mr. Troutbeck for the 12 months ending the financial year, and of these how many post-mortem examinations have been given to Dr. Freyberger? And as a corollary how many inquests have there been which entailed a £3 3*s.* expense—i.e., to pay for the attendance of Dr. Freyberger and the medical man called to the case? 3. Was it agreed between the London County Council and Dr. Freyberger that the fee per case for this special pathologist should be £2 2*s.*? I am, yours obediently,

(Dr.) W. PIERCY FOX.

LONDON COUNTY COUNCIL.
County Hall, Spring-gardens, S.W.,
May 31st, 1905.

SIR,—The Public Control Committee of the Council have considered your letter of May 17th, 1905, on the subject of the employment by Mr. Troutbeck, coroner, of Dr. Freyberger, one of the 18 pathologists nominated by the Council to make post-mortem examinations and to give evidence in special inquest cases.

With reference thereto I have to state that the Council is not in a position to insist that a coroner shall, when examining a witness at an inquest, conduct such examination in any particular manner, and that any complaint as to the conduct of a coroner should be addressed to the Lord Chancellor.

In reply to your request for particulars as to the inquests held by Mr. Troutbeck, I have to inform you that during the year 1904 Mr. Troutbeck held 926 inquests and engaged the services of a special pathologist (Dr. Freyberger) in 450 cases, in 168 of which additional medical witnesses were called.

With regard to the fees payable, I have to inform you that the special pathologists nominated by the Council to make post-mortem examinations and to give evidence in special inquest cases were so nominated on the understanding that the fee would be £2 2*s.* per case. I am, Sir, your obedient servant,

G. L. GOMME, Clerk of the Council.

Dr. W. Piercy Fox, 122, Clapham-road, S.W.

From the letter of the Clerk of the Council it would appear that Dr. Freyberger received, through Mr. Troutbeck, from the public £945 in fees during the year 1904. Frankly, we do not think his services are worth the money. We have chronicled inquests where Dr. Freyberger has been engaged when no special pathologist could, it appeared to us, be required, while we are a little at a loss to understand on what grounds Dr. Freyberger is regarded as a special pathologist, able to give the coroner assistance that could not be given to him by any practitioner. We learn from the Medical Directory that he has been "selected for London inquests," but after what ordeal and following upon what competition?

THE COUVADE.

To the Editors of THE LANCET.

SIRS,—With reference to the request of your correspondent for any local traditions as to illness of the husband during the pregnancy of the wife, I met with a case of tuberculous enteritis about a year ago in Bristol which was at first neglected by the patient and his friends because, as they said, they thought he was "suffering for the missus," who was advanced in pregnancy. I have met with no other instance of the belief in Bristol. In Dahomey it is, or was, the custom for a chief to retire to bed for some weeks during the confinement and puerperium of his wife. I am, Sirs, yours faithfully,

June 6th, 1905. X.

⁂ The superstition is widespread.—ED. L.

DANGEROUS HAT-PINS.

IN an annotation which appeared in THE LANCET of April 22nd last p. 1080) we stated that "it ought to be possible for an ingenious milliner to devise some less dangerous method of fixing on the hat." Our remarks having been seen by the *Alexandra Agency of Argyll-place, London, W.*, they have sent us a specimen of their patent double-headed safety hat-pin. This pin consists of an ordinary hat-pin, except that it is somewhat longer and more flexible than some of those in use, especially by many women of the poorer class. On the blunt end of this pin is fixed a knob of about the size of a Barcelona nut and on the pointed end is a knob made to match the other knob as nearly as possible, but the knob on this end of the pin is removeable. The removeable knob has a small tube running almost through the centre and this little tube or sheath apparently contains some hardened viscous substance of the nature of gutta-percha. The pointed end of the hat-pin after adjustment through the hat is sheathed in the knob. There seems to be no difficulty—to ladies, at all events—in the sheathing process whilst the pin is in the hat on the head and the adjustable knob certainly affords protection from the dangerous point. If the removeable knob were studded with real diamonds and other stones there would be some fear felt of losing the knob in gusty weather, although we must say that we had to agitate the pin violently to shake off the knob. We think, however, that if the knob were screwed on to the pin or if some other device were employed giving a mechanical grip, it would be an improvement. We have also noticed that the great flexibility of the shaft of the pin prevents it from penetrating several folds of cloth as readily as do some of the stiffer-stemmed and cheaper pins, such as the common pins with black knobs.

AN OLD LANCET CASE.

To the Editors of THE LANCET.

SIRS,—Will you permit me to thank Mr. Edward A. Piggott for his information *re* "Savigny & Co." and "Pratt," from which it is quite clear that the lancets, though not absolutely modern, were not the original occupants of the case. I am, Sirs, yours faithfully,

June 7th, 1905. PROVENANCE.

TO DEADEN SOUND.

To the Editors of THE LANCET.

SIRS,—I have a patient who suffers at times from insomnia. He believes that if he could hear of some comfortable apparatus to wear at night to keep out the noise of trains, &c., it would be of great benefit to him. I should be much obliged if any of your readers could tell me of any satisfactory instrument for this purpose.

I am, Sirs, yours faithfully,

June 7th, 1905. J. S. R.

THE ADMINISTRATION OF ETHYL CHLORIDE.

To the Editors of THE LANCET.

SIRS,—I should be very much obliged if any of your readers would send me notes of any cases in which the administration of ethyl chloride has proved fatal. The advantages of the anæsthetic are obviously very great. Unsatisfactory results are not always recorded in medicine. I am, Sirs, yours faithfully,

Ullswater, near Penrith. ARTHUR G. WILKINS, M.B. Vict.

NOTES ON THE SORBONNE.

To the Editors of THE LANCET.

SIRS,—In your review of the pamphlet under this heading in THE LANCET of June 3rd, p. 1503, there is a slip as to the date of the founding of the College. *The Founder was born* in 1201 and *the College was founded* in 1252. Since the publication of the pamphlet Mr. Dennis Lane has joined the majority and the pamphlet, with plan of the dome, can be had (price 4*d.* post free) from

Yours faithfully,

Wimbledon, S.W. J. A. RANDOLPH.

◆

L.R.C.P. & S. Ed.—If the rules of the hospital do not forbid the procedure we cannot see how the medical man's conduct is to be called in question. A medical officer to a hospital, as a rule, consults with other members of the staff of the hospital, and our correspondent does not state whether this proceeding has been neglected. The circumstances are given in his letter so briefly that we are unable to make a more definite reply, but it must be remembered that customs at home and customs in the colonies are not always similar.

Jim.—1. The degrees of the University of Sydney are registrable in the Colonial List after compliance with certain regulations. The registered practitioner enjoys all the usual privileges. 2. The practice varies greatly at different colonial universities and in different curricula towards partly qualified students of the home universities. The registrar of the university should be asked. 3. It would be unadvisable to go to the colony in such circumstances unless a definite arrangement is made with an employer.

R. H.—It is not usual in this country to claim the position of a specialist on the door-plate in the way which our correspondent suggests. A man should not appear before the public as a specialist unless he has proper reasons for claiming the position, in which case his patients will be sent to him by medical men who will appreciate the value of his claim and will not want to be reminded of it by a door-plate.

M.B.—It is difficult in these days for a medical man in a prominent position to escape such unfortunate publicity. We do not like to make adverse comments upon such paragraphs as our correspondent has sent us unless we know that the subject of the paragraphs has inspired the information.

X. Y. Z.—Ozonising tubes may be obtained from almost all dealers in electrical apparatus. The best for our correspondent's purpose would probably be Andreoli's, sold by Messrs. Allen and Hanbury, 48, Wigmore-street, London, W.

Surgeon has opened a large question. The work done by cottage hospitals varies much in different parts of the kingdom. The question is too large a one for a brief answer and we will return to the subject.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information,
d addresses of

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

A Lecture
ON THE
INDICATIONS FOR OPERATION.

Delivered at the Medical Graduates' College and Polyclinic, London, on May 11th, 1905,

By RUTHERFORD MORISON,
F.R.C.S. Eng. & Edin.,
SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

GENTLEMEN,—To prevent sepsis, to arrest hæmorrhage, or to remove a focus of disease—one or other of these things is, in the majority of operations, the purpose of the operator.

PREVENTION OF SEPSIS.

As an illustration of this, the following case may be given of operation after injury to the brain. One afternoon I received by telephone a message asking me to go to see a young man, aged 18 years, who had injured his head and who still bled but not profusely. The message was not urgent; I was to go as soon as convenient. On my arrival he was in the nursery with some younger brothers and demonstrated on the remnants of a toy cannon what had happened. In firing the cannon it exploded and something struck him in the forehead. Part of the cannon was missing. There was a small incised wound on the upper part of his forehead on the right side still slowly oozing. If I have not already conveyed the impression that he appeared to be no worse for the accident let me say now that he was able to walk along with me to a private hospital without help or difficulty and to run upstairs. I did what we *always* do as a matter of routine—introduced a sterilised probe into the cleansed wound. A finger is the best probe but this wound was quite small. On introducing the probe I found to my horror that it went through a hole in the skull. To prevent wound infection I decided at once to operate—to trephine. On removing a disc with the trephine a hole was found in the dura mater and on introducing a probe through this small pieces of bone and the breech of the cannon were discovered in, and removed from, the right frontal lobe. After suture of the dura mater the wound was packed with gauze and dressed. Ten days later the wound, which showed no sign of infection, was reopened and the skull defect was repaired by bone grafts. He was afterwards passed into the Yeomanry as sound and distinguished himself in the South African war.

In contrast with the above case, which illustrates the value of probing, I will describe another in which probing was neglected. The most curious feature of this very curious case is that the results which might well have been expected from this neglect did *not* happen. A boy, riding on a hay-cart and carrying a pitchfork, fell and was carried home unconscious. A large wound on the right side of the scalp and face was cleansed and stitched and subsequently healed by first intention. Two years afterwards, when the boy was about 12 years old, the wound began to reopen. A small abscess formed and healed and then, after a few months, a black object, *protruding about one-eighth of an inch, came through the skin.* At the Newcastle Infirmary he was seen by my house surgeon, Dr. J. W. Heslop, who easily pulled out with his finger and thumb a piece of hayfork four and a half inches long. It had apparently transfixed the antrum of Highmore and crossed the back of the naso-pharynx to the opposite side of the face. The boy suffered no ill-effects from its removal and walked away to the photographer's.[1]

The most necessary and the most successful operations are, as I have reminded you, performed for the prevention or for the arrest of sepsis. It is the best reason to be urged in favour of an operation that its object is to prevent or to arrest blood poisoning. Take the question which has been discussed *ad nauseam*, when to operate in cases of appendicitis. Operation is demanded when the risk of peritoneal infection is manifest. There is no other definite indication for operation. In cases of "appendicitis" of the type which allows its possessor to attend business regularly and which never interferes with a dance there is grave doubt whether the removal of the appendix is useful or even justifiable. But in cases that commence with acute pain and vomiting and are attended by inability to rest, elevation of temperature, quickening of pulse, tenderness and rigidity of the abdomen, the sooner operation takes place the better. When some doubt has been felt at first, none should remain at the end of 24 hours. Every case in which *all* symptoms and signs are not improved in that time requires operation; it is not enough that there may be betterment in some of them. This has been pointed out by my colleague, Mr. W. G. Richardson.[2] A rule of immediate operation in acute cases would prevent much prolonged illness from abscess and many deaths from general peritonitis, but in the peritoneum, as elsewhere, septic inflammation which has started may be impossible to arrest and when once it has been fully established operation frequently does more harm than good. The same truth may be recognised in other abdominal emergencies. If, for example, a ruptured gastric ulcer is not recognised till peritonitis has been established the patient had probably better be left alone. The chief object of the operation is to prevent or to arrest peritonitis; the repair of the ulcer is only a part of this.

It is no less true of acute cases of intestinal obstruction than of these more generally recognised examples that the most frequent cause of death is blood poisoning. Early in every acute case of intestinal obstruction that I have had the opportunity of observing it was possible to make a diagnosis by noting the cries of the patient in response to the severe spasmodic pain and by discovering increased peristalsis which could be seen, or heard, or felt. In these cases, if they are left alone or treated medically, the prognosis is very bad; not less than 80 per cent. die, while to do radical operations when the small intestines are distended and paralysed by septic contents is usually to court disaster.[3] These cases require prompt decision. I have elsewhere[4] urged the importance of early operation. A few hours of delay may make the difference between recovery and death. Additional experience has confirmed the results I then recorded and proved that the mortality of early operations is comparatively low—not more than 10 per cent. When the intestines are distended my rule has been to do enterostomy through the smallest possible opening with the object of arresting blood poisoning and at a later stage if the patient survives to complete the operation. The danger, however, should have been foreseen and operation done to prevent sepsis at an earlier stage.

The following cases illustrate the danger of delay in operating in cases of kidney stone and gall-stone respectively. A few days ago I operated upon a patient very ill with a large swelling in the left side of the abdomen. He gave a history of 20 years' discomfort and occasional pain in the left loin. There was abundant pus in the urine which was found to come from the left kidney, that from the right being healthy. Roentgen rays showed a definite shadow in the position of his left kidney. I opened the kidney, from which a large quantity of pus escaped, and removed a large branching stone from the calyces. The patient is doing well but will only recover after a serious and prolonged illness with either the complete loss of the left kidney or much damage to it. Roentgen rays would have shown the stone before it caused septic changes in the kidney; its removal then would have been safe and satisfactory.

The same day I operated upon a patient who had gall-stones. There was a history of more than one year's duration that left but little doubt as to the diagnosis of gall-stones. In addition his liver and spleen were large and hard and his kidneys were defective, conditions attributed to prolonged liver sepsis secondary to gall-stones. This view was based upon the fact that at least once a week he had a violent rigor followed by vomiting, a high temperature, delirium, sweating, and great prostration. The diagnosis was confirmed by operation and subsequent post-mortem examination. The liver was in an advanced stage of cirrhosis, the common bile-duct was so much dilated as to resemble the small intestine, there were a large number of stones in the ampulla of Vater and elsewhere in the common duct, the ducts throughout the liver were much dilated, and the gall-bladder was packed with stones and had leaked into an abscess of the liver underlying it which contained many stones. The kidneys were much diseased.

---

[1] Journal of the Northumberland and Durham Medical Association, October, 1904, p. 357.

serve as an excuse for the neglect of the earliest possible operation.

[4] THE LANCET, Jan. 31st, 1903, p 279.

An early operation would have prevented all this mischief. There are far too few operations done for gall-stones, not for those cases which have advanced so far as the one just described and in which the propriety of operation is very questionable indeed, but for cases in which the gall-stones are still confined to the gall-bladder. I have fully expressed my views on this subject in previous papers,[5] and shortly summarised they are: that gall-stones may, like the [illegible] kidney stone, remain *in situ* for [illegible] causing symptoms; that the symptoms of gall-stones are only found when infection of the gall-bladder (sepsis) is superadded, and that then they become a serious possession and demand operation for their removal. I pointed out more than ten years ago[6] that gall-stones first show their presence by attacks of "spasms" which are likely to be ascribed to stomach troubles; this fact has now been generally recognised. Post-mortem examinations have proved to me that death not infrequently occurs from gall-stones which have escaped recognition. More opportunities for pathological research in the post-mortem room would convince all unbelievers. In the later stages a large percentage of cases die as a consequence of the operation and of their enfeebled condition, while others are not cured because it is impossible to remove stones from all parts of the liver and liver ducts. When the sepsis and stones are limited to the gall-bladder, operations are safe and easy and satisfactory; when stones have escaped into the ducts and have caused liver sepsis, operations are difficult and dangerous and unsatisfactory.[7]

The fact that mouth sepsis, ear sepsis, and throat and nose sepsis are a menace to health and life is not even yet sufficiently recognised, or at least if it is the knowledge is not sufficiently acted upon. To remove all of these conditions should be regarded as a necessity, and if their removal, as it sometimes does, demands a serious operation or operations these must be faced. No patient should be left with a septic focus if by any reasonable possibility it can be removed. It is only because the dangers of such foci are frequently obscured and delayed that their connexion with serious illness has not been more often proved. It is often even now said of persons with discharging ears that the discharge does no harm and has lasted for many years without result. Every surgeon knows the mortal consequences of middle-ear suppuration and does not hesitate at any measure which promises to arrest it; there are other forms of chronic suppuration elsewhere not less deadly.

ARREST OF HÆMORRHAGE.

The surgical rule is, to *see* the bleeding point in order to arrest the flow from it successfully; its importance has not been exaggerated. To comply with it may, as pointed out by Guthrie in his graphic commentaries, require a serious operation, but the advantages to be derived from it were for ever made clear by the relation of his cases. Recent surgical advances have only strengthened his arguments. Under this heading I will mention only a few points that have specially interested me.

Secondary hæmorrhage after injuries or operations is now an uncommon event, for it results from sepsis and this we usually succeed in preventing, and possibly because of the comparative rarity of its occurrence treatment may not always be prompt and decisive. It is often readily arrested by a pad over the bleeding point and a bandage, but recurs a few days later. If it does the bleeding point should be *seen* and the bleeding vessel should be firmly secured. This may involve a considerable operation but that should be no deterrent. The fact has been strongly impressed upon me that hæmorrhage which has more than once recurred is almost certain, sooner or later, to lead to a fatal result unless boldly attacked.

Some years ago it appeared to me probable, arguing from this analogy, that hæmorrhage from a gastric ulcer if it recurred was likely to proceed to a fatal issue without operation, but a larger experience has taught me that this is an exception to the rule. It is, however, probable, in spite of the difficulty of finding the bleeding point, that in cases of recurrent hæmorrhage from the stomach the safest course is to operate.

The symptoms and signs of hæmorrhage into the abdomen demand immediate operation. It would scarcely have seemed necessary to me to mention this but for a recent experience. Twice within the last six months I have been asked to operate for ruptured ectopic gestation on patients dangerously ill and have found the abdomen "full of blood." In one patient the practitioner in attendance had recognised the case so early as to diagnose ectopic gestation before rupture, strong evidence of his capacity and zeal. He followed the rupture of the sac and watched the formation of a localised hæmatocele. Three weeks later, after a sudden seizure, the operation was performed. The second case had a similar history but no diagnosis had been made till the hæmatocele stage. In both the abdomen was "full of blood." Each of the capable gentlemen who reported these cases told me the same story—viz., that they had been guided to the course they had adopted and had been led to defer operation by reading a recent discussion on the treatment of hæmatocele resulting from ectopic gestation. The outcome of this discussion by some of the greatest authorities on the subject was the conclusion that a large percentage of cases can recover without operation. It is, however, impossible for the greatest authorities to make a prognosis as to which cases will recover if left alone, while, on the other hand, surgeons generally recognise that death after operation is th[illegible] in neglected cases. Operation for the [illegible] of hæmorrhage should therefore, I consider, follow the diagnosis of ectopic gestation in the present state of our knowledge. As an answer to the question, "When would you operate?" I have given you these general indications, danger of sepsis or the presence of hæmorrhage, as the two most important guides in the decision of the question.

I will now proceed to refer to certain other problems of surgery in which the question, "When to operate," is also of vital importance.

ABDOMINAL WOUNDS.

One of the "lessons of the South African war" was to leave wounds—punctured wounds at least—of the abdomen alone, and the statistics offered in support of this position and the experience of the most competent army surgeons are overwhelmingly in support of it. The same rule applied in civil practice ends in disaster. It [illegible] *no wound of the abdominal wall must* [illegible]*ploratory operation.* It is surely needless to say that by this I do not mean to say the abdomen should be opened but that the track of the wound should be followed to the end. The relation of a case will emphasise the importance of this better than anything I can say.

At the end of a morning's work I met a man going into the infirmary as I was going out. He had come six miles by train and had walked from the train to the hospital when I saw him. An hour before, whilst at a marriage feast, he put a cartridge into the fire and watched the explosion. Something struck him on the abdomen, he found that he was wounded and bleeding, and came off at once to the hospital. He complained of no pain; his appearance was that of a vigorous man with nothing the matter. In the accident room I found a trifling looking wound above and to the left of the umbilicus, which had bled a little on to his clothing. He requested that this should [illegible] return home and was with [illegible] After proper preparation of [illegible] administration of an anæsthetic the wound was carefully opened up. To our surprise it was found to extend into the abdominal cavity. A rush of blood followed removal of the exploratory finger. The parietal wound was extended upwards and downwards when a quantity of blood, estimated at not less than one and a half pints, was found in the abdominal cavity. The origin of this was a divided artery in the omentum which was pumping freely when caught and tied. Close to this spot, and evidently the cause of the laceration, lay the brass end of a cartridge. There was no other damage done and the patient recovered. The whole of the incidents in this case were a revelation, for nothing but a trifling cut was suspected, and without such a rule as I followed death was inevitable.

[6] See Northumberland and Durham Medical Journal for 1893.

[7] Another argument in favour of more frequent operation has been advanced. It is said (the late Dr. G. R. Slade, THE LANCET, April 22nd, 1905, p. 1059), and statistics lend weight to the statement, that cancer o the gall-bladder is no uncommon occurrence in cases of gall-stone and that cancer follows gall-stone irritation. My own experience, which is limited, of cancer of the gall-bladder does not confirm this; so that I will do no more than mention this view.

Certain abdominal injuries demand immediate operation for their successful treatment and no surgical question is more difficult to answer in an individual case than, Is it necessary to open this abdomen? The guides that I have adopted for my own use are based upon the history of the accident and the physical signs. When the history is one of a sudden severe localised blow, such as that resulting from the kick of a horse, severe visceral injury is so probable that only exceptionally should operation be delayed. When after an abdominal injury there is marked shock careful hourly watch should be kept and the administration of opium avoided. Increasing pallor, increasing thirst, and restlessness with increasing rapidity of pulse suggest internal hæmorrhage and the need for prompt action. Continued severe pain, marked local tenderness, localised muscular rigidity, thirst, vomiting, and a quickening pulse suggest a leak in the gastro-intestinal tract and the need of immediate exploratory operation. It is necessary to emphasise the fact that if operation is postponed till septic peritonitis has developed, and this often does not require many hours, the possibilities are that it will then be useless and may be actually hurtful. Radical operation should never be done when the abdomen is much swollen and tense, for if the intestines are not already paretic the operation makes them so. An enterostomy under local anæsthesia is the largest operation that should be performed in these circumstances and this *may* be useful whether the condition is due to mechanical obstruction or to peritonitis.

TUBERCLE AND CANCER.

There is much that is common in the surgery and pathology of tubercle and cancer. Everyone knows the desirability of removal of the focus of disease in both, with the hope of preventing further infection and generalisation, but not all act upon this knowledge. The most common form of tuberculous disease that calls for surgical interference is that which results from infection of the neck glands. So far as my own knowledge goes it would be practically correct to say that enlargement of a neck gland due to chronic inflammation is always the result of tuberculous infection. I think that every such gland is a source of danger and should be removed. When the operation is limited to the excision of a localised glandular enlargement it is attended with little risk and is followed by a trivial mark and the result is likely to be satisfactory. If, on the other hand, extensive glandular infection is found, neither the immediate nor the remote results of operation are likely to be perfect. The same statement may be made, though even more strongly, for cancer. In both the best results are only [illegible] ed disease. Though [illegible] amount of disease, [illegible] rendered innocuous temporarily or permanently by the surrounding healthy tissues. None will deny the truth of this in the case of tubercle and I think it also holds for cancer. No other explanation can be given of the long immunity after operations, [illegible] partial, done by the older surge[illegible] account for the delay of local [illegible], or even years, after operations for cancer. Not only for tubercle and cancer is this true. The germs of a great many diseases can, and do, lie inert in the tissues ready to become active under favourable conditions but are kept in check so long as the tissues are healthy. This is an important view, because it will necessarily lead to an increased number of so-called palliative operations, and I believe this to be the correct action in certain cases. Contrary to accepted surgical authority, which teaches that unless it appears to be possible to remove the whole disease operations for cancer do more harm than good, my experience is that in selected cases a satisfactory result may follow partial operation.

In the case of tumours of the stomach and bowel it may be justifiable for mechanical reasons alone to excise non-localised malignant growths. In other regions, too, I would suggest that when a large mass of malignant disease can be safely extirpated it should be done, even though glands or other deposits must be left, if it is in a position where sepsis is avoidable. One patient of mine with rapidly growing malignant disease of both ovaries and small secondary deposits in the peritoneum lived for six years, five and a half of which were vigorous, after an operation for removal of both ovaries, before her death from abdominal cancer. (The diagnosis in this case was verified by microscopical examination and by a second operation.)

How much septic infection superadded to cancer or tubercle increases the risks, multiplies the sufferings, and hastens the downward progress of the patient is not sufficiently appreciated. A single example of this in the case of cancer must suffice. I have seen a fair number of cases of cancer of the cervix uteri in virgins, sufficient to be able to make some definite statements concerning them. The disease in them is not attended by the symptoms usually associated with cancer of the cervix—viz., early hæmorrhage and profuse fœtid discharge. Hæmorrhage occurs late; fœtid discharge, if at all, not till after vaginal examination. The first evidence of cancer in unmarried women (and often in widows) is bladder trouble with pains in the course of one or other of the pelvic nerves. Physical examination shows an inoperable fixed mass of malignant disease in the pelvis. Acting upon this knowledge it is possible, and I have done it, to prolong the life and to remove the symptoms, in cases where a radical operation was impracticable, by arresting sepsis. The sharp spoon and regular antiseptic dressings may be successful for months, and in some rare cases for years, in removing the urgent symptoms of this dreadful disease.

A great deal of interest has been excited by the question of cancer and its recent increase and that it is increasing out of proportion to the increase of the population scarcely admits of doubt. So far as my own experience goes, the increase is largely in cases of cancer of the gastro-intestinal tract and especially in cancer of the colon. A very usual history in these cases is as follows. The patient, generally over 40 [illegible] tterly troubled with increasing [illegible] owels to act, more and more [illegible] necessary. Flatulence has been troublesome and flatus has been with difficulty voided per anum. Rumblings in the abdomen have been troublesome and sometimes especially so after taking medicine. They may be sufficiently loud and disturbing to prevent ordinary social or business intercourse. Some loss of flesh is the ordinary rule, but it is not uncommon to see such patients "the picture of health." Physical examination of the abdomen, which is often stout, is likely to reveal nothing. Digital examination per rectum may discover through the wall of the bowel a growth in the lower end of the sigmoid flexure. If it is higher and out of reach of the finger the sigmoidoscope may demonstrate its presence. In women such a growth is heavy and if it occurs in the slack portion of the sigmoid flexure the weight of it makes it fall to the bottom of Douglas's pouch and more than once I have seen it then mistaken for a hard diseased ovary. If examination fails to detect a sigmoid stricture due to the presence of a growth yet if not more than a pint of enema can be retained the fact is in favour of that diagnosis. When in spite of the absence of physical signs the symptoms in a patient over 40 years of age are as I have described them—viz., increasing difficulty in obtaining an evacuation, with painful rumblings, still more if there has been actual obstruction, which may be the first symptom, accompanied by increasing flatulent distension—then exploratory operation should be done without delay. Much as I dislike exploratory operations in general there are good grounds for it here. If a growth be found, as is probable, removal of it may cure the patient or avert by anastomosis the need for a later colotomy, which in many instances is a worse calamity than death itself.

TUBERCLE OF JOINTS.

Tubercle of joints commences, as is well known, in the bone or in the synovial membrane. It is possible now, with the aid of the Roentgen rays, to localise tubercle in the bone before the joint in its proximity is involved. Operation should then be performed with the object of removing the osseous tubercle in time to prevent invasion of the joint. If the synovial membrane is diseased excision of the whole of it precludes the possibility of recovery with a perfect joint. This is so serious a matter that in many cases we must break the rule for tubercle, to excise all infected tissue, and treat tubercle of the joint as an exception. In practical surgery it is necessary to think of tuberculous joints as occurring at three ages—in childhood, in young adult life, and later. In all three it may exist as simple tuberculous infection or it may be complicated by sepsis. It is good teaching to say of tuberculous joint disease in children up to the age of 12 years that recovery without any operation will surely follow complete and prolonged rest of the diseased joint and attention to the general health. In these circumstances even septic tuberculous joints may entirely recover.

In tuberculous joints occurring in young adults before the age of 25 years recovery may be anticipated from the same measures but interference with the functions of the joint is more likely. If recovery is to result in loss of *the functions of the joint I believe excision to be* the best treatment. By excision I do not mean the operations described in text-books as such, most of which should be abolished, but thorough exposure of the joint and the removal of all diseased tissues and of the cartilage covering the ends of the bones, to allow of cure by bony ankylosis, which in advanced cases is the best result to be expected. The test I employ as to whether this is desirable or not is the amount of movement obtainable under an anæsthetic. If there is fair movement excision is not justified, but if movement in every direction is much limited recovery is quicker and more satisfactory after excision. After the age of 15 years and up to that of 35, if a joint is septic as well as tuberculous excision should be the rule. A striking exception to this is met with, however, in septic tuberculous disease of the wrist, a joint which I never excise. Experience has taught me that by prolonged immobilisation of the joint, treatment of the septic sinuses, and attention to the general health, complete recovery with good movement, even in the most unfavourable-looking cases, may be confidently anticipated. After the age of 35 years the prognosis of tuberculous joint disease is very bad and increasingly so in every advancing decade. Operations should, I think, be more frequently done and earlier than they are, for no other means offers a reasonable prospect of recovery. I have now resected joints for tuberculous infection in several patients over 50 years of age with good immediate and remote results. When *tuberculous is complicated by septic infection in elderly* patients amputation should not be delayed.

ABSTRACT OF

An Address

ON

TUBERCULOSIS OF THE KIDNEY.

Delivered before the British Gynæcological Society on June 8th, 1905,

By HOWARD A. KELLY,
PROFESSOR OF GYNÆCOLOGICAL SURGERY IN THE JOHNS HOPKINS UNIVERSITY AT BALTIMORE.

GENTLEMEN,—The nexus between etiology, diagnosis, and treatment is so closely woven that I must touch upon causation, if but briefly, in order to give my little sketch, taken as it were from a surgeon's diary, its due perspective. In the first place, how does the disease reach so recondite an organ? Manifestly there are but three avenues of access: by the blood, by ascending the ureter, and by direct extension from some contiguous organ. Baumgarten of Tübingen (1901) *insisted that the tubercle bacilli* being no *secretionsparasiten* never advance against the current of secretion but always with it. This dictum, generally speaking, is true, although there are good clinical reasons for believing that in man the disease frequently extends from the epididymis to the bladder, where it may involve and cause a stricture of one or both ureteral orifices. This in turn causes a slight hydro-ureter and then follows the invasion of the upper urinary tract. Without any doubt the infection of the kidney is almost always hæmatogenous. It is important to note that the focus by which the blood becomes infected is often found in the thorax. The primary focus, as has been shown by necropsy, is sometimes a cheesy bronchial gland apparently dormant but for this accident. If for any reason the kidney becomes a *locus minoris resistentiæ* it may then become affected by a tuberculosis when it would otherwise have escaped. This is proved (1) by cases of trauma (see especially Newman) followed by tuberculosis; (2) by the occurrence of tuberculosis with calculi (in a case of Heurotius of Chicago the tuberculous disease developed years after the abstraction of the stones); and (3) by the occurrence of a tuberculosis grafted on to a hydronephrosis, in instances too numerous and too entirely in accord with experimental data to be coincidental.

Tuberculosis once started finds in the kidney so favourable a nidus that the disease becomes, with perhaps the rarest exceptions, progressive. Time spent in trying to cure *this disease* by climatic or other methods is lost time, for the affection moves *pari passu* or *per saltum*, but in any case it advances. Delay in active treatment means courting the risk of involvement of other organs. A spontaneous cure is so rare an occurrence that Albarran could successfully challenge the French Surgical Society to produce an indubitable instance. Excluding cases of general and miliary tuberculosis, rarely seen by the surgeon, and excluding those forms of the disease in which it is but a late complication of an advanced and manifest tuberculosis elsewhere, usually pulmonary, we have to deal with a disease which is local and unilateral in its onset and which may remain local and unilateral for months and even for years.

Diagnosis.—The clinical history of this almost malignant bacterial infection of so delicate an organ is characterised by the invariable tendency of the disease to proceed step by step until the kidney has been completely destroyed and *pari passu* with its local progress there is a tendency to become disseminated or to invade other vital organs. The clinical studies of the disease have further demonstrated the fact that the disease when it starts in the urinary tract always attacks one kidney first and then the ureter, then the bladder, and that the involvement of the other kidney is fortunately almost always a late secondary affection. From these considerations it at once becomes evident that if the disease can be correctly diagnosed at an early stage, while it is as yet in the one kidney, a cure may be effected by a complete extirpation. *The great question of importance in every urinary tuberculosis* is as to the accuracy of the diagnosis. In brief, the diagnostician has to consider: (1) Has the patient a tuberculosis of the urinary tract? (2) Is the disease still localised? (3) If the diseased kidney is removed, is the remaining kidney able to do the work?

A satisfactory diagnosis is made when tubercle bacilli are found in the urine at more than one examination and preferably by more than one observer and when these are traced upwards to one kidney and positively excluded from the other. In order to do this the urine as it is collected from the bladder must first be examined; then the separated urines (I use the plural discriminately) must be collected near their sources in the pelves of the kidneys. The diagnosis must include both the character or quality of the infection, as well as the abundance of the bacteria and the question of their constant or intermittent appearance in the urine. In an advanced case with all the signs present the diagnosis is usually quite easy. The patient, often much emaciated and cachectic, has hectic fever, sweats, a rapid pulse, a furred tongue, and anorexia, with a more or less marked low hæmoglobin. There is, as a rule, constant vesical tenesmus, with the passage of urine loaded with pus and sometimes bloody. Palpation in the loin at once reveals, if it is not already manifest to the eye, a more or less manifest tumour on one side. On inspecting the body scars may be found in the neck, in the axilla or in the groin, or there may be a swollen joint or distinct evidences of pulmonary disease. The family history in a large percentage of cases points strongly towards tuberculosis. On making a vaginal examination an enlarged cord-like ureter, sometimes nodular and sometimes so infiltrated and rod-like that it feels as though it would break under firm pressure, is felt through the anterior vaginal wall sweeping round the front of the cervix. Pressure upon this often induces an intense desire to urinate. The opposite fornix is, as a rule, soft and yielding, and here the practised touch readily detects the little normal yielding ureter slipping like a soft wet string between the fingers as it is handled bimanually or is pressed against the pelvic wall. If in a case presenting such earmarks tubercle bacilli are found in a specimen of urine taken from the bladder by a catheter, the diagnosis is assured, and it only remains to determine further the condition of the bladder and of the opposite kidney by a cystoscopic examination, upon which I shall dwell more fully a little later. While the diagnosis of tuberculosis, renal and ureteral, becomes more easy as the disease advances, with the increasing involvement of the bladder comes the difficulty of finding the opposite orifice and analysing the separated urines and so of differentiating the two sides, and when this is not done the diagnosis must be considered incomplete.

The cases most difficult of diagnosis are the early ones in which the bacilli are often sparse or appear in the urine only at considerable intervals. We are obliged here to depend upon repeated examinations of large quantities of urine (24 hours), allowed to stand, decanted, and then the sediment centrifugalised. Sometimes the examiner only finds the bacillus after many hours of search repeated day after day. In this way one who has bad experience and whose suspicions have been aroused by an otherwise inexplicable slight pyuria will sometimes succeed where others have failed. In all obscure cases one of the first steps should be to collect the urinary sediment and to inject it into two guinea-pigs, one into the peritoneal cavities and one under the skin of the groin or axilla. If there is tuberculosis after three weeks the disease will have developed sufficiently to be recognised at the necropsy. The injection of tuberculin is valuable if, in addition to the fever induced, there is marked local reaction in the form of intense pain in the kidney. A practised examiner will in these *early cases often* detect a little thickening or hardening of a ureter on one side as compared with its fellow, which is significant and yet would ordinarily escape notice. It is in these doubtful cases, too, that the *inspection of the* ureteral orifices plays such an important part; a tell-tale blush or puffiness or granular condition will often mark *the diseased side*. The ureteral catheter may then be introduced and the urine from the infected kidney *collected without dilution with that of its fellow. In case* the diagnosis is not clear the physician can well afford to demand the important added element of time and observation, putting off any thought of operation while he keeps his eye on the patient from week *to* week or perhaps from month to month.

Any persistent acid pyuria, as Caspar insists, even of a mild grade, which does not yield an efflorescence of organisms with the ordinary culture media should at once be placed under the category of suspected tuberculosis and the urine centrifugalised *and a test* guinea-pig injected. The following plan is used, adopted from Belgard, cited by Caspar[1]: The urinary sediment which has been centrifugalised and washed with sterile water is injected both intraperitoneally and subcutaneously. The guinea-pigs should at first receive 0·5 cubic centimetre of the old Koch's T.B. If they are tuberculous when this dose is *given it is deadly. One then receives an* injection into the peritoneal cavity of the washed urinary sediment mixed in about 0·2 cubic centimetre of sterile water. The other receives the same quantity subcutaneously. If the urine contains tubercle bacilli in from three to four weeks *following* the subcutaneous injection large palpable glands can be felt *in the fore or* hind feet according to the point inoculated. These glands have already begun to undergo cheesy degeneration and contain tubercle bacilli. The intraperitoneally injected guinea-pigs develop a general miliary tuberculosis with characteristic nodules on the peritoneum, *omentum*, spleen, and in the lungs and kidneys. Any slight persistent cystitis rebellious to treatment should also always be suspected as a possible tuberculosis and in such a case diagnosis must be looked upon as incomplete until the condition of the kidney has been investigated.

The cystoscopic examination.—I prefer to all other methods in these *cases* the direct aeroscopic examination of the bladder. If that viscus is badly affected it is most difficult, as well as [illegible] l to distend [illegible] e ureteral or[illegible] a tight ureter, as well as hazardous to attempt to catheterise the kidney through a medium of contaminated fluid. By my direct method I can see all parts and I do not frequently mistake a painful bladder which screams when the effort is made to distend it for a contracted bladder, which is a rare bugbear in women. I can also cleanse the ureteral orifices before catheterisation and use hard metal as well as flexible [illegible] h a rigid ureter. The [illegible] is a common picture. [illegible] orifice on one side, a pocketed retracted orifice, a deep hole looking like a diverticulum (Fenwick's golf-hole orifice), often tell the tale and *are* finger-posts to the side diseased. If one orifice looks sound while the *other is in the midst* of a diseased area the case promises well. In an advanced case when *most* of the work is being done by one side the orifice *shows* twice the normal activity and it is easy to catch the *urine* as it spurts out in the lumen of the speculum *and to collect* it below and to subject it to a microscopical and bacteriological examination. One may thus avoid catheterising the sound side, although I have yet to see any serious harm done by so doing. The diseased side may resist the entrance of the catheter and when it is once engaged it may bite *it so tightly* that it feels as if held in a vice. *If* the urine does not flow after the catheter reaches the kidney it may be started by injecting a little bland fluid [illegible]

Let me here present in a categorical manner some of the alternatives to be borne in mind in making a diagnosis. 1. Is the organism found the smegma bacillus? How was the urine secured? Was it by voiding or by catherisation? 2. Given the tubercle bacillus in the mixed urines, from which side does it come? Determine by catheterisation, the appearance of the ureteral orifice and the thickened ureter. 3. Is the opposite side entirely free from disease? Bear in mind that a simple pyelitis is not infrequent in the opposite kidney. 4. Bear in mind that the opposite ureter may show marked thickening (perimetritis) and yet the kidney be free from tuberculosis. 5. Note carefully to what extent the bladder is affected as having an important bearing upon the operation and the subsequent treatment. 6. Determine the urea coefficient of the opposite kidney. Is it able to support life? 7. Look carefully for disease elsewhere. Is there a tuberculosis of the genital organs? Is there any pulmonary or glandular tuberculosis? 8. In injecting guinea-pigs remember that tubercle bacilli may pass out of the bladde[illegible] without injury to the kidney. [illegible] kidney found in the loin may [illegible] and therefore the only sound organ. Twice has such a kidney doing all the work of the body been taken out. There is a great risk of making this mistake. With the information afforded by such a complete analysis one is then ready to proceed to the operation with confidence, or at least with full knowledge of the risks incurred.

Treatment.—This consists in the extirpation of the disease in every case which will permit it. The supreme aim of surgery is conservatism but in spite of some notable exceptions it has not done well here. The difficulty is that almost all tuberculous kidneys contain scattered foci [illegible] infection which cannot be seen before the complete removal of the organ from the body. I would only be content to exsect the diseased area in rare cases in which the disease was evidently limited to one pole, as demonstrated by splitting the organ from end to end and down into the pelvis as it lay outside the body before ligation of the vessels and detachment. Now having spoken so strongly [illegible] occur in [illegible] In its pr[illegible] nephrotomy is a precious life-saving measure. I have had several patients apparently in the last stages of emaciation and hectic fever to whom a nephrotomy readily done in from three to five minutes without shock under gas gave immediate relief to the distressing symptoms and enabled them to pick up and to stand a radical operation at a later date. It is important in a nephrotomy to open up all the abscesses in both poles of the kidney.

The radical operations may be conveniently divided into five classes: (1) in the early stages of the disease; (2) in advanced renal disease; (3) with involvement of the ureter; (4) with involvement of both ureter and bladder; and (5) a group of anomalous cases in which the tuberculosis complicates a hydronephrosis or a calculous kidney. Not to enter into unnecessary details before an audience of surgeons let me state that I find the most satisfactory avenue for the exposure of the kidney in the absence of malignant disease to be the posterior lumbar triangle formed by the tendinous aponeuroses of the oblique muscles and lying just below the last rib. The boundaries of the triangle are the oblique muscles, the quadratus *lumborum, and the eleventh or* twelfth ribs. Above the triangle lies the covering of the latissimus dorsi and ventrally lies the retro-peritoneal fat,

other extra- and intra-ureteral conditions was one of the most difficult fields of surgical diagnosis. A differentiation between renal and ureteral colic and lithiasis was practically impossible and yet that division was of vital importance in deciding between expectant and operative treatment. The possibility of determining precisely the size and position of all calculi, or of excluding them, altered the indications for operation in ureteral lithiasis. The detection of a calculus in the kidney is an indication for immediate operation. The indications in ureteral conditions vary with the size and position of the calculi and the accompanying symptoms. A study of the symptomatology of the cases of ureteral lithiasis will help to determine the differential symptoms from renal lithiasis and the indications for operative or expectant treatment in cases of ureteral stone.

The confusion in symptomatology often met in cases of suspected urinary lithiasis renders an accurate differentiation practically impossible. There may even be such a lack of symptoms that a diagnosis of calculus is not justified and yet a calculus will be found to be present by the Roentgen method. Any differentiation between renal and ureteral lithiasis by symptomatology cannot be applied to every case nor can it be considered possible except in typical cases. In certain cases, however, a symptom or group of symptoms will render probable the presence of a ureteral rather than a renal stone. The study of the symptomatology will give a clearer idea of those symptoms that point to a position of ureteral stone and demand the employment of the Roentgen method to establish the presence of, or exclude all, calculi. The earlier the cases come for diagnosis the more efficient and valuable will be the treatment and this end will be furthered by a better understanding of the suspicious symptoms. This end can be best attained by discussing the atypical symptomatology and attention can be confined to those particularly indicative symptoms that materially assist in differentiating between renal and ureteral involvement, and also those which when taken in conjunction with the Roentgen diagnosis of a ureteral calculus indicate the probability of its passage, and that expectant treatment should be instituted rather than immediate operation.

The anatomical conditions and physical forces that come in play when a calculus becomes impacted in the ureter and act to propel it downward are responsible for much of the variations in symptomatology. The impaction of a calculus causes a stoppage of the urinary flow and thus a gradual distension of the pelvis of the kidney and ureter. The pelvis and ureter are capable of contracting upon their fluid contents and thus a hydrostatic pressure is brought to bear upon the calculus. The normal peristaltic wave has probably very little to do with the expulsion of a calculus. The *vis a tergo* is purely hydrostatic, resulting from the spasmodic contraction of the viscus. This force has a twofold action: it tends to distend the ureter at the seat of impaction of the calculus and to push the calculus along the distended ureter. The result in the progress of the calculus is largely dependent upon the size and character of the stone, a factor that also influences materially the symptomatology. The urine may distend the ureter and escape around the calculus without pushing it before it or it may gradually work the calculus down the ureter. The most frequent seats of impaction have been the uretero-iliac junction, the juxta-vesical portion of the ureter, and the narrow portion an inch or more below the lower pole of the kidney. The frequency of impaction has been in the order named, while all multiple ureteral calculi have been found in the juxta-vesical portion of the ureter.

The impaction of calculi and much of the variation in symptoms are due to their shape, size, composition, and the presence or absence of infection. So long as infection is absent and the calculus does not produce obstructive symptoms it may remain for a long time without producing suggestive symptoms. In the kidney the larger the calculus the less liable is it to produce severe symptoms. In the ureter very small smooth calculi may pass almost unnoted and yet in one case (No. 226) a smooth oval calculus composed of earthy phosphates and uric acid and weighing only 0·096 gramme had produced two previous attacks and a final attack that lasted 11 days before the calculus was passed. The rougher the calculi the longer and more painful will be the attacks and the more chance there will be of finding blood in the urine.

The larger calculi which enter the ureter are liable to produce repeated attacks of ureteral colic with an almost constant dull ache in the lumbar region, due to the intermittent hydronephrosis. On the other hand, the simplest and gravest conditions may be present where there are aseptic calculi of no matter what form. The very absence of symptoms, which is the condition generally accompanying them, is the gravest element of danger. Undetected or unsuspected calculi are a grave menace—a menace which is removed when their exact position and size are known. The importance of this method, which accurately determines their presence or absence, is self-evident.

In studying the characteristic symptoms which differentiate ureteral from renal lithiasis it must be borne in mind that often any accurate differentiation is impossible and that in many cases symptoms only suggest the possibility of a calculus with no way of determining its presence, even much less of accurately locating it. There are, however, certain differences in the nature and character of the symptoms present in ureteral and renal colic that should suggest the presence of the calculus in one or the other portion of the urinary tract. The pain experienced may in general seem identical and yet when the exact location of the calculus has been determined by the Roentgen method marked characteristics can often be noted. A dull ache in the lumbar region is common to both; it may be constant as the result of a large quiescent renal calculus, either sterile or in a pyonephrotic kidney. In ureteral lithiasis the dull ache is due to the obstructed flow of urine and the gradual distension of the kidney and ureter. The renal condition seldom presents colic attacks unless clots of blood from a loosening of the calculus or masses of pus produce obstructive symptoms. The pain even then is not so lancinating in character during the sharp attack. The renal stone that produces a constant ache seldom produces obstructive symptoms of itself. The ureteral calculus causes an increasing ache as the obstruction becomes complete, which is due to the increasing hydronephrosis and forms a prodromal stage to the acute attack. The attack is sharper. The fulminating point of the colic pain is low down in the line of the ureter. The pain is more lancinating and is generally accompanied by nausea and vomiting. The lumbar ache persists after the attack, unless the calculus has been expelled, and generally subsides gradually. This prodromal stage and gradual subsidence of the lumbar pain differentiate ureteral colic from renal colic, due to the temporary impaction of a small or medium sized calculus in the infundibulum of the ureter, and the sharp attack of renal colic it produces and also from the dull constant ache without exacerbations of the large quiescent renal calculus.

The fulmination point of the colic attacks and the direction of radiation are also often very characteristic. The acute pain of renal colic may go in all directions, around the body and to the stomach, as well as down the line of the ureter to the testicle and scrotum. The classical descriptions of renal colic grouped together all the symptoms, confusing and confounding them. The accurate localisation of the calculi during the attack has rendered the differentiation possible. The pain of ureteral colic radiates in the paroxysms up to the kidney as well as down through the ramifications of the genito-crural nerve. The pain is located in the testicle, the scrotum, the labium major, along the urethra, in the line of the groin, the inner side of the thigh, the knee, or even the foot; generally in more than one of these points, sometimes in nearly all. It also has an upward direction and in addition to the dull lumbar ache there are acute pains during the colic attack which ascend the ureter and involve the kidney or pass to the stomach causing nausea and vomiting. A reflex symptom in addition to the tendency to nausea and vomiting, often present in ureteral stone above the iliac artery, is due to irritation of the psoas muscle. Its relaxation is often sought as a method of relief, flexing the thigh upon the pelvis and *this in turn upon the spine.* The relief afforded can be readily explained by the straightening produced in the ureter at its iliac crossing, and is one of Nature's methods of facilitating the passage of the calculus.

The symptoms change for calculus below the iliac artery and will be considered further on. In ureteral stone at or above this point palpation often affords valuable confirmatory evidence. The most common point at which a ureteral calculus can be palpated is at the uretero-iliac junction, where the ureter crosses the common iliac artery and dips down into the pelvis. This is a point of narrowing and bending of the ureter which often causes impaction. In most patients this point can be readily detected and in all where the bifurcation of the iliacs from the abdominal aorta can be palpated. After determining this point the finger is carried to the right or left and downward along the line of the common iliac artery for an inch or one and a half inches. The pulsation in the common iliac can generally be felt. Along this line an acutely tender point will be encountered, "like touching a sore tooth," as the patient expresses it, and often the hardness of the calculus can be perceived. Sometimes it is possible to follow up the distended and tender ureter from this point. The tenderness in these cases can, however, be readily confused with that of a ureteritis of tuberculous origin or one which accompanies a condition of surgical kidney. Palpation may also detect the hydro-ureter and hydronephrosis. The marked and fluctuating intermittent hydronephrosis resulting from calculous obstruction of the ureter has frequently been mistaken for a floating or moveable kidney, the kidney in its distended condition being mistaken for a displaced organ.

Pain and tenderness are, however, very misleading symptoms in the differential diagnosis of extra-ureteral conditions from ureteral lithiasis. Pain localised at the uretero-iliac junction and the tenderness along the ureter have been mistaken for appendicitic and ovarian disease. In two of the cases the patient has been previously operated upon for appendicitis while one had also had the kidney stitched in place. In both the ureteral calculi were subsequently recovered. My friend, Dr. Boggs of Pittsburgh, has had a similar experience, finding ureteral calculi in two cases which had previously been operated upon for appendicitis without relief from their symptoms. The possibility of this confusion in symptomatology was first mentioned by me in 1902 in a paper before the American Medical Association.

After the calculus passes the iliac artery the next point of possible impaction is at the bend near the iliac spine at the commencement of the juxta-vesical portion of the ureter. Calculi, however, more generally become impacted at the vesical end of the ureter where it enters the wall of the bladder. The symptomatology of calculus in this portion of the ureter differs decidedly from that where the calculus is higher up. True, there are lumbar ache, a sense of fulness, and possibly a palpable renal tumour but the majority of the symptoms are referred to the bladder and simulate vesical stone. There is pain referred to the glans penis or the meatus in the female and to the urethra in both. The pain may follow urination or may be entirely distinct from it and so severe in the urethra as to amount to veritable strangury. There is generally less involvement of other branches of the genito-crural nerve. Though pain is often complained of in the groin, and pain referred to the other side of the abdomen, it was felt in only one case in which the calculus was situated in the juxta-vesical portion of the ureter, while the pain was chiefly felt on the opposite side. Small calculi impacted in this portion of the ureter have given rise to the most severe symptoms. In one case there were complete obstruction and a pyo-uretero-nephrosis with high fever that demanded immediate operation. The obstruction was caused by three small calculi no larger than grape seeds. In another the bladder had been explored by cystotomy for encysted stone. In two or three other female patients persistent local treatment for the cystitis had been carried on for some time without any alleviation of the symptoms. A calculus in the juxta-vesical portion of the ureter can often be palpated either per vaginam or through the rectum; sometimes, however, minute calculi cannot be detected in this manner, especially if they lie in the para-sacral or the first part of the juxta-vesical ureter.

The differential diagnosis of renal from ureteral lithiasis is only valuable in formulating the indications for treatment. The study of the symptomatology of those conditions which simulate ureteral or renal stone that are intra-ureteral or renal show the importance of the Roentgen method of diagnosis, while an attempt to differentiate intra- from extra-ureteral conditions shows how impossible in many cases is any accuracy in diagnosis. In fact, exploratory operation as a method of diagnosis is often necessary, where an accurate diagnosis cannot be reached by other methods after calculus has been excluded and the symptoms indicate the presence of a grave condition that threatens the functional efficiency of the kidney. The greatest value of the Roentgen method of diagnosis is found in its combination with other known methods and yet its importance as a diagnostic method is very evident when the impossibility of differentiating urinary lithiasis from other conditions is realised. The elimination of calculous conditions by this method is essential to the rational treatment of all cases of ureteral and renal disease. This may be said of even the so-called purely medical diseases of the kidney. Ureteral and renal calculi have frequently produced an irritation of the kidney that has been expressed in an albuminuria without other symptoms which has been mistaken for chronic interstitial nephritis or for Bright's disease.

In difficult cases of suspected ureteral lithiasis urinalyses are frequently of little value and are generally negative. The presence of red blood cells immediately after a severe attack of colic is of the utmost importance and yet they may be entirely wanting. A small amount of albumin is almost constantly present but is of little value in differential diagnosis. The crystalline deposits in the urine are valuable, because they aid in determining the quality of Roentgen discharge that may be safely employed in the search for calculi; where there are no crystals present the preponderant salt may be determined by refrigerating the urine. The crystals thus precipitated can be recognised under the microscope. Their value is, however, only relative.

The determination of the amount of urea excreted forms the safest guide in expectant treatment, as it determines the functional capacity of the kidney and shows whether it is sustaining injury from the presence of the calculus. In the difficult cases of diagnosis urinalysis is often of very little value as the urine may be perfectly normal and yet very grave conditions may be present. It is not, therefore, a method upon which much dependence can be placed in cases where a negative finding is made. An estimate of the value of any method of diagnosis in suspected calculous conditions can only be made by comparing it with the results obtained by other methods, both in detecting and excluding calculi from the urinary tract.

Probably the most striking proof of the accuracy of the Roentgen method is that it has shown that ureteral colic and calculi are more frequent than renal colic and that it has led to a differentiation between the symptoms of these two conditions. The increased frequency of ureteral stones is not due to their more frequent occurrence but to their recognition by a more accurate method of diagnosis. A fact recently made known to me by several operators, and one which is true in my series of cases, is that as the technique becomes more perfect the proportion of ureteral calculi detected increases. In considering the accuracy of this method the personal equation of the individual operator must always be taken into account. Although this diagnosis depends for its accuracy upon its mechanical method of obtaining results, those results will not be accurate unless it is employed properly. The skill and experience of the individual operator with this method must therefore be taken into consideration in every case and his percentage of error estimated. Not only must the technique be capable of producing a negative upon which both the positive and negative or exclusion diagnosis can be based, but the operator must also be able to translate the diagnosis from the negative which he recognises to be satisfactory. This is often the most difficult part that depends for its value upon the clinical experience of the operator. The introduction of this personal element introduces the only source of error in a method which otherwise would be mechanically accurate. Infallibility has never been claimed for this method, but clinical experience shows that it possesses greater accuracy than any other method when correctly employed.

In the series of cases upon which these conclusions are based there are many cases which prove its greater accuracy. Competent surgeons have failed to find encysted calculi, calculi imbedded in the substance of the kidney and one or more of multiple calculi have been left behind, while calculi in both kidneys or in kidney and ureter have led to incomplete and later second operations. In four cases calculi left behind resulted in urinary fistulæ that healed after the calculus was removed.

The possibility of these errors has been admitted by the best operators and the most eminent writers. Mr. Henry Morris said: "Even when the kidney is exposed to the eye and has been palpated all over, and exploratory punctures have been made systematically in every direction into its substance, a calculus may yet escape detection." It can be added with equal truth, as the experience of other surgeons, that the kidney may be split open and yet a calculus will escape the exploring finger. This has been proved by my own experience in this series of cases where calculi in both the kidney and ureter have been found after operations by skilful surgeons and in one case where a calculus detected by the Roentgen method was not found by the first operator but was subsequently removed by another. Literature has also many examples that show how common incomplete operation has been and how frequently small ureteral calculi have been passed after an unsuccessful nephro-lithotomy.

The accuracy which has been demonstrated for this method by clinical experience has led me to hold that the negative diagnosis where proper technique and skill have been employed and a satisfactory plate has been obtained is of such accuracy that surgical interference with the purpose of detecting calculi is unnecessary and not justified. That is, in an exploratory operation upon the kidney, unless some macroscopic pathologic lesion is found, an incision into the kidney to seach for calculi is not justified. This cannot be held to be true of the fluoroscopic examination of the kidney during an operation or at any time. The delicacy in detail, essential in a radiographic negative before an exclusion diagnosis can be made, shows how impossible are the claims of accuracy by the fluoroscopic method.

This claim of accuracy for the negative or exclusion diagnosis is borne out by the statistics of the cases examined by myself. There have been but four cases in which calculi have been found on operation or passed in the series of 330 cases examined since I claimed equal accuracy for the negative and positive diagnosis, and the negative diagnosis has been confirmed by operation 47 times. There have been six other cases in which the surgeon failed to find a small calculus detected by the Roentgen ray or in which only a mass of cretaceous substance was found in the pelvis of the kidney. It is probable that half the errors were due to defective operating, a delay after the examination sufficient for the calculus to pass, or its escape during the operation.

The value of an accurate negative diagnosis is very great; it not only renders unnecessary exploratory operation for stone, but often all operations can be avoided and the patient treated by purely medical methods. There are many cases of oxaluria and phosphaturia in which the symptoms so strongly suggest calculous conditions as to render operation necessary unless an exclusion diagnosis can be made. On the other hand, the gravest conditions of calculous anuria, with scarcely no symptoms, are so serious that their treatment by medical measures would surely result in death. The differentiation of extra-ureteral conditions from ureteral lithiasis is often very difficult and yet the exclusion of calculi renders their recognition and treatment possible. But including all these cases as due solely to errors in Roentgen diagnosis the total amount of error in both the positive and negative diagnosis is less than 3 per cent. of the 330 cases examined. This is a percentage of error that compares very favourably with any other method, or all other methods of diagnosis, including exploratory nephrotomy.

In comparing the dangers of other methods this method is shown to be far preferable. The only danger lies in a possible chance of x ray burn which cannot be absolutely excluded but is of rare occurrence. The method is much less dangerous and more accurate than segregation of the urine, ureteral catheterisation, cystoscopic examination, or even sounding of the bladder. While all these methods are valuable and should be used in conjunction with the Roentgen method, there is an element of danger due to infection that makes that routine employment in aseptic cases a matter of grave doubt, while where infection of the bladder is present, ureteral catheterisation, either through the cystoscope or retrograde catheterisation during nephrolithotomies, is unjustifiable, as infection will probably be carried to the kidney. The danger is equally great no matter which way the catheter is passed, as its withdrawal from the bladder to the kidney in retrograde catheterisation can cause infection.

Upon what, then, shall operative intervention be based in calculous conditions and how shall a differentiation be made between cases in which operation is demanded and those in which expectant treatment is indicated? In renal lithiasis the detection of a calculus by the Roentgen method is of itself an indication for immediate operation. This is true even where ureteral calculi are also present. The indications for treatment in cases of ureteral lithiasis have been greatly modified by the greater accuracy and exact knowledge afforded by the Roentgen method of diagnosis. In a paper before the surgical section of the American Medical Association in June, 1901, I pointed out the effect which this method of diagnosis had had upon the indications for operation. I showed that it furn
rational and safe course of
established and that with th
safe to leave to nature that w [illegible]
be accomplished without danger to the patient. Such a course of treatment must necessarily be carried out under strict supervision. The result of the employment of that method has been the passage of calculi in 26 cases without operation—a result which attests the value of this method of treatment.

The tolerance by the ureter of a calculus in it, when there is no infection present, has been previously demonstrated by many cases reported in literature in which patients have passed long series of calculi. There are two such cases in those recorded by myself. The detection of a calculus by the Roentgen method does not therefore constitute an indication for its immediate removal, it rather establishes an indication for non-operative treatment if its size indicates the possibility of its passing and there are no complications that point to immediate removal.

The conditions that indicate immediate operation in the presence of a ureteral calculus are the detection of a renal calculus in one or other kidney, the large size of the calculus making it improbable that it should pass, the presence of infection, pyrexia, &c., showing that the vitality of the kidney is endangered and the absence of urinary flow from the affected ureter, as suggested by a sudden decrease in the amount of urine passed or in the excreted urea and demonstrated by the absence of flow as observed by the cystoscope. Where the calculus is small and even where there are multiple calculi if there is a history of repeated attacks of colic marking the progress of the calculus down the ureter there is great probability that the calculus can be passed by natural channels.

The mortality from ureter-lithotomy is high, especially for calculi situated in the para-sacral or juxta-vesicle portions of the ureter, unless they can be reached through the bladder or the vagina. With a series of 26 cases of ureteral calculi that have been passed under the expectant plan of treatment it is reasonable to advise this course of treatment when safeguarded by the exact knowledge of the size, position, and number of the calculi, making immediate and accurate intervention possible if urgent symptoms demand it.

While the presence of an undetected calculus may be a grave danger and a menace to the integrity of the kidney, so soon as its exact size and location are known that menace ceases unless there are symptoms present that indicate a progressive impairment to the function of the kidney. Comparatively few of the migrating calculi give rise to anuria or the greater proportion of patients suffering from ureteral stone would die. The relative infrequency of symptoms that demand operation for ureteral stone is indicated by the fact that in only 15 cases was operation employed, and even then possibly the calculi would have passed, while 26 patients passed the calculi without operation. Many cases operated upon were complicated by multiple or renal calculi that demanded immediate operation.

The symptoms that suggest the employment of expectant treatment are a constant dull ache in the lumbar region with a history of repeated acute attacks of ureteral colic that have been referred to the location of the calculus. There may or may not be blood in the urine as an evidence of the progression of the calculus, but pus and the indications of ureteral and renal infection should be absent. When these symptoms, and possibly a palpable hydronephrosis, are found in conjunction with a Roentgen diagnosis that shows a calculus of moderate size in the ureter; they may be considered as sufficient indications of a vitality and force in the kidney that will finally expel the calculus. Each attack of ureteral colic is an indication of Nature's efforts in expelling the calculus and generally means a distinct progression. The attacks should be welcomed as indicating a near approach to expulsion. The patient should not be put to bed or advised to keep particularly quiet unless there are dangerous symptoms that demand immediate operation. Large quantities of any naturally alkaline mineral water should be taken. Their efficiency is probably due to their volume and diuretic action rather than to any solvent tendency, though they tend to prevent concentration of the urine and possible increase in the size of the calculus. Glycerine in teaspoonful doses has been recommended and has been employed in several of the cases that have passed calculi. Its direct influence upon the passage of the stone cannot be, however, determined. Urotropine has had remarkable efficacy in rendering or keeping the urine sterile. No direct benefit has been seen from the use of piperazine, although it may have decreased the formation of uric acid; the evidence has been purely negative. In phosphaturia and cases where

an aggravated character would persist for days. Over the upper part of the right scapula a diffuse swelling was noticed; the measurement under the axilla and over [illegible]

Being anxious not to overlook sarcoma and tuberculous disease I sent her into hospital to a surgical ward where she was kept under observation for a few days and examined with the [illegible] was observ[illegible] section of our branch of the [illegible] a possible case of myositis. When examined the reason for suspecting sarcoma was readily appreciated. Little definite opinion as to the case was expressed except that it was probably not myositis but neuritis following injury of the brachial plexus. By this time the patient was already under treatment with sali[illegible] night) and a purin-free diet [illegible] for the meat and tea system [illegible] the exquisite tenderness and pain it was not deemed advisable to adopt any local treatment. For six weeks no improvement was noticed; then the excessive sensory disturbances began to diminish. The salicylate of sodium was taken every night for six months and then discontinued, as the pain was much less and the whole condition was better. By this time anæmia, which had been a prominent symptom at first, had almost disappeared and that without any iron being given. At this period there was found to be a marked difference in pulse tension on assuming the erect posture, due to poor tone of the abdominal muscles; a course of exercises for these muscles was therefore instituted. After nine months the patient, who had led a useless life for nearly three years, began to do housework and also a little needlework; three months later she could sew without much difficulty and a few weeks afterwards was able to resume her work as a dressmaker. She adheres to the diet, as she finds that it suits her so well. She is now in a good state of health, has married, and has a baby.

It is unnecessary to bring forward more cases in support of the view that this system of diet is a potent remedy in certain forms of chronic illness; it is also a useful adjuvant in disorders of a less chronic nature and especially in those that are generally designated as gouty, rheumatic, or neurotic. As an instance of the latter may be mentioned the following.

CASE 4.—The patient was a young married woman who had been confined three months previously of her first child. While wheeling her perambulator she suddenly felt faint and overcome and lay down at the side of the road, but did not think that she became unconscious. After a short time she recovered somewhat and was able to make her way home in a dazed condition. Similar attacks recurred and on one occasion when I was in the house. While talking she complained of feeling faint and lay down on the sofa. For a few minutes she was semi-conscious; the face was cyanosed and the pulse was strong. There was no cardiac lesion. This was no attack of syncope. The older generation of practitioners would have called it hysteria. The patient was, however, known to have a large appetite, especially for meat. A diagnosis of vaso-motor disturbance due to an excess of purins therefore seemed reasonable. Under treatment on these lines she rapidly improved and ceased to have the attacks.

The usual objections to the diet are, that it is difficult to digest, that it is impracticable, and that it is insufficient for ordinary life and health. The first is due to the misleading idea that a purin-free diet is necessarily a vegetarian one. The second is at once answered by the fact that no diet can be simpler or less expensive than one selected from milk, cheese, butter, white bread, cereal foods, nuts, and fruit, without any cooking being required. The remaining one carries little weight because it is usually made on *a priori* grounds by those who have had no proper experience of this system as well as the ordinary one. Those who have given both a fair trial in the case of themselves and patients—and there are now a considerable number of such men—are in a position to state that the new system is adequate for nutrition and energy; indeed, they find that the general standard of health is vastly improved and the capacity for work greater. Many of the Japanese subsist on a purin-free diet, yet are not deficient in enterprise or concentration in any kind of work. This is not to be explained away by differences of race and climate, for extraordinary feats of endurance have been accomplished both in this country and in America by athletes trained on a simple diet. Several professional men, taking no other food, have worked for years with vigour and success.

"In order, however, that no one may object that while this is all very well for the athlete, who reserves all his energies for one effort, and for the sedentary professional man, yet it will not do for laborious work, I may refer to the case of a puddler who states that he has been a simple feeder for 11 years and that he can undertake to do more than a meat-eater; at his works it is a recognised fact that he and his mates who have adopted this system of feeding accomplish the most. The recent experiments of Chittenden and others have proved that our former notions of the necessities for nutrition are extravagant. For a generation ideas in dietetics have been dominated by the statements of one or two investigators whose conclusions have been unhesitatingly accepted in spite of obvious fallacies. In the first place, diet experiments conducted for a few days or even weeks must be valueless; such investigations require months at least. Most people are upset by a change in diet and a revolution so great as that from the ordinary to a purin-free one must be extended over a period of not less than 18 months. Many people eat too quickly and would find their nutrition improved by more efficient mastication; this should be attended to in all experimental work. The exact state of health at the beginning and end of the investigation must be noted, and records of the pulse tension, of the capillary circulation, and of the hæmoglobin percentage made. Certainly a more accurate estimate must be formed than the popular one which accepts headaches, indigestion, rheumatism, constipation, colds, and influenza as the inevitables of life rather than as evidence of faulty habits. I know several men who after changing gradually to a purin-free diet have found that during a period of years they have remained free from such disturbances, although previously they had not. Their experience has been that they can do more work and that whereas they could only bicycle perhaps 20 or 30 miles without fatigue they can now ride from 50 to 100 without effort.

It has already been hinted, and must be distinctly understood, that though a vegetarian diet may be made purin-free it is not the most desirable, nutrition and vigour being maintained with difficulty. Meat should be replaced by something of greater caloric value, such as cheese; while if purin-containing substances are excluded there is no necessity for vegetables. The staple food should be selected from milk, cheese, nuts, and cereals, with fruit as a sauce. Great variety is possible. In Haig's small work on "Diet and Food" will be found a complete account.

Till recently the results of diet have been largely matters of theory; with the introduction, however, of Walker Hall's purinometer we have an exact test. It is true that many examinations for uric acid and its congeners were previously made, but most of the methods were untrustworthy and too complicated for ordinary clinical work. The purinometer, however, which is fully described in Walker Hall's book, "The Purin Bodies of Food-Stuffs," is a useful clinical instrument suitable for any medical man. It will not satisfy the observer who expects to have merely to pour a reagent into a tube and read off the result; yet it is quite simple and takes up little time, only some 10 or 12 minutes when the test is started and 10 minutes more when the results are worked out. The fallacies are few. As an instance of its value one or two cases may be cited.

CASE 5.—The patient, a woman subject to rheumatism, consulted me on account of extreme depression which made life unbearable. With this instrument the purin nitrogen in 24 hours was found to be 0·35 gramme, an amount ample to account for the symptoms. A change in diet was advised, the exclusion of tea, coffee, soup, and beef tea being recommended as the first stage. A week later the purin nitrogen was 0·23 gramme and the patient felt better. After a few weeks a plain breakfast was substituted for the former one, and a little later meat and fish were also eliminated from a second meal. On this *régime* the register two months after [illegible] The [illegible], and [illegible]

CASE 6.—The patient, a young man employed in a bank,

making valid distinctions between them The cells described [illegible] lymphocytes in construction [illegible] extremely large They are [illegible] indifferent lymphoid cells and the large lymphocytes in the blood in acute lymphæmia Death occurred at 3 A M on March 20th

Necropsy —A post mortem examination was made nine hours after death The body was markedly jaundiced The thoracic viscera appeared to be normal The thymus was large but not abnormally so and showed no gross alterations The liver was somewhat enlarged, firm, and bile stained The spleen was greatly enlarged and unusually firm on section, deep red in colour, and weighed 370 grammes (13 ounces) The lymph glands all over the body were distinctly enlarged and their colour was deep red, almost as deep as that of the spleen Peyer's patches and the solitary follicles of the intestine were also red and hypertrophied The marrow of the femur and ribs was red Pieces of the liver, spleen, lymph glands, bone marrow, and thymus were taken for microscopic examination Some of the material was fixed in 75 per cent alcohol and after going through 90 per cent and absolute alcohol was imbedded in paraffin Other pieces were fixed in a mixture of potassium bichromate (2 5 per cent) and formalin (15 per cent) for 24 hours and after remaining in 3 per cent potassium bichromate, which was changed daily, for a week were washed out, dehydrated, and imbedded in paraffin The alcohol material was first examined but proved unsatisfactory owing to the coarse fixation of the cytoplasm The erythrocytes also appeared to have lost their hæmoglobin The bichromate formalin material, on the other hand, was very well fixed, there being an almost complete absence of shrinkage and perfect cytoplasmic, as well as good nuclear, fixation Various staining methods were employed but the most useful was Jenner's eosinate of methylene blue in absolute methyl alcohol used as follows Sections mounted on albuminised slides, after having the paraffin removed, are washed with absolute alcohol and put into well corked specimen tubes of Jenner's solution for an hour to overnight The slide is then taken out of the tube and rapidly wiped clean A few drops of the solution are then poured over the section and an equal quantity of distilled water is added and mixed rapidly The slide is then kept moving from side to side and the section from pale blue becomes dark blue if it has many basophil constituents, while the oxyphil elements become pink It is found that when a scum begins to form on the surface the section is sufficiently stained It is then washed in water and examined under the microscope (preferably with a water immersion objective such as Zeiss D*) If there is then too much blue either in the red cells or so as to obscure detail, it is rinsed in a weak watery solution of acetic acid not stronger than 1 in 2000, till a little blue comes away It is then dehydrated quickly in absolute alcohol, cleared in pure benzene (crystallisable benzene free from thiophene[1]), and mounted in Grubler's pure neutral balsam dissolved in pure benzene The method in principle is that of L [illegible]

The bone marrow — [illegible] mate this was decalci[illegible] before imbedding) Blood cell formation is going on actively and mitoses are frequent Megaloblasts are present The appearances agree completely with the view originally, we believe, enunciated by Saxer and since upheld by Wolff Pappenheim, and others The cell from which all the others can be traced is a cell whose construction and staining reactions are those of a lymphocyte which only differs from the ordinary lymphocyte of the blood and tissues in its greater size and the fainter staining of its nucleus This is the indifferent lymphoid cell of Wolff and the basophil myelocyte of Dominici

From this develop the neutrophil and eosinophil myelocytes The mechanism of their development is as follows In the cytoplasm, generally in one spot near the nucleus, the specific granulations appear At the same time, in this spot the cytoplasm begins to lose its basophily and the granules lie in an unstained space More granules appear until eventually the cell body is full of granules and the cytoplasm has completely lost its basophily Simultaneously with this granule formation the nucleus becomes smaller and more deeply staining The myelocytes thus formed develop into the adult polymorphonuclear cell Mast cells were almost absent in this marrow

Between the indifferent lymphoid cells and cells like ordinary small lymphocytes there is every transition and we find it quite impossible to say where this small lymphocytic cell ends and the polychromatophilic normoblast begins As mentioned above, there was the same difficulty of distin[illegible] latter classes of [illegible] e from a cell of [illegible] hate between the [illegible] mphocyte The nucleus becomes deep staining before the cytoplasm begins to alter This transition one of us has observed recently in a case of lymphæmia

The spleen —There is no fibrosis or any degenerative change to be seen The organ is densely packed with erythrocytes and various kinds of leucocytes The Malpighian bodies appear to be normal at their centre, but at their periphery indifferent lymphoid cells, neutrophil and, in greater abundance, eosinophil myelocytes are seen The presence of these cells and transitions from the former to the two latter is most noticeable at the edge of the Malpighian bodies and along the finest trabeculæ leading from them They are present, however, throughout the organ, but are scarcer in the other parts, or else their presence is masked by the vast numbers of red cells and normoblasts which form the most striking feature of the section The endothelial elements of the spleen pulp are not prominent nor have we found evidence of blood cell destruction

The lymph glands —These bear no resemblance to normal lymph glands but have undergone complete transformation into red bone marrow, so much so that all stages of blood-cell formation can be seen here as well as in that tissue Giant cells, with large convoluted and deep staining nucleus and homogeneous cytoplasm with little affinity for dyes, corresponding to the megakaryocytes of Dominici[3] are frequent They appear to be phagocytic, for occasional leucocytes and red cells can be seen englobed by them There [illegible] the sin[illegible] brown [illegible] These latter also contain many myelocytes and adult leucocytes and normoblasts

The thymus —This organ does not show the myeloid transformation seen in the spleen and lymph glands but occasional myelocytes can be seen most of which are eosinophil The most frequent situation is in the connective tissue between the alveoli of lymphadenoid tissue Eosinophil cells, however, seem frequently to be found in the thymus Normoblasts are seen occasionally in the vessels but that is of little importance since the blood contained about 7500 of them to the cubic millimetre

The liver —The lobular arrangement is not at all clear There does not appear to be any fibrosis or inflammatory change The cytoplasm of the liver cells is scantier and more reticular than in the adult somewhat resembling that of the fœtal liver Some of the cells are degenerate and have homogeneous, diffusely staining nuclei Bile is seen frequently in the intercellular bile capillaries and occasionally in what appear to be intracellular bile canaliculi In the connective tissue spaces of the portal tract and the capillaries throughout the liver there can be seen indifferent lymphoid cells with erythrocytes and myelocytes, both neutrophil and eosinophil, developing from them as in the bone marrow, spleen and lymph glands Mast cells are scanty One megakaryocyte was seen in the examination of many sections In short, it is a fœtal—i e , a hæmopoietic—liver, to which are superadded some parenchymatous degeneration and the injection of the bile capillaries met with in obstructive jaundice

We have then, in this case complete myeloid transformation of the lymph glands and spleen , in fact, the former are as myeloid as the marrow itself The liver also participates in blood cell formation, behaving as a fœtal liver

Dominici,[4] working on animals in experimental infections and anæmia produced by frequent abstractions of blood, has found that in these conditions the spleen takes on the functions of red bone marrow Hirschfeld[5] examining the spleen and lymph glands of the human subject post mortem, has found that in severe infections the spleen assists the bone marrow in the production of neutrophil myelocytes and polymorphonuclears and that, to a lesser extent, the lymph glands participate in this function. He frequently found eosinophilic myelocytes in them, but very rarely normoblasts. When we turn to anæmias we find less written about the spleen and lymph glands. Wolff[6] [illegible] case of anæmia due to chronic [illegible] bone marrow was defective in the pr[illegible] neutrophils, [illegible] that the spleen, although not enlarged, was producing them freely. Hirschfeld[7] quotes Rindfleisch as having, in [illegible]31, found normoblasts in the lymph glands of a child with [illegible]æmia and marked rickets. Fowler[8] and Melland,[9] dis[illegible]ing splenic anæmia of infants, have very little to say [illegible] the histology of the condition, with the exception [illegible] Fowler found eosinophilia of the spleen in two cases. [illegible]utchison[10] in his Goulstonian lectures for 1904 reviewed [illegible]eports of the histological findings recorded by various [illegible]vers. From these reports it appears that we can as yet [illegible]ate no definite morbid anatomy and histology for the [illegible]ion. He quotes, however, Luzet, Mya and Trambusti, [illegible]nt as having, in their cases, found the liver to be fœtal [illegible] our case. Fowler[11] mentions jaundice as occurring [illegible] cases, twice transient and once associated with [illegible] epatitis. We can offer no satisfactory explanation [illegible] this case. The results of the blood examination [illegible] abnormal for infantile splenic anæmia, and accord [illegible] those given by Fowler, Melland, and Hutchison, [illegible] at the count of erythroblasts was very high, 7500 [illegible]ts and 400 megaloblasts per cubic millimetre. [illegible]entions one case with 9353 erythroblasts.

[illegible] production of the anæmia our investigations give [illegible] The phagocytosis of erythrocytes in the lymph [illegible] not a very marked feature, while we have seen [illegible] in the spleen, as opposed to the findings of [illegible] Herzog[12] in splenic anæmia of adults. If [illegible] been no blood examination the histology of [illegible]rming organs would have suggested myelæmia [illegible] examination negatives that supposition. Of [illegible] *a priori* possible to say that the child [illegible]ed in the pre-leukæmic stage of myelæmia, [illegible] blood picture of myelæmia was altered [illegible]ion; but the former proposition is sus[illegible]ither proof nor disproof, while there is no [illegible]vour of the latter. Also myelæmia is very [illegible]n. Infantile splenic anæmia is common [illegible]y: many cases thus classified are really [illegible]æmia due to rickets or congenital syphilis, [illegible] there was no evidence of either. On the [illegible] do not frequently come to the post-mortem [illegible]r pathology is obscure we have thought the [illegible]ing. The chief importance of it, however, [illegible] it shows that under suitable stimulation [illegible]mphoid cells of the lymph glands can [illegible]ey do normally in the red bone marrow.

RAPID GENERAL MYASTHENIA GRAVIS.

[illegible]K DODD, F.R.C.S. ENG., &c.,

[illegible]O, AND CLINICAL LECTURER ON OPHTHALMIC [illegible]GERY AT THE ROYAL FREE HOSPITAL;

AND

[illegible] WOODWARK, M.R.C.S. ENG.,
[illegible].R.C.P. LOND.,

[illegible]CAL OFFICER, ROYAL FREE HOSPITAL.

[illegible] this interesting condition it is well [illegible]ry case.

[illegible]ged 25 years, a copying clerk, was [illegible] Free Hospital on Nov. 10th com[illegible]e history of the illness dated back [illegible]y the patient had always been a [illegible] was playing football two days [illegible] about to be described. About [illegible] had "influenza" with bad pains [illegible]ng from his nose and eyes, and feverishness. The attack lasted for about a week but did [illegible] stop the patient from continuing at his work. After [illegible] felt weak and four weeks ago noticed [illegible] chewing his food. His jaw [illegible] he had partaken of [illegible] time he [illegible] later diffi[illegible] at work. When tired his [illegible] his chin touched his ches[illegible] His should[illegible] constantly and he could with difficul[illegible] hold himself erect. Walking fatigued him quickly. Withi[illegible] the last two weeks the patient had noticed dropping of h[illegible] eyelids, the left eye being affected first. Since then he [illegible] not been able to open his eyes fully, this condition pr[illegible]gressing during the day till towards evening he cou[illegible] barely hold them open. As night approached he had diffi[illegible]culty in taking liquid food and said that it had occa[illegible]sionally returned through his nose. Subsequently he notic[illegible] weakness in the hands. Two days before admission [illegible] suddenly became so much weaker that he fell down once [illegible] twice and eventually had to lie down. There was no histo[illegible] of syphilis, alcohol, or pulmonary tuberculosis. There w[illegible] nothing in the family history bearing on the case. When fir[illegible] seen the patient was very pale and rather thin. The face h[illegible] a listless, apathetic, mask-like expression. The jaw w[illegible] generally slightly dropped. There was marked and consta[illegible] ptosis of the left eye and occasionally less marked ptosis [illegible] the right eye. The lower lids always showed two or thr[illegible] millimetres of sclerotic below the cornea. The quality [illegible] the voice appeared to be unaltered. The lips and muco[illegible] membranes were rather pale. There were no enlarg[illegible] glands and his skin was quite normal. There were [illegible] developmental defects of the hands or feet.

An examination of the various systems showed the foll[illegible]ing phenomena:—There were no deformity and no tend[illegible] area in the skull. The superciliary ridges were extreme[illegible] prominent. This, with a somewhat prominent lower j[illegible] gave the face something of an acromegalic appearance. Th[illegible] spinal column showed nothing abnormal. The patie[illegible] could walk, performing the movements correctly but ve[illegible] weakly and soon got tired. When in bed he could only rai[illegible] himself with difficulty to the sitting posture. If he rea[illegible] aloud his eyes, jaws, and hands soon became fatigued in th[illegible] order mentioned, so that his eyelids drooped, he had [illegible] support his lower jaw with his hand, and finally allowe[illegible] the book to fall.

There were no fibrill[illegible] muscles. [illegible] examination of the [illegible] that on bo[illegible] sides the triceps, del[illegible] pectorals were very weak; a[illegible] the supinator longus and biceps fairly good; the inte[illegible]costals acted well, erector spinæ, trapezius, and infraspinat[illegible] weakly, while the rhomboids were fairly strong. The gr[illegible] on both sides was extremely feeble. In the legs no defini[illegible] paralysis of the posterior or anterior tibial groups w[illegible] noticed but both were slightly affected, so that they we[illegible] not as strong as the quadriceps extensor. The adducto[illegible] were weak. All the muscles reacted well to faradism b[illegible] as the examination proceeded the contractions became inte[illegible]mittent and finally ceased. This phenomenon was best se[illegible] in the muscles markedly paretic but was present also to son[illegible] extent generally. The reaction to galvanism was norma[illegible] Coördination and sensation were unaffected. On testi[illegible] the reflexes the plantar response was found to be flexor [illegible] character and occasionally absent altogether. The knee-jer[illegible] were exaggerated but decreased gradually if the attemp[illegible] to elicit them were persisted in. Ankle clonus was prese[illegible] sometimes. The supinator longus and the palate reflex[illegible] were present. Jaw clonus was marked. The lumbar centr[illegible] were unaffected. There was no loss of control over the a[illegible] of defæcation and micturition.

The cranial nerves are best considered *seriatim*. [illegible] Olfactory normal. II. Optic discs normal. The vision a[illegible] visual fields were normal. There was no alteration of colo[illegible] vision and no scotomata were to be found. III., IV., and V[illegible] There were marked ptosis, no squint, and no nystagmus [illegible] any position of the eyes. Diplopia was occasionally com[illegible]plained of. The movements of the eyeballs were incomplet[illegible] the downward movement being better than that in any oth[illegible] direction. The pupils were about four millimetres [illegible] diameter and equal. They reacted to light, accommodatio[illegible] and convergence. As convergence was imperfect the patie[illegible] could read better with one eye at a time than with bot[illegible] V. Sensation over his face was unaffected. The muscle[illegible] of mastication acted feebly and soon became fatigue[illegible] VII. The occipito-frontalis muscle acted pretty well. Th[illegible]

[illegible]. cit.
[illegible]gery, July, 1901.

orbicularis palpebrarum was very weak. The patient could not firmly shut his eyelids but could only just close them and [illegible] show his teeth. When he laughed his face assumed a sneering expression owing to the fact that he only raised his upper lip so that the nasolabial furrow did not extend round the corners of the mouth. VIII. Unaffected. IX. Taste unaffected. X. and XI. The patient had no difficulty in swallowing whilst an in-patient although he gave a previous history of that condition. The muscles supplied by the eleventh were, as stated above, weak. XII. He could only protrude the tongue incompletely. There were no fibrillary tremors.

The respiratory and circulatory systems were normal. A blood count showed 5,300,000 red corpuscles and 9600 white corpuscles per cubic millimetre. The pulse was generally about 80 and the respirations were 18 per minute.

The urinary system was normal; the urine was alkaline, turbid from urates, and contained neither albumin nor sugar. The digestive system was normal and the liver and spleen did not appear to be enlarged. His temperature remained normal or rather subnormal. He lost three and a half pounds in weight during the ten days he was in hospital and left with his condition unimproved. He was treated with the usual tonics, iron, arsenic, and strychnine.

It was a most markedly typical case of myasthenia gravis and showed such a rapid progress that in four weeks from a strong healthy man the patient became so extremely weak that he actually fell and later could not raise himself in bed. The onset of the trouble appeared to have followed an attack of influenza and it is possible that this disease may stand in a causal relation to this case. He appeared to have such a difficulty in feeding himself before he came into the hospital that he felt half starved and this may have added somewhat to his rapid increase in weakness. His mental condition was remarkably good and acute; there were a certain depression of spirits and a tendency perhaps to suspicion. Since leaving the hospital he has been under the care of Dr. T. Battersby Jobson of Ilford, who reports on April 11th, 1905, that "he was little better than he was on leaving the hospital."

A SIMPLE TECHNIQUE FOR THE ENUMERATION OF ORGANISMS IN ANY FLUID.

BY W. H. C. FORSTER, M.B., C.M. EDIN., D.P.H. CANTAB.,
CAPTAIN, I.M.S.

(From the Laboratory of the Pasteur Institute of India, Kasauli.)

CRITICAL consideration of the plating-out method of estimating the number of organisms in fluids such as water, milk, sewage, &c., reveals several disadvantages apart from the inaccuracies inseparable from the method. The two chief disadvantages are the multiplicity of manipulations and the quantity of apparatus required, the result being that in routine work the amount of time expended on the process is altogether out of proportion to the value of the information obtained. It will be readily admitted that in actual practice information as to the source of the sample will often indicate the probable number of contained organisms sufficiently well to save the experienced investigator from much unnecessary manipulation; but, on the other hand, cases not infrequently occur in which such information is either not available or if available will not suffice to guide the investigator in the important question as to the limit dilution to be employed. For example, I have received within a fortnight three samples of stored rain water which contained respectively 100, 1600, and 3,000,000 organisms per cubic centimetre. On the basis of these results a rigid application of the method of plating out, as recommended by the committee of experts appointed by the Royal Institute of Public Health,[1] to future samples of stored rain water would necessitate an expenditure of time and energy which could be more profitably employed in other directions. I would submit that for routine work it will be sufficient if in place of the actual number of organisms per cubic [illegible] 10–100. [illegible] which [illegible] any m[illegible] and in [illegible] plating [illegible] tions a[illegible] siderat[illegible] worker[illegible] devised which will go further and in addition to the above advantages will indicate with an accuracy equal to, if not greater than that of, the plating-out method the total number of organisms per cubic centimetre in terms of 10, 100, 1000, 10,000, 100,000, &c., then a very strong case can be made out in its favour in opposition to the plating-out method as at present practised. I have therefore felt justified in putting before my fellow workers a method of enumerating organisms in any fluid which I have used in routine work for some months past and which seems to me to fulfil the following requirements: (1) Minimum number of manipulations; (2) minimum quantity of apparatus; and (3) accurate estimation of the total number of organisms in terms of 10, 100, 1000, 10,000, &c.

The method in question is not original, being merely a modification of the technique introduced by my former teacher Dr. A. E. Wright for the estimation of the number of living organisms in a given culture and used by him in connexion with his researches on the blood serum. The technique referred to is described in detail by Dr. Wright in his original papers, to which the reader is referred,[2] but in order to give an intelligible description of the modification I have adopted it will be necessary for me to repeat some of the subject-matter of those papers. The method is applicable to the quantitative estimation of bacillus coli, streptococcus, and the spores of bacillus enteritidis sporogenes in sewage effluents in addition to the quantitative estimation of organisms in water, milk, &c., but it will be sufficient for the purposes of description to state the details of the method as applied to the quantitative estimation of organisms in water.

DESCRIPTION OF THE METHOD.

The following is the apparatus required: three sterile diluting pipettes; three sterile watch glasses; eight agar slopes numbered from 1 to 8 consecutively; eight gelatin slopes numbered from 1 to 8 consecutively; and a vessel containing sterile water. The pipette which I use and which I have found to be extremely useful as a general service instrument in the laboratory is graduated differently from Dr. Wright's original model. The stem of the pipette is graduated in ten divisions of five cubic millimetres each, the remaining graduation marks indicating 450 cubic millimetres and 500 cubic millimetres respectively. The safety chamber is dispensed with, the shank of the pipette being merely bent to a right angle in the blow-pipe flame. With the exception of these differences the pipette is constructed and graduated according to the directions of Dr. Wright.

The steps of the operation are as follows. 495 cubic millimetre [illegible] This [illegible] 500 c[illegible] metre [illegible] to be [illegible] pipette—care being taken not to soil the pipette above the five cubic millimetre [illegible] first watch glass. T[illegible] contents of the watch [illegible] the pipette and from this dilution 100 cubic millimetres (obtained by filling twice up to the 50 cubic millimetre mark, interspacing with an air bubble) are planted out in the gelatin and agar tubes numbered 3. Similarly, 10 cubic millimetres are planted out in the tubes numbered 4. From the 1 in 100 dilution five cubic millimetres are then transferred to the second watch glass, giving a dilution of 1 in 10,000. With the same pipette 100 cubic millimetres and ten cubic millimetres of the original water are planted out in the tubes numbered 1 and 2 respectively. (This manœuvre requires a little explanation. If, instead of proceeding as described, tubes 1 and 2 were first seeded and then five cubic millimetres of the original water were added to the contents of watch glass No. 1 it is obvious that this pipette cannot be used to mix the contents of the watch glass without being re-sterilised, as it has been soiled for a considerable portion of its length with a fluid containing spore-bearing organisms.) The first pipette is then laid aside and another one is taken in hand. The contents of the second watch glass are thoroughly mixed and 100 cubic millimetres and ten cubic millimetres are planted out in the tubes numbered 5 and 6. From the 1 in 10,000 dilution five cubic millimetres are transferred to the third watch glass giving a dilution of 1 in 1,000,000. The third pipette is now taken in hand and after thorough mixing 100 cubic millimetres and ten cubic millimetres of this dilution are planted out in the tubes numbered 7 and 8. The whole of the process described can, of course, be carried out with the aid of a single pipette, provided it be sterilised thoroughly in the flame between each dilution. This, however, occasions considerable loss of time and for rapid working three pipettes will be found essential. The remaining steps of the technique will vary according to the wishes of the investigator. Taking either the gelatin or agar series of tubes the quantity of water (in cubic centimetres) planted out will be as follows: tube 1, 0·1; tube 2, 0·01; tube 3, 0·001; tube 4, 0·0001; tube 5, 0·00001; tube 6, 0·000001; tube 7, 0·0000001; and tube 8, 0·00000001. If it is only desired to ascertain the limits within which the number of organisms per cubic centimetre must lie then the tubes are simply incubated in the vertical position and the results are interpreted as follows. Growth in tube 1, but not in tube 2, would place the number of organisms per cubic centimetre between 10 and 100. Growth in tube 2, but not in tube 3, would place the number of organisms per cubic centimetre between 100 and 1000, and so on, the limits adopted being those in general use for the classification of waters by the number of contained organisms. If it is desired to know the actual number of organisms in terms of 10, 100, 1000, &c., it will be necessary to distribute the water planted out over the surface of the medium and to incubate the tubes in the sloping position in order to prevent the accumulation of organisms at the foot of the slope. If preferred the quantity of water planted out may be spread over the surface of the medium with a glass rod but in actual practice I have found this to be unnecessary as in the case of the larger quantities even distribution can be obtained by manipulation of the tube, whilst in the case of the smaller quantities sufficient distribution can be obtained by means of the pipette at the time of planting out. The following three examples will indicate sufficiently well the results obtainable by this method:—

In the quantitative estimation of bacillus coli in sewage effluents one pipette will be sufficient as washing out with boiling water between the dilutions will meet the requirements of the case and the pipette can then be rapidly cooled by washing out with sterile water. With regard to bacillus coli, &c., the special media and methods of incubation used in such cases will, of course, take the place of the ordinary media and methods of incubation used in the mere enumeration of organisms in water.

In conclusion it will be well to consider the advantages and disadvantages of this technique as compared with the plating-out method. The following disadvantages may be urged against the technique:—

1. The diluting pipette being home-made is liable to be inaccurate. I have had a batch of these pipettes tested against a standard one centimetre pipette and it was found that while the relative error as between pipettes was barely appreciable the absolute error in one centimetre was in all cases less than 0·01 centimetre.

2. The method does not admit of microscopic examination of the colonies which develop. This difficulty can easily be overcome by subculture.

Against these disadvantages the following advantages may be set forth:—

1. It relieves the investigator of all anxiety on the score of the limit dilution to be employed when dealing with unknown waters, &c. By the employment of this technique all unpleasant surprises can be avoided. Whether the sample contain 12 organisms per cubic centimetre, or 12,000,000, the number will be estimated with equal accuracy and beyond the possibility of mishaps, such as [illegible] of the plates," "organisms innumerable [illegible] ilution."

2. The technique permits of very rapid working. With the aid of an ordinary coolie I have found that the whole process takes between six and seven minutes.

3. The small quantity of apparatus required.

4. There is practically no waste in this method as all tubes which remain sterile are ready for use again.

5. The pipettes are easily made, inexpensive, and can be sterilised in the flame without fear of breakage.

6. The whole process can be carried out at the water side, a spirit lamp being added to the armamentarium for the purpose of sterilising the pipette.

7. The labour of counting colonies in a Petri dish is entirely dispensed with and consequently all artificial aids to counting, such as counting discs, cease to be necessary.

Kasauli, India.

SEVEN CASES OF BERI-BERI.

By P. N. GERRARD, M.D. DURH., D.T.M.H. CANTAB.,
DISTRICT SURGEON, KRIAN, FEDERATED MALAY STATES.

SINCE my return to the East I have had the opportunity of observing and of carrying out post-mortem examinations upon seven fulminating cases of beri-beri which have occurred in the District Hospital, Taiping. As some of the observations which have been made are of interest and as the disease has of late attracted a certain amount of attention at home it seems to me advisable to publish these cases to the profession in view of the fact that fulminating cases occurring under the conditions of a local epidemic are rare. The cases all occurred in the same ward. All the cases except one occurred in patients who had been for a considerable time under treatment for beri-beri and the one exception was a case which was brought to hospital in the fulminating state but late in the local epidemic, which lasted about one month. All of the patients in the other wards of the hospital, 400 in number, were receiving similar diets to those which were prescribed for the subjects of the cases which fulminated and no patient in the ward where the epidemic occurred who was not admitted in the first instance for beri beri acquired the disease. (There may be one exception to this statement in the case of a Chinese, aged 38 years, who was admitted on Oct. 17th, 1904, for dysentery. He recovered from his dysentery but developed beri-beri which was diagnosed as such on Dec. 3rd.) The majority of the patients in the ward who were not suffering from beri-beri were phthisical. One end of this ward was used as a reception ward for all cases that were admitted to the hospital. In the reception ward the patients remain for about 48 hours and are then transferred to the wards set apart for their respective diseases. No beri-beri has occurred amongst these patients.

CASE 1.—The first case occurred in a Chinese, 53 years of age, who was admitted on August 21st, 1904. He had been nine years in the country and gave a history of having suffered from a disease which was apparently beri-beri for six months. His first bad symptoms occurred on Nov. 14th and he died on the 18th. The treatment of his case was on general principles and no attempt was made to discover the gastric reaction, favourable or unfavourable, to the poison (if such it is) as was done in subsequent cases. He had an iron and arsenic mixture to start with and subsequently, on the increase of his œdema, he was put on a diuretic and when the heart commenced to show signs of failing digitalis was added (Nov. 5th). There were no ankylostoma ova in the stools and until the 14th nothing to excite suspicion of impending crisis in the case arose. On the 14th his pulse was 100° F. and his respirations were 30. He had a pericardial friction rub and the case commenced to fulminate; artificial serum clysters were given twice daily without any relief to the symptoms. The patient died on the 18th at 11 P.M.—that is, three months after his admission to hospital, 96 hours from the commencement of fulmination, and nine months from the commencement of his disease, according to his history.

A post-mortem examination was performed on the day of the patient's death and the most important observation in this case was as usual in connexion with the stomach and intestines. The stomach was dilated and congested with deep purple erosions for a considerable area in the neighbourhood of the pylorus It contained a mucoid fluid in which a bacillus $2 \cdot 8\ \mu$ long by $1 \cdot 05\ \mu$ predominated (Hamilton Wright's bacillus measured from 4 to 6 μ by from 1 to $1 \cdot 5\ \mu$).[1]

CASE 2.—The patient in this case was admitted to hospital on July 15th, 1904. He gave a history of having been ill for two months before admission. He was 25 years of age and had been in the country for three years. During the early days of his stay in hospital he was treated in the usual routine manner with mixtures of iron combined with strychnine and arsenic. On Nov. 21st fulminating symptoms appeared and solution of trinitrin was administered with the object of relieving the right heart; the stomach symptoms were severe, pain and fulness being both complained of, the latter being evidenced [illegible] puffiness. With a view [illegible] the stomach was washed [illegible] of warm water being giv [illegible] of 30 grains of ipecacuanha powder. In view of the possibility of the disease being due to the absorption of a toxin from the alimentary tract the patient was put on a 1 per cent. solution of formalin by the mouth, 15 minims every three hours in water. This proved of no avail; the patient only lived to receive four doses and he died at 1 A.M. on the 22nd.

A point worthy of mentioning in this case is that one of the first symptoms which interrupted the course of what might be described as a chronic case and heralded the fulmination was an extreme tenderness over the splenic area. The abdomen generally was somewhat painful on deep pressure and all the abdominal muscular reflexes were greatly increased. The spleen, however, remained normal in size. The fæcal excretion remained normal throughout; the urine, however, was as usual diminished.

The post-mortem examination, made on the afternoon of the 22nd, showed the following conditions: there was deep congestion of all the mucous membranes, an ounce of fluid was present in each pleura, there was deep general congestion of the lungs, the pulmonary artery was full of dark clot, the pericardium contained four ounces of fluid, and the anterior surface of the heart showed punctiform hæmorrhages. All the other organs were congested and the stomach exhibited a dull reddish-purple interior with considerable erosion which was most marked at the pylorus.

CASE 3.—The patient, a Chinese, aged 23 years, living in the town of Taiping, was admitted into hospital on Nov. 1st, 1904. He gave a history of having been ill for two months. He had been eight months in the country. He was treated at first on ordinary lines—iron preparations, &c. On the appearance of fulminating symptoms, however, which set in on the 21st, I put him on permanganate potassium pills (one grain) morning and evening. Subsequently trinitrin and strychnine had to be exhibited and nitrite of amyl inhalations to be employed. A mustard plaster was also applied over the heart on account of the presence of pericardial fluid. The patient died at 9 A.M. on the 22nd.

The necropsy showed deep congestion of the mucous membranes and of the nails and finger-tips, about an ounce of fluid in each pleura, deep congestions of the lungs, cyanotic enlargement of the liver and the spleen, four ounces of fluid in the pericardium, and the usual severe erosion of the pylorus which extended down the jejunum. This patient had only four grains of permanganate of potassium from the time when it was first exhibited until he died; this was hardly sufficient to expect any rapid result from.

CASE 4.—The patient was a man, aged 45 years, who had lived for 18 years in the country. He was admitted to hospital on Oct. 25th, 1904. Fulminating symptoms showed themselves first on Nov. 24th. At 10.30 A.M. on this day he was in such distress with epigastric pain and dyspnœa that I tried an emetic of ipecacuanha powder followed by warm water in quantity but no emesis took place and gastric paralysis had probably already taken place. At 11.30 A.M. his symptoms became alarming and the engorgement of the right heart clear, so he was bled from the median basilic to ten ounces with relief for about an hour. Strychnine was exhibited and a stimulating mixture of digitalis was administered frequently. The patient died in deep distress at 3.20 P.M. on the same day, the illness having run a very rapid course.

With regard to the post-mortem appearances, there was no rigor mortis such as I have frequently observed in beri-beri cases. Both lungs were intimately "glued" to the chest wall throughout their whole surface, presumably due to acute emphysema, due in turn to a paralytic state of the air vesicles probably, the pericardium contained two and a half ounces of fluid, the heart was enormous, and the surface veins were engorged and dilated. The stomach showed the usual purple erosion, which was most marked at the cardiac end in this case; the condition increased in severity towards the lower end of the duodenum.

A differential leucocyte count in this case at the commencement of fulmination showed: polymorphonuclears, 53·3 per cent.; large mononuclears, 7·3 per cent.; lymphocytes, 33·3 per cent.; eosinophiles, 1·6 per cent.; and transitionals, 4·3 per cent. No malaria parasites were observed.

CASE 5.—The patient, a man, aged 29 years, who had lived for five years in the country and who had been ailing for 20 days, was admitted to hospital on Nov. 24th, 1904. Fulminating symptoms occurred on the 28th and death took place at 9 50 P.M. on the 30th, the crisis having lasted 50 hours. On the 25th he was placed upon a mixture containing creasote and iodoform which I have been giving as a routine mixture in the treatment of beri-beri, with the object of checking gastric fermentation and attempting to heal the erosion which occurs in all these cases. He was also given small doses of a cardiac stimulant and a sudorific. On the 28th he refused to take his medicine, saying that it made him feel "worse," and his obstinacy was so great that although other patients in the ward expressed themselves as "feeling better" on the same mixture I changed it in his case to a stimulating mixture containing carbonate of ammonia, digitalis, and nux vomica. On the 29th he was so ill with distressed breathing and all the usual signs of cardiac engorgement that I commenced clysters of normal saline solution with the object of preventing clotting in the right ventricle and, if possible, of diluting the unknown poison in the blood. On this date the reaction of his fæces was highly acid and vomiting started. Saline enemata (six ounces every three hours) were persisted in without amelioration of his condition and on the morning of his death—namely, the 30th—five days after the premonitory symptoms of crisis (namely, dyspnœa, epigastric pain, fulness, and tenderness, and increase of the œdema, with vomiting), the case assuming a dangerous aspect, he was placed on solution of trinitrin and strychnine injections were administered. The following was his physical condition on that date. The pulse was 128, the respirations were 42, the temperature was 99·8° F., the liver was two and a half inches below the costal margin, the spleen was not palpable, and pretibial œdema was increasing. The amount of urine voided in 24 hours was 27 ounces. As the bowels had been constipated for two days the patient was given as a forlorn hope one minim of croton oil. The vomiting, however, continued and death took place at 9.50 P.M.

---

[1] Studies from the Institute for Medical Research, Federated Malay States, vol. ii., No. 2.

Post mortem marked rigidity was met with, the finger-tips and lips were livid, in the right pleura were found seven ounces of fluid and in the left three and a half ounces, the pericardium contained 16 ounces of fluid which was not diagnosable by percussion 12 hours before death (probably a fulminating hydro-pericarditis—compare the acute emphysema mentioned above), the gall-bladder was distended, the liver was congested, enlarged, and somewhat friable, the spleen was deeply congested, enlarged, and friable, and the kidneys were congested. The erosion was not so marked in the stomach itself, but the pylorus and the first stage of the duodenum were very severely affected. In the intestines patches of erosion occurred with intervals of healthy intestine of from six inches to one and a half inches in length; these erosions occurred throughout the small intestine, and at longer intervals in the large intestine right up to the anus. There was also a subacute appendicitis in this case.

CASE 6.—The patient, a man, aged 43 years, who had lived in this country for 20 years, and who had been ailing for 10 days, was admitted in a condition of pneumogastric crisis on Dec. 4th at 11.30 A.M. He died at 1.15 P.M. on the same day. Nothing could be done for this man as he was nearing dissolution on arrival. I quote the case merely to complete my series.

Post-mortem examination showed rigidity to be only fairly marked. The face, neck, fingers, and lips were almost black. The pleura and lungs were normal, in the pericardium were two and a half ounces of fluid, the heart was large but healthy, there was commencing cirrhosis in the liver, the gall-bladder was full and tense, the spleen weighed one pound and was congested, and the kidneys were congested. There were hæmorrhagic patches about the middle and at the pyloric end of the stomach; these also occurred in the duodenum and intermittently also in the jejunum, becoming more intense towards the lower end; they were very numerous and well marked in the ileum. The cæcum was congested. The first part of the colon was healthy but the erosions occurred again on approaching the lower end as far as the rectum, which in itself was healthy.

CASE 7.—The patient was a Chinese, aged 29 years. He had been resident for a year in the Federated Malay States. The duration of the disease was said to have been one month. He was admitted to hospital on Sept. 20th, 1904; fulminating symptoms developed on the morning of Dec. 23rd and death occurred on the same day. This patient was first placed on a mixture of iron and quassia. On Oct. 7th a stimulating mixture containing carbonate of ammonia and digitalis was exhibited. This proved of no practical benefit to the patient and with a view to determining whether the toxin was more partial to an alkaline or acid reaction in the stomach I put him on a strongly alkaline mixture of soda and carbonate of ammonia on Nov. 29th. The secretion of urine throughout this case was very small, the daily average for the six days commencing Nov. 29th being 12·16 ounces; it contained no albumin but there was a copious deposit of phosphates. On Dec. 8th the urine had diminished to six ounces in 24 hours; he was given a mixture containing iodide of potassium and digitalis and a hot bath twice daily. The stools were examined for ankylostoma ova but without finding any. On the 21st the œdema had become more marked and the general condition of the patient was worse. On the morning of the 23rd the temperature rose to 100·6° F., the œdema was much more severe, and the crisis commenced. The urine averaged for the 15 days previous to this date 8·5 ounces in 24 hours. I made prolonged efforts to save this patient. He was bled to relieve the right heart, the pericardium was tapped to relieve the effusion, and transfusion of saline solution was pushed, but to no purpose, and he died on the operating table with the cannula still in his median basilic vein.

With regard to the tapping of the pericardium in this case I may admit freely that there was more cardiac dilatation than fluid in question and I will also remark that the right ventricle was wounded superficially by my trocar. I would therefore recommend that in future where patients suffering from beri-beri are concerned (in whom the cardiac dilatation may be, and often is, beyond all anticipation in its extent) if the pericardium is to be tapped *let it be by means of deliberate operation*, in which the membrane is to be picked up and carefully punctured in a direction clear of the enormously dilated heart. I would draw attention to the following points in the history of this case: (1) that the urine during the last 15 days of life *was less than the normal amount by 622 ounces*; (2) that the temperature rose at the commencement of the crisis; and (3) that alkaline mixture brought about no improvement.

A post-mortem examination was made within ten minutes after the death of the patient. Rigidity was not yet present; the skin and tissues were very œdematous, the muscles were deeply congested; the superficial veins on the stomach were injected, and the body generally was anasarcous. In the right pleura a small amount of fluid was met with and in the pericardium five and a half ounces of blood-stained fluid had collected. The heart was enormously dilated and flabby (one of the most striking cases of paralytic "jelly-fish dilatation," if I may coin a term, which I have seen); a small puncture on the left ventricle did not penetrate. The liver was congested, normal in size, and the gall-bladder was full (paralysed?); the spleen was slightly enlarged and soft; the right and left kidneys were small and very hard but were apparently normal; the capsules stripped easily; the stomach was small and the mucous membrane was reddened diffusely and considerably thickened; in the intestines there were two patches of [illegible] in the second and third stages of the duodenum and two round worms were found lower down; and there was a patch of marked inflammation in the upper part of the descending [illegible] colon.

In concluding these [illegible] selves they are [illegible] I can safely say, [illegible] beri to some ext[illegible] worthy of note [illegible] classical signs. [illegible] sometimes marked [illegible] increase of abdom[illegible] and to some exten[illegible] diminution in the [illegible] congestion of the [illegible] favour the developm[illegible]. Although only one of these cases exemp[illegible] point, I have, I believe, proved it in many others. 3. That no dilution of the poison in the blood by means of saline clysters or transfusion is possible and that the crisis is, therefore, in all probability a collapse of the nervous system, and the poison may be transmitted purely through nerve tissue. 4. That bleeding is of no permanent value (previously established, I consider). 5. That no alteration of the normal proportions of the leucocytes occurs.

The hospital beds are infested with bugs which are almost impossible to exterminate, owing to faulty construction and the Perak system of blanket bed-covers instead of mats. I have examined microscopically several bugs from the beds of fulminating cases but have found nothing suspicious. I must express my regret that my impending transfer to a district where there is practically no beri-beri will probably interrupt for some considerable time my further remarks upon this disease. I have been obliged thereby to publish these cases in a somewhat rough form but trust that they may be of interest.

Krian, Federated Malay States.

A FATAL CASE OF PRECIPITATE LABOUR.

BY H. E. RAYNER, F.R.C.S. ENG., L.R.C.P. LOND.,
AND
W. L. STUART, M.D., B.S. LOND., M.R.C.S. ENG.,
L.R.C.P. LOND.

FATAL cases of precipitate labour comparable with the following are not unknown, but fortunately they appear to be of sufficiently rare occurrence to justify the publication of this case, which, though it may be described as gruesome in its details, nevertheless presents some points of interest.

A primipara, aged 26 years, had been examined on Feb. 27th, 1905, with the object of deciding the approximate date of her confinement. She had been again seen on May 10th with reference to the advisability of calling in a nurse; no examination was made on this occasion. At the examination in February a vertex presentation was revealed, apparently in all respects normal, fœtal heart sounds indicating a living child. The husband left for his work at 2 P.M.

on the afternoon of May 11th, the woman being apparently in good health and spirits. On his return at 4.30 he was unable to find his wife, but eventually on forcing an entrance to the water-closet he found her seated there apparently inanimate. She was carried to another room and assistance sent for. Restorative measures were persisted in for half an hour but without success, death having apparently taken place some time previously, probably an hour or more before she was discovered. It was then found that the whole contents of the uterus had been ejected into the pan of the closet, the child's head having completely passed through the lower opening, the body and shoulders remaining above. Forcible attempts were then made to extract the child but without success. The passage of the head through the opening had no doubt been due to the force of expulsion aided by gravity; the task of withdrawing it was probably rendered impossible by the subsequent œdema and congestion due to its dependent position, also possibly to extension. Eventually the commode had to be taken to pieces and the earthenware pan forcibly smashed before the dead body of the child could be liberated. The infant was a female of full size, had apparently reached full [illegible] There had [illegible] ut it was of [illegible] accuracy.

An examination of the mother was then made and the following facts were determined. The upper segment of the uterus was intact and fairly well contracted; the lower segment and cervix showed bilateral rupture through the whole thickness of the muscular wall. There were several longitudinal fissures in the vagina involving the mucous membrane and part of the muscle wall. The deeper tissues of the perineum were lacerated but superficially it was intact. Death must have been rapid and had presumably been due to shock from the ruptured uterus and from the sudden great diminution of the intra-abdominal pressure, possibly assisted by hæmorrhage, external and also potentially internal by the congestion of the splanchnic area of [illegible] threatened abortion occurring in the third month of gestation. In addition to this the placenta was found to be thinner than normal and apparently not developed in proportion to the child. This fact combined with the history of the threatened abortion may perhaps indicate that there was in this case a tendency to separation in the placenta and membranes and it seems not unreasonable to suppose that such a separation may have occurred and have acted as the actual exciting cause of the violent uterine contractions which must have taken place to produce so fulminant a birth.

The majority of obstetrical text-books give the causes of precipitate labour as consisting mainly of two factors—namely, increased propulsive force and diminished resistance, or both combined. But the auxiliary propulsive force produced by straining at stool is, after all, only physiological, and in this particular case, the woman being a primipara, the second cause, that of diminished resistance, was certainly not present. It would seem probable that in such extremely rapid cases as the one under consideration some exciting cause to uterine contraction, such as separation of the placenta with intra-uterine hæmorrhage, must occur to act as the reflex stimulus.

A peculiar mental disposition is by some authors stated to be present in the majority of these cases and in this instance it is worthy of mention that the woman was of a peculiarly reserved character. While pregnant she shunned her acquaintances and was averse to the aid of a nurse and to medical examination, and it had even been difficult to con- [illegible] also appears [illegible] itself is this: if the birth had not been fatal to the mother it might have [illegible] (such as interference on the part of the mother) [illegible] to the forces of expulsion and gravity had been used to get it into the extraordinary position in which it was found.

It would be interesting to know whether in any previous recorded cases a history of hæmorrhage in the earlier months had been reported. It is regrettable that a post-mortem removal of the genital tract, with a view to preservation, was refused.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON "RETURN" CASES OF SCARLET FEVER OF UNUSUAL CAUSATION.

By H. CAMERON KIDD, M.B. LOND., F.R.C.S. ENG.,

MEDICAL OFFICER TO THE JOINT ISOLATION HOSPITAL, BROMSGROVE.

A BOY, aged two years, was recently discharged from the scarlet fever ward of the joint isolation hospital at Bromsgrove after a detention of seven and a half weeks. The case had been mild and entirely free from complications throughout. There had been no persistent catarrh of the nose or the throat, no otorrhœa, and no sign of eczema, and the child was to all appearances healthy. Desquamation had proceeded normally. He was isolated and "bathed out" in the usual way, being examined by me on the day before his discharge and by the matron on the morning of discharge. A pimple on the buttock was pointed out to the matron by the nurse who last bathed the child but this was regarded as without significance. Eight days later two other cases of scarlet fever occurred in the house to which the child had returned and in another day or two a neighbour's child also sickened. The medical officer of health, when the new cases were reported, examined the boy and found that he presented a patch of raw moist eczema surrounding the anus and extending for quite one and a half inches towards the buttocks in every direction. The pimple which had been noticed before discharge from hospital had undergone no developme [illegible] learnt that the first signs o [illegible] patch of eczema round the anus [illegible] after the child's return home an [illegible] gressed rapidly until in a few [illegible] se in [illegible] cessary to seek medical advice. [illegible] hospital where he still remains. [illegible] other patches of eczema have developed, one on the leg and the other behind the knee. There can, I think, be little doubt that this child conveyed scarlet fever to others through a moist eczema of the anus which developed after his discharge from hospital, and the case shows the uncertainty which surrounds our efforts to destroy infection.

In the form of inquiry into "return" cases of scarlet fever recently issued by the Society of Medical Officers of Health one query is: "Was there any eczema of ears, nose, or mouth?" In view of this case it appears that we must add the anus to the list of possible sites for infectious eczema after scarlet fever and that the skin disease may develop without any previous warning after as long an interval as eight weeks, and may yet be capable of conveying infection.

Bromsgrove.

NOTE ON THE USE OF CHRYSOIDIN IN HUMAN TRYPANOSOMIASIS.

By SHEFFIELD NEAVE, M.R.C.P. LOND.,

TRAVELLING PATHOLOGIST TO THE SOUDAN GOVERNMENT WELLCOME LABORATORIES.

AT the end of December last I proceeded to Gondokoro in the course of my duties to meet Captain E. D. W. Greig, I.M.S., in order to arrange a joint investigation as to the prevalence of the tsetse fly. Among his caravan arrived from Uganda was a boy, about 18 years old, in the first stage of sleeping sickness. Trypanosomes in number were demonstrated in the juice of the neck glands. Captain Greig was good enough to hand the boy over to me as I had brought up some chrysoidin on the chance of having this opportunity. Dr. A. Balfour of Khartoum had been making some experiments with this substance on mosquito larvæ and bilharzia ova which had been more or less successful and it occurred to me that it might be useful in trypanosomiasis. I at once began injecting chrysoidin hypodermically in small quantity—viz., three-twentieths of a grain—as it had, I believe, hitherto only been given by the mouth and later increased the dose gradually to half a grain. The boy remained at Gondokoro, while I went and came for some time (as he had gonorrhœa and possibly syphilis), and it was in consequence of Dr. C. J. Baker's kindness in continuing the treatment in my absence that it was possible to carry out this experiment. A fortnight after the first injection on examination of gland juice only one trypanosome was found after much searching where many had been found previously. Subsequently Dr. Baker made several examinations and found none between this time and the end of January, when the boy was sent on to me while camping on the Bahr-el-Ghazal. Until the first week in March I remained on the river and injected the patient at first every day but gradually diminished the dose to twice a week and I often examined the gland juice without result. The boy rapidly improved and from the first got fat and only suffered occasional pangs from over-eating.

I made a blood count in February, when the boy was quite well, as follows: lymphocytes, 486; large mononuclears, 61; polynuclears, 442; eosinophiles, 7; and myelocytes, 4; total, 1000. At the beginning of March I had to make a forced march of some 330 miles in somewhat difficult circumstances and the boy only got his injection about once in ten days, also he had hard work and less food, his condition getting lower. On arrival at Khartoum at the end of April I was disappointed to find two trypanosomes (of an altered appearance, possibly due to devolution) in the gland juice and at once commenced to inject him as before. The boy now remains at Khartoum, employed in a hospital, to all appearance fat and well, and I hope to be able to report later that he still remains so. It appears to me that chrysoidin has in this one case controlled the disease, at any rate for a time, more easily than arsenic, trypanroth, &c., and I write this in the hope of inducing others to try it and to report.

P.S.—Since writing the above I have received a letter from Dr. A. Balfour at Khartoum, under whose care the boy is, saying that since the injections have been resumed regularly no trypanosomes can be found either in the gland juice or peripheral blood.

Ingatestone.

THREE CASES OF OTORRHŒA THAT HAD RESISTED LONG-CONTINUED TREATMENT CURED BY OTECTOMY AND IRRIGATION.

By F. FAULDER WHITE, F.R.C.S. ENG.

THE first patient, who was an unmarried female, 55 years of age, had suffered for many years with a discharge from the left ear. She had consulted various medical men, including myself, and had recently been advised by a London specialist to have the radical operation performed. She was sent to me by Dr. H. T. Tomlinson for further advice on account of increasing pain and giddiness. The ear was very offensive. On Nov. 27th, 1904, I performed otectomy. There was little pain or other disturbance. Antiseptic irrigation was carried out twice daily for three weeks when the ear was sweet and the patient left for home. Daily irrigation was, however, carried out by a friend who had been taught to use my attic cannula. Seen in April the ear was quite well, discharge, pain, and giddiness having disappeared some weeks previously. The second patient was a male, 30 years of age. He came to me on Jan. 8th suffering from a very offensive discharge from the left ear. He was still using the remedies of a leading specialist, under whose care he said he had been for about four years. There was a large perforation in the membrane. I performed otectomy on Jan. 22nd. There was little or no disturbance. In less than a fortnight the cavities were disinfected and the ear was well by the middle of February. Seen on May 30th the ear was perfectly healthy and the man could hear a watch several inches from the meatal orifice. The third patient was a boy, 12 years of age. He was sent to me by Dr. W. Richardson Rice for the relief of deafness and otorrhœa which had existed for seven years. On two or three occasions he had seen a specialist who ordered syringing and this had been carried out at home without producing any benefit. On Jan. 15th I performed otectomy in the right ear. Irrigation was carried out daily by Dr. Rice. There was little or no disturbance after operation. There was gradual improvement but it was not till the middle of March that the ear could be pronounced well. Seen in May the ear was healthy and with good hearing.

METROPOLITAN HOSPITAL.

A CASE OF SPINA BIFIDA.

(Under the care of Mr. WALLACE ASHDOWNE.)

FOR the notes of the case we are indebted to Mr. R. I. Douglas, house surgeon.

A female child, aged four days, was admitted to the Metropolitan Hospital on April 12th, 1905, suffering from spina bifida. The tumour, situated in the lumbar region, was of about the size of a Tangerine orange, sessile, and somewhat constricted at its base. The base alone was covered with skin which merged gradually into a translucent membrane. There was a suggestion of lobulation but no umbilication. The summit of the sac was raw, suggesting injury during delivery or rupture of adhesions between the sac and fœtal membranes. There was no deformity of the legs or paralysis and the functions of the bladder and rectum were normal. On the 13th the child was lightly anæsthetised and placed in the prone position with the buttocks raised above the level of the body, so that the tumour formed the highest point. Two skin flaps were dissected from the base of the tumour; an opening was then made into the lowest part and to one side of the sac and the fluid was allowed to escape slowly. This opening was carefully enlarged and the cord was found to be adherent to the upper part of the lining membrane of the sac in the middle line. Two small nerves on each side were found, apparently arising from the end of the cord, running on the inner wall of the lower part of the sac forwards to the spinal column; these had to be sacrificed. The lining membrane of the sac was first separated from it and then divided on each side of the cord and allowed with its nerves to fall back into place in the bony groove of the spinal canal and the cut edges of the lining membrane, apparently dura mater, were sutured with fine silk over them. The rest of the sac was removed and the skin was sutured with silkworm gut over the closed dura mater. A collodion dressing was applied and the child was put back to bed in the position in which the operation was performed. Healing took place by primary union and was uneventful except for a rise of temperature for 12 hours on the second day. On the seventh day the stitches were removed and the line of suture was found to be soundly healed. There was no leakage of fluid from the wound. The child was, when discharged from the hospital on May 12th, in good health and is still progressing favourably.

Remarks by MR. ASHDOWNE.—The fact that the surface of the tumour was damaged and the difficulty of protecting it from further injury, together with the fact that except for the tumour the child was well developed and healthy, led me to decide upon an early operation, and its successful issue is due partly to the skill of the anæsthetist and partly to the favourable anatomical relations of the cord and nerves which allowed of a rapid conclusion of the operation. The membrane to which the cord was attached was easily separated from the sac wall and must have been, I think, dura mater. The nerves which came off from the cord with two exceptions ran forwards across the sac to the intervertebral foramina. No attempt was made to free the cord from its attachment to the lining membrane but a longitudinal incision was made through the membrane on each side and cord and membrane were allowed to fall back into place The two small nerves which ran in the inner wall of the sac were sacrificed but, as far as can be made out at present, with no ill result

KENT AND CANTERBURY HOSPITAL

A CASE OF NEPHRITIS, WITH ACUTE URÆMIA, ASSOCIATED WITH ACUTE DIFFUSE COLITIS, DEATH

(Under the care of Dr HAROLD WACHER)

FOR the notes of the case we are indebted to Dr E Weatherhead, house physician

A married woman, aged 37 years, was admitted on April 4th into the Kent and Canterbury Hospital, under the care of Dr Harold Wacher, with a history of having had no action of the bowels for four days in spite of castor oil and enemata and of having frequently passed blood by the rectum during the last week or two There had been some tenderness and pain about the umbilical region but no abdominal distension and no vomiting

On admission the patient seemed to be somewhat lethargic and would only speak in answer to questions There was some tenderness about the umbilical region but no distension or rigidity of the abdomen The tongue was moist and clean The pulse was 100 and the temperature was normal Rectal examination disclosed nothing The heart and the lungs appeared to be normal About 6 30 the same evening the patient had an epileptiform fit, from which she never wholly emerged She remained semi conscious the whole of the next day (April 5th) and could not be made to take food or medicine The temperature was now slightly raised (from 99 5° to 100 5° F) As no urine was passed a catheter was used and the urine was found to be loaded with albumin Jalap was administered, the patient not refusing the medicine this time, and a hot vapour bath was given The bowels acted during the night a watery motion, slightly stained with blood, being passed into the bed The next day (April 6th) the patient became more comatose Now and then, for a few minutes she would breathe in stertorous fashion, with cheeks blown out with expiration, eyes strongly convergent, and teeth clenched The mouth also twitched at times Any examination of the patient brought on these symptoms In the afternoon she suddenly became convulsed extremely cyanosed, and died

Necropsy —At the post mortem examination both kidneys were found to be deeply congested being bluish in colour pping them off the a slightly granular of the cortex The kidneys were about normal in size and weighed six and a half ounces each The large intestine from the splenic flexure downwards was intensely congested and bluish black in colour No blood was found inside the bowel The mucous membrane had the same bluish black colour with here and there little slightly raised and roughened patches of greyish appearance The whole of the wall of the bowel was very much swollen The rest of the intestines was healthy The remaining organs, including the brain, pre

bowel were sent away e following report was received from the Clinical Research Association "The kidney shows dilatation of the convoluted tubes and a granular condition of the secreting epithelium in certain areas Many of the tubules contain granular and hyaline casts and in several places there is a decided increase of the fibrous stroma The condition is therefore a mixed nephritis with excess of tubal change The large intestine exhibits the effects of an acute diffuse colitis and the greyish patches on the mucosa are due to exudation and necrosis The whole thickness of the wall is œdematous, with many foci of small round cells in the submucosa and destruction of much of the mucous membrane itself "

Remarks by Dr WEATHERHEAD —The following points are of interest in the above case 1 The absence of any œdema throughout the history of the case Without an examination of the urine there would be nothing—until the advent of uræmic symptoms—to suggest nephritis Vomiting was absent throughout and headache apparently was not complained of 2 The occurrence of acute colitis In his article on Nephritis in Allbutt s "System of Medicine"[1] Dr W H Dickinson gives no description of this form of colitis though he makes special mention of an ulceration of the intestine in association with nephritis—"more particularly about the ileo cæcal region"—which is the result apparently of submucous hæmorrhage Dr W Hale White[2] gives instances of acute colitis in association with Bright s disease but says "it is certainly unusual " 3 The mixed character of the renal changes In some respects the kidney presented the appearance of an early stage of chronic interstitial nephritis , in other respects it presented the appearance of acute nephritis Clinically, the case would seem to be an acute one, but there may have been symptoms at some previous time which were not understood The patient was in fact laid up with an illness some months ago, of which it was impossible to obtain any definite account As there was no appearance of hypertrophy of the heart we may conclude that the nephritis was at all events of not very prolonged standing

WEST OF ENGLAND EYE INFIRMARY.

A CASE OF DOUBLE CATARACT EXTRACTION FOLLOWED BY GLAUCOMA IN BOTH EYES

(Under the care of Mr A C ROPER)

THE patient a woman aged 60 years, was admitted to the West of England Eye Infirmary on Dec 9th, 1898 with well marked cataract, nuclear and cortical in each lens The pupils were active and tension was normal There was some dacrocystitis on the left side In July, 1900, the left canaliculus was slit up and the lacrymal condition was energetically treated On Sept 27th, 1900, an uneventful extraction without iridectomy was performed on the left side and on Jan 8th, 1901, a needling of the capsule The result was D V L $+ 10\,D = \frac{6}{9}$, N V L $+ 14\,D = 1$ On Feb 26th of the same year she came to the infirmary again with a typical subacute glaucoma of the aphakic eye which had been treated by her local medical attendant for a fortnight Tension was + 2 The cornea was hazy The pupil was dilated , V = fingers A large iridectomy upwards was performed on the same day with escape of vitreous and much bleeding from the iris On March 7th Mr Roper s note was "No fundus reflex A good deal of blood still in pupil but not enough to account for the loss of fundus reflex Query retinal hæmorrhage " Three grains of iodide of potassium were given thrice daily On the 15th the note was "Media clearing Red reflex to day " The eye steadily improved and on June 7th V L with correction was $\frac{6}{9}$ partly Meanwhile the right lens had become opaque and in view of the glaucoma in the left eye a preliminary iridectomy was performed on March 25th, 1901 On the 29th the right eye had recovered from the iridectomy and the patient was made an out patient She remarked on leaving that the last iridectomy had entirely cured a constant frontal headache which she had suffered fro On July 2nd an ight lens was perfor the 29th with D V $\frac{R + 9\,D = \frac{6}{9}(3)}{L + 10\,D = \frac{6}{12}(4)}$ The left eye was therefore losing vision Mr Roper next saw her in January, 1903, when vision was with spectacles $\frac{R = \frac{6}{60}}{L = \frac{6}{12}}$ The right pupil was covered by a crinkled capsule and both optic discs showed deep cupping The membrane was needled freeing some iritic adhesions and causing some slight hæmorrhage from the iris, and on May 4th the corrected V R was $\frac{6}{18}$ The patient reappeared on Nov 7th, 1904, with glaucoma of the right eye She had fundus reflex but no details were seen She was taken into the infirmary and was treated with eserine, pilulæ hydrargyrum, &c reducing the tension to normal She remained better for three weeks but on Dec 12th the eye became worse The field was small, the cornea was hazy and vision was $\frac{7}{60}$ Treatment failing to arrest the glaucoma Mr Roper determined to excise more iris and this he did on Jan 5th of this year There was of course escape of vitreous but the eye speedily recovered and on Feb 20th the corrected vision was R $\frac{6}{18}$ (2), L $\frac{6}{18}$ Mr Roper last saw her on April 3rd when the corrected vision was

[2] Allbutt s System of Medicine, vol III , p. 942.

R., $\frac{6}{18}$ (2), L., $\frac{6}{18}$ (3), and the fields of both eyes were concentrically contracted to one-quarter of the normal. The eyes were quiet and normal looking and the patient was using a weak eserine drop daily.

Remarks by Mr. ROPER.—The above is a brief abstract of my notes of this interesting case, which is worthy of being put on record. Two points are brought into strong relief—the inveteracy of glaucoma and the remedial value of iridectomy in this condition. The occurrence of glaucoma after cataract extraction must be rare, as I can only recall one other such case in an experience of considerably over 100 cases.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Puerperal Eclampsia.—Repeated Tubal Pregnancy.—Thyroid-like Structures in Ovarian Cysts.—Deformed Fœtus.—Ruptured Interstitial Pregnancy.—Primary Carcinoma of both Fallopian Tubes.

A MEETING of this society was held on June 7th, Dr. W. R. DAKIN, the President, being in the chair.

Captain J. C. HOLDICH LEICESTER, I.M.S., of Calcutta, reported a case of Puerperal Eclampsia with death on the sixteenth day after delivery from general septic peritonitis, due to rupture of an abscess in the spleen.

Mr. ALBAN DORAN reported a case of Repeated Tubal Pregnancy which had twice been under his observation in hospital with clinical evidence of tubal gestation, first on the right side and after an interval of 12 months on the left. Owing to increasing swelling with pain and hæmorrhage the abdomen was opened and clots together with both tubes and the right ovary were removed. The patient was the subject of pulmonary tuberculosis to which she ultimately succumbed 13 months after the operation. Mr. Doran raised the question whether, in view of the possibility of another abnormal pregnancy taking place, it was justifiable in operating for tubal gestation to remove the opposite tube even when healthy. He quoted three cases of his own in which a normal uterine pregnancy had followed removal of a pregnant tube.—Dr. R. BOXALL mentioned a case in which a normal pregnancy and delivery occurred about a year subsequently to removal of a ruptured tubal gestation.—Dr. HERBERT R. SPENCER said that he had operated [illegible] three cases of bilateral tubal pregnancy and in two others [illegible] observed intra-uterine pregnancy after tubal gestation.—Mrs. M. A. D. SCHARLIEB mentioned a case of [illegible]ured ectopic gestation operated on in July last, the patient being now five months pregnant.—Lieutenant-Colonel A. J. STURMER, I.M.S., referred to the case which he had recently brought before the society in which, at the time of operation, the opposite tube was found to be red and swollen but was not removed. A year later it was discovered that ectopic pregnancy had again occurred. He consequently thought that it would have been safer to have removed both tubes at the first operation.—Mr. DORAN, in reply, said that every conceivable variation had been observed in cases of tubal pregnancy—repeated in the opposite side, repeated in the same side, simultaneous in the right and left tubes, simultaneous tubal and uterine pregnancy and, lastly, gestation in a tubal stump. Still, the evidence of those who had joined in the discussion supported his opinion that when pregnancy occurred after the removal of a tubal gestation sac it was, as a rule, normal; hence, when the sac was removed it was not justifiable to amputate the opposite tube.

Mr. R. HAMILTON BELL reported two instances of Thyroid-like Structures in Ovarian Cysts. In both cases the cysts were multilocular and had been removed by operation. They showed in each instance appearances resembling those of the thyroid gland. An explanation was doubtless to be found among the following: (1) metastatic growth from a primary thyroidal carcinoma; (2) secondary growth from a normal thyroid gland or from a simple goitre; (3) growth of a teratomatous nature; (4) endothelioma; and (5) colloid degeneration of an ordinary cystic adenoma of the ovary. He was disposed to regard the last mentioned as the most probable explanation.—Dr. H. WILLIAMSON agreed that in many cases the resemblance to thyroid tissue was brought about as the result of pressure exerted by colloid contents in the smaller loculi, upon the columnar epithelium of an adenoma of the ovary. But, at the same time, he thought it possible that in some cases an explanation was to be found in a teratomatous origin.

Mr. CHARLES SINGER exhibited and described a case of Extreme Ectopia Vesicæ and Congenital Absence of the Colon, combined with other deformities, in a full-time fœtus which had lived for 14 days.

Dr. H. RUSSELL ANDREWS recorded a case of Ruptured Interstitial Pregnancy in the Left Cornu of the Uterus which had undergone early rupture. The period was only six days overdue and the gestation cavity would but just admit the tip of one's thumb. The uterus was removed by supravaginal amputation, both ovaries being left. But he raised the question of the possibility of preserving the uterus in cases like this where rupture took place early, merely excising the affected cornu and suturing together the resulting raw surfaces.

Dr. C. J. CULLINGWORTH showed and described specimens of Primary Carcinoma of both Fallopian Tubes which he had removed by operation from a woman 41 years of age. For two years previously she had had almost continuous pelvic discomfort, with frequency of micturition and a constant and increasing watery discharge sometimes blood-stained and frequently offensive. The diagnosis was obscure. A month's rest in bed having been followed by no apparent benefit operation was decided upon. When the preliminary enema was given about a pint of bright blood was passed by the bowel and under anæsthesia a small fistulous opening was felt in the rectum four inches from the anus. On opening the abdomen both tubes were found to be affected with malignant disease, the left being much the larger but the uterus was of normal size and no extension of the disease to other parts in the abdomen could be felt. There was no ascites. It was thought that the fistulous opening into the bowel would supply [illegible] drainage. Subsequently some difficulty was [illegible] ing the bowels to act. The patient died [illegible] the operation.—Mr. DORAN thought [illegible] that the cancer had developed, as is often the case, in an old hydrosalpinx.

OPHTHALMOLOGICAL SOCIETY.

Cribriform Choroido-retinitis.—The Question of Visual Efficiency.—Subsequent note on a case of Orbital Tumour.—Against the Use of Strong Applications in the Treatment of Ophthalmia.—Subsidence of Optic Neuritis after Removal of Cerebral Tumours.—Ring Sarcoma of the Uveal Tract.—Exhibition of Cases and Specimens.

A MEETING of this society was held on June 8th, Mr. JOHN TWEEDY, the President, being in the chair.

Mr. R. W. DOYNE and Mr. SYDNEY STEPHENSON contributed a note on Cribriform Choroido-retinitis, a Rare Form of Fundus Disease. They described three cases in adult patients of a peculiar clinical type of choroido-retinitis, characterised by large membranous sheets of white exudation lying in the fundus beneath the retinal vessels, and showing few or many round or oval holes, through which the colour and markings of the underlying choroid could be recognised. In some instances the holes might be filled with pigment. There were grounds for thinking that the affection had resulted from acquired syphilis. They rejected the view that the condition of the fundus was the outcome of the metamorphosis of copious hæmorrhages.

Mr. G. A. BERRY (Edinburgh) contributed a paper, which was read by the Secretary, on the Question of Visual Efficiency, in which he suggested a graduated scale representing partial loss of sight for guidance in allotting compensation and awards by insurance societies.

Mr. F. RICHARDSON CROSS (Bristol) [illegible] sequent Note on a C[illegible] exhibited before [illegible] Krönlein's operati[illegible] recovery of the pat[illegible]

Mr. W. E. CANT [illegible] Use of Strong Appl[illegible] Treatment of Ophthalmia. In the East there were a great variety of regular and irregular practitioners dealing with the prevalent cases of ophthalmia, some of whom used solutions of nitrate of silver, 80 and 60 grains to the ounce, which did considerable damage to the cornea and conjunctiva. He thought a strength of 10 or 15 grains to the ounce the utmost that should be employed.

Mr. **LESLIE J. PATON** read a paper on the Course of Optic Neuritis and its Subsidence after Operation in cases of Cerebral Tumour. The present paper was the result of an analysis of a series of 105 cases of cerebral tumour at the National Hospital, Queen-square, during 1903 and 1904. 20 of these cases showed no optic neuritis; 38 of the remaining 85 were not operated on. Of the 47 cases operated upon 17 died shortly after operation or were never in a condition allowing of proper examination. There remained 30 cases in which it was possible to examine more or less fully the eye conditions subsequently to operation. As regards visual acuity it was found that the cases fell into four main classes: 1. The visual acuity practically unaltered during the whole course of the neuritis or only very slightly diminished. This class included eight cases. 2. The visual acuity markedly reduced at the time of operation, in some [illegible] classes: (*a*) those which were practically blind at the time of operation and which regained no vision (six cases) and (*b*) those in which the vision failed markedly despite operation (two cases). A total of eight cases out of 30 in which operation did not save sight. 4. Three cases in which one eye retained good vision and the other became blind or nearly so. Out of a total of 30 cases good vision had been saved in 22. In none of the cases in which the sight was lost was the optic neuritis more severe than it was in some of the cases in which perfectly good vision remained. A subjective symptom in cases of cerebral tumour was transient dimness of vision. This occurred in six of the cerebellar cases in the present series, in two frontal cases, in one parietal case, an [illegible] nother series of [illegible] our it occurred [illegible]. The occurrence of this phenomenon so frequently in cerebellar [illegible] onger [illegible] sually [illegible] head- [illegible] er by [illegible] with [illegible] change in the optic nerves, but it might, of course, be due simply to a temporary increase in the intracranial pressure causing a temporary strangulation of the optic nerves. Subjective phenomena of a positive character only occurred in two cases. An examination of the relationship of visual loss to site of tumour showed that the five cases of frontal tumour belonged three to Class 1, one to Class 2, and one to Class 4. In 11 cases of parietal tumour four belonged to Class 1, three to Class 2, one to Class 4, and three to Class 3—i e., where sight was lost. Out of 11 cerebellar cases one came into Class 1, six to Class 2, and four to Class 3. The only pontine case belonged to Class 3. The optic neuritis commenced by inc[illegible] of the upper and [illegible] veins. The blurring [illegible] and then to the outer margin, the central cup filled in, the veins became more turgescent, the smaller vessels on the disc usually invisible filled up, and a condition of steep-edged swelling of a somewhat striate and juicy appearance characterised the completion of the first stage of the optic ne[illegible], of all small and linear [illegible] of the disc, appeared. [illegible] ger and more scattered. [illegible] frontal and parietal tumours was from three to five dioptres, and in cerebellar cases from five to seven dioptres. Later patches of whitish exudate appeared on the disc and in the neighbouring retina. Macular changes only appeared in a small proportion of cases, five in this present series of 30, one in a case of frontal tumour, one parietal tumour, and in three cerebellar cases. The macular change was of a fairly definite type, a layer of œdema forming a kind [illegible] horizontal parallel lines. They lay in the superficial layers of the retina. When there was more extensive œdema of the [illegible] from the fovea [illegible] hanges was not [illegible] with vision—another point in favour of its being superficial, since it did not seem to interfere with the percipient layers of the retina. At the time of operation the intradural tension was noted to be definitely high in all the cases. The subsidence of the swelling was fairly steady in all the cases, usually taking about two months. In some of the cases, especially when the tumour was cystic, it was much more rapid. In the cases which went on to blindness the disc assumed an opaque papery-white appearance as the swelling subsided and in all these cases the arteries were markedly diminished in size. In the other cases where sight was retained the disc had usually a muddy [illegible] that there ever had been an attack of optic neuritis. In one case in which there had been [illegible] vision was $\frac{6}{6}$ in each eye and all [illegible] degree of macular change w[illegible] pigmentation at the macula in one eye and in the other the same pigmentary disturbance at the macula and a small cluster of bright white dots above and to the inner side of the macula.—Dr. **J. S. RISIEN RUSSELL** said that as regards saving sight, even where it was impossible to localise or to remove the tumour, trephining and opening the dura mater so as to relieve pressure were effective.—Mr. **R. MARCUS GUNN** said there appeared to be no relation between the degree of neuritis and the size of the growth. Prognosis based on the locality of the tumour would still require a larger series of cases. He referred the temporary eclipses of vision to increase in intracranial tension with pressure on the optic nerve fibres.—Mr. **DOYNE** mentioned a case of intracranial tumour growing from the left wing of the sphenoid in a woman, aged 30 years, occluding the optic foramen and causing blindness without fundus change on the same side but optic neuritis on the right side.—Mr. **PATON**, replying, attributed the temporary loss of vision to distension of the infundibulum due to intracranial exudation pressing against the chiasma. It specially occurred in cerebellar cases which involved obstruction to ventricular circulation.

[illegible] anterior chamber in its whole circumference. The patient, a lad, aged 18 years, noticed the failure in the sight of his right eye nine months before he was seen by Mr. Werner; he also observed that black spots were beginning to form on the iris. On examination the iris was observed to be covered with coal-black patches of pigment, least marked above; there was also a small brown tumour wedged into the angle of the anterior chamber at the outer side. The anterior chamber was deep, although the tension was + 1. The pupil was slightly dilated and there was a deep glaucomatous cup. The boy could only distinguish the motion of the hand before the eye. The eye was enucleated and the [illegible] unpigmented cells in alveoli. At the upper and lower margins it extended into the ciliary region and sent flat extensions on to the surface of the iris. The rest of the circumference of the angle of the anterior chamber, and of the ciliary body close to it, was infiltrated with deeply pigmented cells and also clusters of unpigmented cells. The ligamentum pectinatum was choked with pigment cells which extended into the canal of Schlemm and along the perivascular lymph spaces of the anterior ciliary vessels. The surface of the angle was lined by black cells, in a single row, or in a condition of active proliferation, the latter especially below. A large quantity of round pigmented cells which had become free were deposited at the bottom of the anterior chamber. When bleached some of them contained shrunken nuclei but in others the nucleus was normal and sometimes two nuclei were visible. The pigment layer on the iris was either confined to the surface where it taken without effect. Bromide and hyoscyamus were the best combination for nocturnal restlessness but sulphonal and paraldehyde were the most successful drugs for the insane, the latter having the advantage of being a heart stimulant. When the usual hypnotics failed it sometimes became necessary to resort to a general anæsthetic. With reference to feeding, when the patient absolutely refused food it was necessary to feed by tube either nasally or orally, as it was a most important factor in successful treatment of insanity that nourishment should be given. Dr. Stoddart concluded his paper by enumerating the means of procedure in sending a patient to an institution.—The President thanked Dr. Stoddart in the name of the society for his paper and corroborated his remarks with reference to treatment, particularly impressing upon the members the imprudence of recommending travel in cases of acute mental disorder.—Dr. S. D. Clippingdale referred particularly to cases of anorexia nervosa occurring in private practice, in which cases it was very difficult to carry out the nasal or oral feeding, and suggested rectal alimentation as being more suitable and better tolerated.—Mr. A. B. Kingsford questioned the advisability of administering hyoscine hypodermically in cases of *acute mania. He found that hyoscine given by the mouth* appeared to be of great benefit and to give quiet sleep, whereas given by hypodermic injection it caused an alarming degree of depression.—Dr. H. P. Potter, in comparing the methods of feeding, expressed his opinion that oral feeding carried out slowly and carefully was the most advantageous.—Dr. H. Campbell Pope spoke of urethane as being a most valuable hypnotic in some cases. He also mentioned an important condition of the urine in so-called cases of neurasthenia—namely, upon using Fehling's test a dark discolouration was found, followed by a black precipitate, probably sulphide of copper.—Dr. Stoddart made a few remarks in reply.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on June 2nd, Mr. C. J. Symonds, the President, being in the chair.—Mr. H. S. Barwell showed a case of Nasal Tuberculosis and a case of Lupus of the Larynx and Uvula.—Dr. G. C. Cathcart exhibited a case of Multiple Growths in the Epiglottic Region in a man, aged [illegible]3 years. These were considered to be growths of the lingual tonsil.—Dr. Atwood Thorne showed a girl, aged 17 years, with Complete Paralysis of the Left Vocal Cord associated with Dilatation of the Left Pupil, Mitral Stenosis, and Hypertrophied Left Auricle.—Mr. P. R. W. de Santi showed a case of Inspiratory Dyspnœa in a woman and Dr. H. L. Lack a specimen of Adenoids removed from a man, aged 59 years.—Other cases were shown by Dr. W. H. Kelson, Dr. air Thomson, Dr. Lack, and Dr. R. H. Scanes Spicer.

Reviews and Notices of Books.

The Law relating to Factories and Workshops. By MAY E. ABRAHAM (MRS. H. J. TENNANT), formerly one of Her late Majesty's Superintending Inspectors of Factories; and ARTHUR LLEWELYN DAVIES, of the Inner Temple, Barrister-at-law. Fifth edition. London: Eyre and Spottiswoode. 1905. Pp. 414. Price 5*s*.

THE law relating to factories and workshops is not summarised by the three Acts of Parliament known as the Factory and Workshop Acts but is contained in these with about 20 others, and in a large number of Orders and Regulations made under their authority. Consequently anyone who wishes to have access to the knowledge of this branch of the law necessarily has recourse to a text-book. He need not be a lawyer in order to require to be informed quickly and accurately upon such a subject. A very large number of persons are directly concerned by the Factory and Workshop Acts in a manufacturing country and ignorance of the law is no defence for him who is accused of breaking it. Medical men are most directly interested in this branch of the law when they hold appointments connected with its enforcement, such as those of medical officers of health and of certifying surgeons, and it is to these especially that a handbook at a moderate price, which contains practically all that they need know, is likely to be useful. It is essential that such a work should be "up to date," and the fact that this volume, jointly written by a lady factory inspector and a barrister, has been republished four times since 1896 shows that the authors have taken care to make it so. The statutes which are new since 1902, the date of the last edition, are not of great importance, but include the Shop Hours Act, 1904, the Shop Clubs Act, 1902, and part of the Employment of Children Act, 1903. This last is one under which any medical man may be applied to with a view to determine the fitness of a child for any specified occupation, and so may be said to be of some direct interest to the medical profession apart from its influence upon the health of the younger section of the population. The new Orders and Regulations since 1901 refer in some cases generally to the sanitary conditions under which work is to be done and in other instances are framed as protections against the inherent dangers of particular processes of manufacture. Medical men *not holding appointments of the class indicated above* have but little liability under the law so far as the health of factory workers is concerned, beyond that of notifying cases of poisoning by lead, phosphorus, arsenic, or mercury, or of anthrax contracted in factories or workshops, to the Chief Inspector of Factories at the Home Office. Medical men holding appointments such as those referred to have to know the law relating to their work intimately and if these are already acquainted with the volume under review from previous editions they do not require that it should be recommended to them. Those who have not before met with it will find it a convenient and well-arranged text-book, not too bulky and certainly not expensive, consisting of two parts: I. A Practical Guide to the Law and its Administration by Mrs. Tennant; II. The Acts, with Notes, by Mr. Llewelyn Davies, and an appendix with the Regulations for dangerous trades and the Orders of the Home Secretary. A full and clear index by the use of figures of different sizes distinguishes between information conveyed in the explanatory Part I. and that which is supplied in the words of an Act or Regulation in Part II.—a very convenient plan.

Electro-diagnosis and Electro-therapeutics. By Dr. TOBY COHN of Berlin. Translated from the second German edition by FRANCIS A. SCRATCHLEY, M.D., of New York. London and New York: Funk and Wagnalls Company. 1904. Pp. xiii.-280.

THIS book is written as a guide to students and practitioners who are taking up medical electricity more or less seriously. There is no doubt as to the excellence of the author's method of teaching the subject and it will be sure to commend itself to the readers of the work. The technical part is dealt with in a very brief yet effectual manner, avoiding confusing calculations and complexity of apparatus, which only serve to discourage the beginner. The chief principles are first explained and made clear with a few simple diagrams. Then follows a description of a simple galvano-faradic outfit, also accompanied by a few diagrams to show the different arrangements of circuits. The author then passes to the physiology and the methods of investigation. Under the latter heading the directions are laid down in a most careful and painstaking manner, and it may be said truly that he who reads may easily learn. The plates showing the motor points deserve special mention. Instead of being placed all together at the end of the book, as is so often the case, each is placed next that part of the text referring to it. The motor points are shown on a schematic figure drawn on transparent paper. Under this is found a plate illustrating the muscles referred to. These plates are adapted from Quain and [illegible] muscle plates. In this part the normal reactions of all the superficial nerves and muscles are given in detail and the pathological changes are dealt with in the same manner in the following chapter. This first part of the volume takes up nearly two-thirds of the whole, the author's contention being that anyone who commands a knowledge of electrodiagnosis can quickly and easily comprehend the electrotherapeutic technical terms, while without such knowledge he learns these terms with great difficulty or not at all. The rule all through is not to confuse the beginner by mentioning innumerable possibilities and variations but rather to represent types which can be easily comprehended and retained. At the end of the book are chapters on other forms of apparatus, static electricity, and Tesla or high-frequency and other forms of constantly varying currents.

The translator is to be congratulated on his share of the work. It is perhaps a fair criticism that he should have kept more closely to the standard anatomical nomenclature and it is difficult to see what good end is served by adopting phonetic spelling in the case of a few isolated words. On Plate III., after indicating the superficial muscles and nerves of electrical importance from the shoulder to the hand, with their *Latin* names, the last of the series is referred to as the "little finger-ball muscles," which is slightly incongruous. These are, of course, mere details and if not adding to its attractions they do not impair the value of a book which is to be commended for its many points of excellence.

A Text-book of Practical Gynecology. By D. TOD GILLIAM, M.D. Illustrated with 350 engravings, a coloured frontispiece,, and full-page half-tone plates. Philadelphia: F. A. Davis Co. 1903. Pp. 634. Price, extra cloth, $4.00 net; half morocco, $5.00 net.

IN the introduction to this work the author calls attention to the large part played by the late Professor Marion Sims in the evolution of gynæcology. According to Dr Gilliam America claims not only the distinction of giving birth to this great and beneficent specialty but has maintained her position in the front rank of discovery and operative technique. We imagine that no one would be prepared to deny that in the production of text-books America still leads the way. Unfortunately, although the amount of work produced by American writers is great, the same cannot always be said of its quality. The present book is a good example of the class of work which possibly finds its appreciators amongst American students but there are many better works on gynæcology in the English language. The style in which the book is written can be exemplified by the following quotation. Dr. Gilliam in pointing out the difficulties which the student at first experiences in acquiring a familiarity with the various methods of pelvic examination compares it to "seeking the middle ounce of mush in a kettle of mush"! It is hardly necessary for us to notice this text-book at any length. Importance is laid on the large part played by a supersensitive condition of the nerves as a factor in the causation of the pain in dysmenorrhœa. In endeavouring to account for the relationship between dysmenorrhœa and anteflexion of the uterus the author tells us that in these cases the endometrium is attenuated and devoid of succulence and is wanting in lymphoid elements. We wonder what is meant exactly by a succulent endometrium? In performing the operation of ventrofixation Dr. Gilliam brings the two round ligaments out on either side through a puncture in the fascia, muscle, and peritoneum (about three-quarters of an inch from the edge of the abdominal incision) and fixes them in this position with a catgut suture, the skin and the fat being meanwhile drawn aside. By this means he claims that better results are obtained than by the ordinary operation. In the chapter on Ovarian Tumours a most interesting case is recorded in which the author successfully removed a cystic tumour of the ovary weighing 176 pounds, the largest tumour ever operated upon with success in Europe or America.

A Manual of Fever Nursing. By R. W. WILCOX, M.A., M.D., LL.D., Professor of Medicine in the New York Post-Graduate Medical School and Hospital; Consulting Physician to the Nassau Hospital. Illustrated. Philadelphia: P. Blakiston's Son and Co. 1904. Pp. 236. Price $1.

THIS volume contains the lectures on fever nursing which were delivered to the nurses at St. Mark's Hospital during the session 1903-04. Dr. Wilcox has selected the material for his lectures with great judgment and discrimination. He has included in the lectures all that nurses should and ought to know, but has wisely refrained from giving any directions as to diagnosis or treatment which might tempt nurses to try to become amateur doctors. The earlier chapters of the book are devoted to a consideration of the general aspects of "fever" and the methods of taking and noting temperatures; then a good description is given of the modes of reducing temperature by means of baths. Nurses may read these remarks with profit. Practical demonstration is undoubtedly of more value than verbal description but many useful hints are here given which nurses will do well to observe. It will be noticed that when writing on "the cold tub bath" Dr. Wilcox remarks: "Vigorous rubbing of the body by the hands of the attendants throughout the bath is an absolute necessity." The combination of massage with cold baths when given for typhoid fever is more frequently practised in America than it is in this country. The various fevers are then considered in detail, information being afforded under the following headings: definition; causation; course and symptoms; varieties; complications; prevention and treatment, including dieting. Directions are given in simple but precise language and the manual can be cordially recommended to all nurses, for in it will be found useful instruction which they may not have opportunities of obtaining whilst receiving their training in general hospitals.

A Text-book of Diseases of Women. By BARTON COOKE HIRST, M D. With 655 illustrations, many of them in colours. London, Philadelphia, and New York: W. B. Saunders and Co 1903. Pp. 683. Price 21*s* net.

THIS work has been written by Professor Hirst as a companion to his text-book on Obstetrics and is the result of 20 years' experience. The author has followed an anatomical rather than a pathological classification as more logical and convenient. The volume, consisting of some 683 pages, is divided into 12 parts. The first part deals with the examination and the local treatment of the patient. The next section deals with anomalies of development in the genital tract. In discussing true hermaphroditism no mention is made of the latest work on the subject with which the author appears to be unacquainted. Part III. deals with the diseases and injuries of the vulva and contains a number of very good illustrations and a very detailed account of coccygodynia.

In discussing complete rupture of the perineum the author mentions the interesting fact that he has appeared in one year as an expert witness in three suits brought for malpraxis as the result of the occurrence of this injury For the palliative treatment of a cystocele Professor Hirst recommends that a Gehrung's pessary should be employed but as he mentions, and as we have found, this pessary is easily displaced and is very liable to set up ulceration of the anterior vaginal wall. In the operative treatment of this condition the author recommends very strongly that the so-called anterior vaginal sulcus on either side should be denuded and sewn up as well as the removal of an oval area of the mucous membrane of the vaginal wall in the usual way. By this means he claims that a more permanent and better result is obtained. The various methods of repairing tears of the pelvic floor are well described and if we may judge by the photographs reproduced of some of the cases operated on by the author the results obtained are exceedingly good.

It is much to be regretted that there is not a greater unanimity of opinion amongst writers on gynæcology as to the best classification of the different kinds of carcinoma. In this work we find the terms epithelioma, squamous-celled carcinoma, medullary carcinoma, scirrhous cancer, and malignant adenoma all used without any real distinction being made between them. The multiplicity of the terms used by various writers in discussing cancer of the uterus leads to great confusion on the part of students. The microphotographs illustrating this section are very poor indeed and we are surprised that the author has reproduced such inadequate illustrations. They are worse than useless and only mislead the student. In the operative treatment of cancer of the uterus the combined vaginal and abdominal operation of hysterectomy with as wide removal as possible of the connective tissue round the cervix is recommended. Of late Professor Hirst has employed the electro-thermic angiotribe to divide the tissues of the broad ligament. In this way outlying nests of cancer cells are likely to be destroyed and the risk of implantation of portions of the growth during the operation is much lessened.

In the treatment of bad cases of prolapse Professor Hirst has obtained good results by the performance of anterior colporrhaphy combined with amputation of the cervix and an extensive posterior colporrhaphy. He finds that after this operation the ultimate result is satisfactory and he is somewhat surprised at the number of failures recorded by various European operators. As an operation for the removal of fibroids panhysterectomy is not recommended, for, as Professor Hirst points out, supravaginal amputation of the uterus is to be preferred as an easier and quicker operation with less risk of injury to the ureters and leaving a more natural condition of the vaginal vault. He reserves complete removal of the uterus for cases of malignant disease, for cases of infection of the tumour or of the uterus, and where it is desired to drain the pelvis by way of the vagina. In considering the treatment of inflammatory conditions of the tubes great stress is laid by the author on the good results to be obtained by prolonged palliative treatment. At the present time when operative gynæcology is so much the vogue some of the younger school of gynæcologists are likely to forget how much can be done for such patients without operation by rest and local treatment, and we are glad to see Professor Hirst lending the weight of his authority to this view. He is also strongly in favour of the retention of a part of the ovaries whenever possible and does not believe that the uterus should be removed when the ovaries are on the ground that it is in these conditions a useless organ. The section on tumours of the ovary is a good one and so is that dealing with the diseases of the bladder. The last 100 pages or so are devoted to an account of the details of the operations recommended in the body of the work.

The illustrations are very numerous and some of them are good. The microphotographs are disappointing and most of them show very little. We were much interested in Plate 8 which is described as showing mucous polyps (*sic*) of the cervix. A series of the wax models from which the plate is taken exists in one of the hospital museums in London and is well known to us. As a matter of fact, three of the models represent a fibroid polypus of the cervix and one of them a vascular sessile growth arising from the vaginal aspect of the cervix, certainly not a mucous polypus. The description of the plate is therefore most inaccurate. No doubt this is a small matter but of importance as an instance of carelessness easily avoided and an error which does not tend to increase our confidence in the author's general accuracy.

The book contains some striking instances of the American method of spelling ordinary English words. However, in spite of this blemish—a very annoying one to the eyes of English readers—and of the defects to which we have alluded, the work may be described as containing much that is of value and interest.

LIBRARY TABLE.

Tables for Qualitative Chemical Analysis, Arranged for the Use of Students. By A. Liversidge, M.A., LL.D., F.R.S. Second edition. London: Macmillan and Co. 1904. Pp. 126. Price 4*s.* 6*d.*—We are glad to find that Professor Liversidge deprecates the far too common plan of allowing the student of practical chemistry to continue mechanically to test mixture after mixture without being required to give evidence of the meaning of the reactions. This is always the danger involved in tables of systematic schemes for qualitative chemical analysis. Analysis by chart is seldom satisfactory inasmuch as the student who is training merely for examination purposes is sorely tempted to take a short cut. So long as he is able to discover what the unknown salt is he gains his immediate object but he may be left with a very unintelligent idea of the rationale of the scheme. Professor Liversidge introduces his subject with some wise words of which the student would do well to take heed. Though we can find no particular novelty in regard to the treatment of the subject yet the author has taken pains to give a satisfactory scheme and to include the characteristic tests of most of the ordinary substances known to chemistry. The sections on organic substances are decidedly good.

The Maintenance of Health in the Tropics. By W. J. R. Simpson, M.D. Aberd., F.R.C.P. Lond., Professor of Hygiene, King's College, London. London: John Bale, Sons, and Danielsson. 1905. Pp. 118. Price 2*s.* 6*d.* net.—This handbook on the maintenance of health in the tropics has been written at the request of the Committee of the London School of Tropical Medicine and is published under its auspices. The author divides it into six chapters which deal successively with climate; diet and drinking water; the dwelling house; illnesses of the tropics and their prevention; snakebite; and wounds. 40 pages are devoted to the prevention of malarial fever and other diseases spread by mosquitoes, the directions given on these questions being very practical. At the end of the work there is a list of necessary medical equipment. The advice given throughout is sound and is set forth in clear and simple language. The book is illustrated in a useful way and will be of service to those residing in, or visiting, the tropics.

Manual of Diseases of Children. By James Burnet, M.A., M.B. Edin. Edinburgh: E. and S. Livingstone. 1905. Pp. 406. Price 6*s.* 6*d.* net.—This manual comprises a brief outline of the diseases of infancy and childhood. Theoretical discussions and morbid anatomy find no place in the volume. Brief considerations of diseases of the skin and also of the nose, throat, ear, and eye are included. The book is valuable so far as it goes and it is written in a clear and straightforward way but on many questions the information is insufficient for the practical treatment of cases. However, the study of the volume will serve to lay a good foundation for further reading and observation on the subjects of which it treats; this is the author's hope. Eight plates illustrate the volume. Students will find the book useful.

Mucous Membranes, Normal and Abnormal, including Mucin and Malignancy. By W. Stuart-Low, F.R.C.S. Eng., Assistant Surgeon to the Central London Throat Hospital. London: Baillière, Tindall, and Cox. 1905. Pp. 60.—The substance of this carefully thought out monograph was originally given as a lecture at the Medical Graduates

College and Polyclinic. Those who make an attentive study of the nature, functions, and probable ulterior destiny of mucin will admit it to be of the first importance in the animal economy. Mr. Stuart-Low says that "one of the most important actions of mucin, and one which has hitherto been altogether overlooked, is as a bactericide." It is evident that mucin fills a potent part in the defence of the body against bacterial attack. Dust and microbes do no harm if they fall on healthy cutaneous structures, nor can they do much harm by impinging on sound mucous membranes; but, falling on impaired tissues, great havoc and disaster may follow. With regard to the possible relation between mucin and malignancy the author writes: "I have now carefully observed for years a large number of cases of malignant disease and have never yet seen one that was not decidedly hypomyxiatous and that had not been so for years previously." ...... "Normally, there is always a layer, however thin, of mucigenous material which separates the constituent cells in every tissue and membrane throughout the body; in carcinoma, however, the cells are not thus isolated but touch one another. Has this no causative significance? In old age the intercellular material undergoes a wasting change and, as a result, its resistive power against the ingrowth of epithelial cells is lessened and the onset of carcinoma is favoured." ...... "A study of the distribution of mucus-manufacturing structures reveals the striking fact that where mucus normally is least abundant malignant disease is most frequently located." He is inclined to believe that the hypomyxiatous state is a forerunner of the cancerous, especially in view of the fact that three-fourths of all cancer in man occurs in the alimentary canal. The topical application of mucin in carcinoma certainly retards growth, soothes, and has a marked cleansing effect. The author is indebted to Dr. Walker Overend for the nomenclature which indicates the changes that may occur in mucus and mucous membranes in the diseased conditions. He is inclined to believe that orthomyxia is conducive to healthy old age and he has not seen one healthy old man who was not orthomyxiatous. We have read this brochure with considerable interest. The author's views are very clearly and practically stated. He remarks that if practitioners will apply the principles arrived at from this study they may "gain a rich return in their daily medical practice."

JOURNALS AND MAGAZINES.

IN *Medical Electrology and Radiology* for May an editorial article deals with a circular—which is printed in full—issued by the governors of Guy's Hospital to the effect that they are prepared to accept paying patients for treatment by Finsen light, x rays, radium emanations, high-frequency currents, static, faradic, and galvanic electricity, and vibratory massage. They offer by way of an excuse for this procedure that they "are anxious to recoup themselves for the many expenses incidental to the maintenance of this large department in which poor cases are treated free, but they are desirous that paying patients should only attend upon the recommendation of a general practitioner." In his comments the editor says that this "action of Guy's Hospital surely raises the vexed question of unfair competition on the part of the charitable institution with the practitioner. There are many medical men who are proficient in this work and have adequate apparatus who would be glad to take patients on the terms proposed in the circular. ...... Moreover, if this principle is admitted it is equally logical to have surgical consultations followed if necessary by operation at an arranged fee, on the plea that the furnishing of the operating theatre has cost the institution so much that some return for the money expended must be sought. ...... It is much to be hoped that the governors will find it expedient to withdraw this scheme which, though promulgated doubtless with good intent, does not redound to the credit of an institution with such noble traditions as Guy's and which cannot but be regarded as a reflection on a body of medical men who are no less willing to adapt their fees to suit the less fortunate of their fellow creatures than their medical or surgical colleagues." Dr. Lewis Jones contributes a valuable paper on Interrupted Currents in Medical Work. The characteristics of the currents given by induction coils and commutators under varying conditions are illustrated by means of tracings obtained with a Duddell's oscillograph. These tracings, taken with certain observed effects of the various currents on the tissues, have given knowledge not attainable by any other means. It would appear from this paper that the induction coil will for some purposes be displaced by a constant current interrupted and reversed by a commutator driven by mechanical means. The paper should be studied by those interested in medical electricity. Dr. W. Ironside Bruce contributes the notes of a fatal case of cerebral hæmorrhage occurring while under electrical treatment. The technique of Sabouraud and Noiré in the treatment of tinea tonsurans by the x rays is given as an abstract from *Annales d'Electrobiologie et de Radiologie.* There is also an interesting digest of American electro-medical literature by the American editor. The number concludes with an account of the proceedings of the British Electro-therapeutic Society's meeting in April, giving the discussion on the paper by Dr. Lewis Jones already referred to and also a paper by Dr. W. F. Somerville on High Frequency in Insomnia.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

OPHTHALMIC CAPSULES.

(DUNCAN, FLOCKHART, AND CO., EDINBURGH; AND 143, FARRINGDON-ROAD, LONDON, E.C.)

THESE capsules are made of fine gelatin and are pear-shaped. Their long tapering neck distinguishes them from the ordinary capsules used in medicine. On account of the soft nature of the gelatin the capsule may be used directly for administering an ointment to the eye without risk of injuring it. In order to release the ointment it is only necessary to cut off the extreme end of the long neck with scissors and to press the capsule gently. Ointments are prepared having for their base a neutral white paraffin jelly containing atropine, cocaine, or the yellow oxide of mercury. Any other suitable ophthalmic formula may be made up.

"ARTOX" WHOLEMEAL FLOUR AND BREAD.

(APPLEYARDS, LIMITED, ICKLES AND MASBRO' MILLS, ROTHERHAM.)

By a careful process of manufacture "artox" wholemeal flour has been specially adapted for dietetic requirements. As is well known, one of the objections to wholemeal wheat flour is the presence in it of more or less coarse particles of bran which are apt to irritate the intestinal canal. On this account it is probable that though wholemeal flour contains a greater proportion of nourishing constituents than does ordinary white flour, yet this additional proportion of nourishing constituents is not completely available owing to the action of the coarse branny particles in hurrying the partially digested mass out of the bowel. According to microscopical examination the fibrous particles in "artox" wholemeal flour are very finely divided, so that the otherwise irritating properties of the wholemeal is reduced to a minimum and at the same time certain valuable food constituents are released from the cuticle. The chemical composition of "artox" flour indicates a nutritive value superior to that of ordinary white flour since the former contains the entire constituents of the wheat berry. Our analysis gave the following results: moisture, 13·10 per cent.; mineral matter, 1·10 per cent.; proteid, 13·05 per cent.; fat, 2·60 per cent.; fibre, 2·90 per cent.; and starch, 67·25 per cent. A really excellent bread may be prepared from the flour and it has the peculiar attractive flavour and texture of a loaf made from the entire constituents of wheat. A sample of the bread gave the following results on analysis: moisture, 46·09 per cent.; mineral matter, 1·37 per cent.; proteid, 7·56 per cent.; fat, 1·40 per cent.; fibre, 1·50 per cent.; and starch, 42·08 per cent. Here again analysis shows a maximum proportion of the food constituents of wheat. The bread has the advantage also of keeping its moistness and its "nutty" flavour for a comparatively long time. It is a pity that the tendency of modern milling methods is to deprive flour of part of its nutritive as well as appetising qualities. There can be no reproach of this kind in the case of "artox" flour and bread.

THERAPEUTIC YEAST.

(AGENCY: COOPER AND CO., 80, GLOUCESTER-ROAD, LONDON, S.W.)

Beer yeast has long been employed in therapeutics but hitherto in a more or less unscientific way, and it is desirable that, in medicine at any rate, a pure culture should be employed. Moreover, under the conditions in which ordinary beer yeast is produced it is doubtful whether it would continue to serve as an active agent; in the stomach, for example, an acid fluid is encountered and there is a relatively high temperature, both of which are calculated to operate against the energies of the ferment. Recently a grape ferment has been employed for the purpose which is grown in grape sugar solution at a temperature of from 95° to 100° F. It is argued that in this case the ferment is educated to both an acid and a warm environment, so that it will live in the gastric organ, where it is assumed that it elaborates a substance which is antagonistic to the germs, for example, of furunculosis. It is even stated that the administration of an active culture of grape ferment has been of benefit in diabetes. It has also been used in general disorders of nutrition. We have examined the liquid supplied for the growth of the ferment and that containing the ferment itself. The ferment appears to consist of saccharomyces ellipsoidens. On adding the ferment to the grape juice a brisk fermentation ensues in a few days and the yeast multiplies rapidly. At this stage the fermenting fluid is given to the patient. The method of treatment is reported upon very favourably on the continent, and especially in France, and partly on this account and partly because it presents a means of exhibiting a pure ferment in an active condition a trial seems to be called for in this country.

ROBB'S MILK FOOD.

(A. ROBB AND CO., 79, ST. MARTIN'S-LANE, LONDON, W.C.)

Whilst admitting the dietetic merits of the soluble milk foods of this firm in an analytical notice in THE LANCET of Feb. 11th, 1905, we suggested that in the case of food No. 2 the proportion of carbohydrates might be reduced with advantage and that of the fat and the proteid correspondingly increased. According to the analysis of a further sample we have received this has been done, for the proteid now amounts to 15·87 per cent. instead of 7·60 per cent. and the fat to 12·80 per cent. instead of 4·80 per cent. We regard this as an earnest endeavour on the manufacturer's part to make this preparation conform to the particular physiological requirements of an infant's food.

GARCON COFFEE.

(W. FORSTER AND SON, 9, PHILPOT-LANE, LONDON, E.C.)

We have carefully examined this coffee and the results are in perfect accordance with the statement that the coffee is pure and contains no chicory. In our experiments we obtained from it 0·84 per cent. of caffeine, while the soluble extract amounted to 27·04 per cent. It is rarely, in this country at any rate, that coffee is found which yields such a strong and agreeable aromatic infusion as does this sample. The reason for this is that it has been roasted by the French method—that is to say, a small quantity of sugar is thrown into the roasting cylinder just before the process is finished. This small addition is quite harmless and improves the coffee both in regard to its aromatic quality and its intensity of colour. After trying coffee roasted in this way few people, we imagine, would resort to the use of chicory which thickens, it is true, the infusion but spoils its flavour.

HANSEN'S JUNKET TABLETS.

(MR. C. G. SORENSEN: 77, ST. THOMAS'S-STREET, LONDON BRIDGE, S.E.)

We placed these tablets under practical test and were able to prepare a very satisfactory junket. Emanating as these preparations do from the Hansen laboratory at Copenhagen, Denmark, in which so much excellent work has been done on the cultivation of yeast and enzymes, such a result might have been anticipated.

(1) SWEDISH FISH BALLS; AND (2) BATH AND HOME AMMONIA.

(THE CROWN AND LILY GUARANTEE CO., 85, GRACECHURCH-STREET, LONDON, E.C.)

1. The fish balls so adroitly and appetisingly prepared in Sweden are well known by those who have visited that country. We have received a sample of tinned specimens and it is stated that the preserving process is conducted under scientific and hygienic supervision. This we can quite believe, for the fish balls were in an excellent state of preservation, there were no signs of corrosion of the tin, and there was no evidence of metallic contamination having taken place. As a matter of fact, the contents were slightly alkaline in reaction which would account for the surface of the tin keeping bright and clean. The balls are composed of fish and bread and have a good flavour when suitably prepared. 2. The above agency has also submitted to us a sample of fluid ammonia intended for home use. We have no novelty to remark in regard to this preparation but we may call attention to the fact that ammonia is a poison and therefore some precautions in regard to its handling should be printed on the label of the bottle. On the present label we can find no such warning.

SKIPPER SARDINES.

(ANGUS WATSON AND CO., 30, CLOTH MARKET, NEWCASTLE-UPON-TYNE.)

These sardines are stated to be caught, cured, and packed in Norway and they are certainly very good. The fishes are evidently packed in genuine olive oil; they are quite small in size. The flavour is delicately "smoky" and decidedly appetising.

MANHU DIABETIC FOODS.

(THE MANHU FOOD CO., LIMITED, LIVERPOOL, AND 23, MOUNT PLEASANT, GRAY'S INN-ROAD, W.C.)

The question as to whether carbohydrates may be added with safety to the diet of the diabetic patient depends so much upon individual response that it does not seem possible to generalise in this matter. In the Goulstonian lectures recently delivered before the Royal College of Physicians of London Dr. W. Cecil Bosanquet stated that "nothing seems more certain with regard to the treatment of diabetes than that each patient must be a law to himself and that no general rule can be laid down for guidance. In some cases more than in others less carbohydrate food can be tolerated." Of the Manhu Diabetic Foods it is said that the carbohydrates are so modified in the process of preparation that they are easily digested and easily assimilated and in fact yield their oxidation products without aggravating the disease. The proportion of carbohydrate is, however, according to our analysis, the same as that contained in wheat flour but owing to a special mode of treatment the cells yield more readily to the action of diastase and of acids. All that can be said therefore is that the starch has been made more easy of digestion. The foods comprise, besides flour, diabetic biscuits, diabetic macaroni, and some preparations of barley.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XVI [1]

THE PRESENT STATE OF MEDICAL EDUCATION (*Continued*)

The Multiplicity of Examinations —Mr. T Pridgin Teale s Views —Professor F Y. Edgeworth on Chance in Examinations —Sir William Stokes s Views —The Faults of the Examination System.—Centralisation or Decentralisation —The Lightening of the Curriculum

THE medical education of the London student has been treated separately at some length because his circumstances are not only so peculiar but also so gravely important to the community That the clinical material supplied by the metropolis should be properly utilised is of national, and more than national, importance, and that the teaching of London, possessing such material, should not be recognised by students as among the best teaching of the world is lamentable But there is reason to hope that the London schools have "touched bottom" and that we may soon see them restored to their former proud position and aiding as they should in the educational developments that are imminent in the near future For the medical curriculum, as it at present exists, does not defy criticism, it does not even escape reprobation, even though it be to all intents and purposes uniformly arranged at the different centres and be watched over with undeniable vigilance by the General Medical Council The Council itself has now become restless in respect of its educational duties, for it has become manifest that the demands made upon the students at their examinations are *seriously interfering* with their clinical studies As we have seen, the fifth year of the student s curriculum was designed to be devoted entirely to the study of hospital practice Bookwork of all sorts, whether general (mainly preliminary) like the literature of physics, or special (mainly professional) like that of anatomy and physiology, was to be put behind the student's back This was the project of the General Medical Council when the [illegible] had not time in a four years' curriculum to make himself acquainted with all the bookwork imposed upon him by the range of his subjects if he was to give proper attention to the clinical and practical side of his training—that is to say, the side of his training which, as far as the public goes is the only one that counts All his hours were spent in grounding himself for the reception of professional learning, hardly any time was left for the actual *acquisition of* that learning, and none for its practical application Therefore the extra year of study was given him, or imposed upon him, to be devoted to clinical work But the extension of the curriculum has not answered the expected purpose Indeed in the opinion of many people—and not the least observant among those who have studied the subject—the veritable position has again been arrived at to meet which the five years' curriculum was devised

At the session of the General Medical Council last winter this was so far admitted that when a motion was debated with regard to the arrangement of the student s work the speeches of the members showed a general belief that some modification of existing arrangements is wanted It was made clear that owing to the increased demands made upon medical students in the earlier part of the curriculum many of them do not pass their examinations in the preliminary subjects—physics, chemistry, and biology—until after they have made a beginning of the professional section of the curriculum This precludes the undivided attention which the study of such subjects as anatomy and physiology requires, while the fifth year of the curriculum becomes overloaded, bookwork intruding upon the practical routine Some authorities think that the passing of the preliminary scientific examination should be made compulsory before the admission of students to the study of anatomy and physiology, others that the student before presenting himself for his final examination should show that he has devoted at least one year to clinical work alone A third way out of the difficulty would be to increase the curriculum by one more year and this, it may be said would be an increase in name only, for the average duration of time taken by the medical student to get his entry on the Medical Register happens to be six years and one month Against increasing the length of the curriculum there is so much to be said from the economical point that it hardly needs the saying [2] The medical profession is now a very difficult one to enter and if the curriculum were increased to six years duration the education of the student for his difficult career would cost at least £1000, while the majority of medical men would be 25 years old upon becoming qualified Undoubtedly few men earn much money in practice before that time, but as the six years' curriculum would probably lead to a multiplication of examinations and a further increase in the average period of studentship above the statutory period, the General Medical Council, whatever it may feel obliged to say in debate, out of a consensus of feeling that the student must progress with the times, will probably not sanction, at any rate for some time, any extension

The multiplication of examinations is particularly to be dreaded and this is already being foreshadowed There *are a certain number of educational authorities* who would have the student's time so divided off that at the end of each year he is examined in some one series of subjects This puts a premium on bookwork and on the employment of "coaches," and leaves the student to consider the time wasted which is spent in the out patient department and the wards of a hospital Ten years ago Mr T Pridgin Teale, who was at that time one of the Crown representatives upon the General Medical Council, called pointed attention to the danger of over-examination, and his words certainly seem now to be coming true He suggested that the time had arrived when the General Medical Council should consider how far it could reduce the examinations of medical students in number and limit the schedule of subjects Mr Teale showed that during the 20 years that he had sat upon the General Medical Council the examinations had steadily increased in numbers, while he quoted manifold evidence to prove that the element of chance played too large a part in these tests, telling disastrously on some of the best, because some of the most finely organised, candidates He based his conclusions upon statistics of various examinations as actually reported to the Council by Mr J C Miller the late registrar of the Council Mr Miller s figures showed that the percentage of rejections in examinations among medical students amounted to 37 1 in the primary, 47 1 in the intermediary, and 38 9 in the final In 1876 the percentage of rejections in the final examinations only amounted to 22, the figures showing that the more examinations are multiplied the more fatal they become This is certainly a poor result of education and would tend to show either that a good deal of the teaching received by the medical student is not much to the point or that the element of chance that must always exist in any examination, becomes unfairly aggravated when every student has to pass a complicated series of examinations For education and examination are not interchangeable terms, the examination is the test of the education, and if nearly half the students fail in an examination the education is demonstrably at fa[illegible] cannot be attributed to [illegible] ie influence of chance in [illegible]

One of the best things ever said about examinations in illustration of their value and their limitations occurs in a paper read by Professor Edgeworth, Professor of Political Economy at Oxford before the Royal Statistical Society [3] Here test examinations are compared to "the barometer an instrument which directly measures the pressure of the atmosphere, but only inferentially, and as one sign among others, indicates that about which it is mostly consulted the weather The successful negotiation of an examination proves a student to have acquired some temporary knowledge and to possess some ability for exposing that knowledge, it is only one sign among many that he has been well educated or has any real efficiency. But a well constructed barometer is a better weather guide than a bad one, and in the same way a capricious examination is less a test of permanent worth than an examination where the element of chance plays no part. There is no such rigidly perfect examination, and the question of how far the workings of chance play a part in the results of examinations must always be considered. Professor Edgeworth appraises the possibility that an error of assigned extent will be committed by a competent examiner in marking a piece of work of any given sort in a most instructive and ingenious manner. Assuming that the mean of a great number of judgments constitutes a true standard of taste—and the marking of an examiner must be a matter of taste—he shows that the same hesitation which the conscientious examiner must have in assigning marks comes over the man who is asked to estimate simple objective quantities, such as the height of an acquaintance or the number of five pound notes which will balance a sovereign. And just as by observing the estimates made by a number of persons as to the weight or height of the same body the law of error can be discovered proper to similar species of estimates, so by observing the marks given by a number of competent examiners to the same piece of work an empirical law can be ascertained the working of which may be extended to similar cases. He records a number of experiments in the marking of mathematical, classical, and historical papers and shows that there are plenty of data upon which to found assumptions as to the part played by chance in the results. Referring to examinations for the Indian Civil Service, the Home Civil Service, and the Army he finds the element of chance to be such that in any given examination the chances of displacement upon re-examination would amount to one-seventh. Judging by this figure it is clear that we must not look to chance to account for the grave number of rejections in medical examinations, but rather to the errors of the system of training, and sometimes undoubtedly to the faults of the examiners. A rejected candidate often thinks that his examiners are very silly fellows, and is often mistaken, but a study of the questions that have on some occasions been asked by examiners leads to the view that medical students have here now and again had a genuine grievance. What is the use of asking medical students in their early examinations elaborate questions as to the comparative action of drugs when they have never seen a sick man? And what is the use of asking men in a pass examination in surgery for descriptions of rare and elaborate operations? The fact that the candidates can describe, and presumably perform, all the operations that they might be called upon to carry out *in any emergency* must be elicited, but it is unnecessary to expect more of a man who has had no experience. Naturally, when in practice some grave procedure lies before him, where immediate action is not the only chance of success, he will revise his knowledge and will try to supplement it before operating; why, then, should he be rejected in an examination for not having this class of surgery at his fingers' ends?

[3] Journal of the Royal Statistical Society, 1890, vol liii.

In England, Scotland, and Ireland alike the same feeling of dissatisfaction at the examination system as applied to medical education has at different times prevailed and has found voice among some of the best known teachers, among whom may be mentioned the late Sir George Humphry, Professor Pettigrew, and the late Sir William Stokes. Sir George Humphry, one of the best clinical teachers that England has ever seen, said in a memorandum addressed to the General Medical Council upon the subject of the numerous rejections of candidates for medical examinations: "The burdening of the memory with mere facts which have no direct or obvious connexion with science or practice—with facts, that is, unassociated with ideas of practical utility—is, on the whole, of little value educationally or otherwise, and such facts make but a transient impression on the memory. Laboriously crammed together, with efforts worthy of a better purpose, they are with difficulty held until the examination crisis and then quickly escape with little regret at their departure. Indeed, examination in each subject of professional study should be restricted to the general principles and the more important facts of the science, and should be of such a character as to induce students in their preparation for it to observe and think for themselves more than is now commonly the case. The examinations should be regarded from an educational point of view, with reference, that is, to the influence which they are likely to exert upon the character, the education, and the mental training of the students, as well as with reference to their being a test of fitness for admission to the Medical Register."

Sir William Stokes, in opening the medical session at Meath Hospital in the same year that Mr. Teale made his remarkable appeal to the General Medical Council that they should guard against an abuse of examinations, gave as follows the result of his long experience as a teacher and as an examiner: "The student, wearied and weighed down by an accumulation of courses and with the sword of Damocles in the shape of an annual examination ever hanging over his head, has neither time nor inclination to do anything that, in student parlance, will not 'pay' in the examination. It seems to me that the outcome of most modern changes in the medical education is in the direction of making students read, not few books well, but many books badly, and that the brain has been looked upon too much as an organ with an unlimited capacity for retaining, digesting, and absorbing in a given time every ascertained fact, not only of medicine and surgery, but also of all the sciences auxiliary to medicine. The attempt to carry out the arrangement is fraught with real injury to many, with disaster to some."

The gist of the words of these authorities was the same. They found that the extension of the medical curriculum in 1890 had by 1895 failed in its object. The extra year had been designed to be used for clinical work in the hospitals, the student, presumably clear of bookwork, learning the practice of his profession—either "walking the hospitals," to use the old-fashioned phrase, or gaining experience otherwise in practice. So much was this the intention that the Council had sanctioned a term of pupilage at the end of the curriculum to count as part of the five years and in a measure to take the place of the old system of apprenticeship. As a matter of fact, the fifth year is almost always spent by the student with his nose in his books. Everyone sees it now and five years ago it had become clear to observant teachers. The student cannot afford the time to do clinical work or to record impressions and experiences in the ward when there is so much bookwork to be got through. The position forms a strong indictment against the habit of multiplying examinations and of splitting the subjects of the curriculum into a number of groups, and a no less strong indictment against the educational methods employed. Too much stress must not be laid upon the fallibility of examiners who in the minds of many are responsible for a part of the failure of the existing system of medical education. At some of the centres of education the examiners are chosen by the General Medical Council with great care and at all the examinations are inspected by the central authority, mainly with the object of seeing that the student obtains fair play. The arrangement by which the questions are selected is at many examination boards an elaborate one, aiming at securing a fair and commonsense test, while the student is always subjected *vivâ voce* to the attention of two examiners simultaneously, that there may be a witness, and possibly a supporter, in case he is rudely handled. Granted, however, that examinations are conducted with as much fairness as possible, the fact still remains that the medical student's career is too much embarrassed by them. He spends time that could be spent in a better way, learning by rote things that he believes will secure a safe passage through his next examination; he spends his parent's money trying again when previous endeavours have been futile; he spends his energies and his spirits, and when he gets through the examination he has swallowed, in the desperate intention of avoiding all possible chances of failure, lumps of information that he cannot digest.

There are two really substantial reasons for examining a medical student, or any other professional student, and these should always be held in view by those who have charge of his education. The first of these is to see that he is sufficiently well acquainted with the subjects of preliminary education to enable him with advantage to pass on to the study of the technical requirements necessary for him to practise the daily work of his profession. The second is, of course, to see that he has learned his work sufficiently well to enable him to practise with benefit to the public. With regard to the first, it is doubtful if the present guarantee in preliminary education in the medical profession is a sufficient one. The standard has been much improved in recent years but it could be raised with advantage. It is at this end that the unfit should be stopped. The student who is bound to extend a five years' professional education into one of seven, or even more, years because his general education has been neglected should be peremptorily barred at the outset instead of being allowed to struggle on, passing his subjects piecemeal, and attacking each stage of his career with all the disabilities attending an imperfect knowledge of what he has put behind him To turn out practical medical men is, or should be, the aim of medical education This result is not achieved by admitting all and every to the professional examinations From such crowding comes hurry, the ever-present element of chance is unduly increased, good men meet with undue disaster, and ineffective work is done by examinee and examiner The remedy for a multiplicity of examinations is to start with a test of proper stringency, one which insures that the persons who would inevitably have fallen somewhere by the wayside should fall at the start, and one which also insures that the man who passes has acquired a grounding that should make future professional tests easier.

Certain subjects are given the medical student to learn and five years are given him in which to learn them theoretically and practically, after passing an entrance examination of varying stiffness He takes on the average over six years to satisfy the examiners of the different qualifying boards that he is up to their standard, and their standard is regulated by the General Medical Council up to a certain point The lengthening of a nominal five years' curriculum into a virtual six years' curriculum cannot be considered satisfactory—all the economical arguments against the statutory retention of the medical student in the pupillary state for six years can be employed with double force against a condition of things which retains him there by providing him with no proper chances of getting through his work in the allotted spell But the direction in which to look for a remedy is not so clear as is the necessity of looking To lower the standard of medical knowledge at a time when all around the standard of other professional knowledge is being raised would be quite unthinkable To multiply examinations so that the student can take his subjects in many small parts and put them behind him bit by bit is a vicious plan—the percentage of failures is

their own students in the ancillary sciences "We must decentralise," he said, in the address from which I have already quoted, "we must unload our public examinations We must relegate to the schools not only to teach but to examine and to certify in all secondary subjects, such as elementary biology, materia medica, pharmacy, hygiene, perhaps even chemistry, and certainly forensic medicine Then let *all the rest* be covered by three public examinations—one in anatomy and physiology, presumably at the end of the second year of professional study, one in pathology and therapeutics at the end of the fourth year, and the clinical examination in medicine and surgery,
n in midwifery (truly in
logy), at the end of the fifth
be able to afford to examine
more thoroughly and less hurriedly, to find out what a student really knows, and to re examine those on the border line of pluck or pass Then, when plucking examinations are reduced from nine to three and become less matters of chance, there will be some room for calm clinical study, for self training, for learning something during studentship of that very important and terribly neglected better half of the training of a true medical man, the knowledge and observation of the human being "

Mr Teale's indictment of over examination was thoroughly sound and justified by facts, but his remedy is not convincing To permit the different medical schools to examine and pass their students in the preliminary subjects would be to court incalculable trouble, for the stress of circumstances might at any time lead to a down grade competition between the schools The General Medical Council could never resign to all the medical schools between Belfast and London, between Aberdeen and Bristol, so much of its discretion and authority as would be implied by allowing the schools to examine their own students in half the subjects of a medical curriculum Centralisation rather than decentralisation is the remedy

First, it is necessary to secure a sound preliminary education for the medical student, as a certain percentage of rejections certainly come from the fact that a large number of candidates have not been taught how to learn. Here the General Medical Council might well insist upon more stringent tests than are yet employed, while it is greatly to be hoped that all the lads in the kingdom intending to enter a profession will soon be submitted to one form of test before entering upon their special studies As has been recently pointed out in the columns of THE LANCET,[4] it is a fact familiar to all who have entered professions and more painfully, perhaps, to those who have desired to place sons in them, that there is a multiplicity of examinations which qualify for entrance Many bodies hold examinations of this kind which, although identical in standard, are yet altogether diverse in the details of their requirements The effects of this diversity are serious not only to schools by rendering it impossible for boys working for the different examinations to be taught together but also to the education of the boys preparing for the examinations by depriving them of the regular class instruction during their preparation It would therefore be a great gain if there were a recognised standard examination the exact requirements for which could be taught in schools all over the country and the successful passing of which would qualify a boy in the eyes of such bodies as the General Medical Council, the Institution of Civil Engineers, and so on, to enter upon the particular studies required by the examining bodies for the different professions The Board of Education, through a consultative committee, has recently proposed to inaugurate such a scheme and in doing so has been assisted in its efforts by the General Medical Council The consultative committee of the Board of Education considers that the general system of school certificates which is desirable should be granted upon examinations controlled "by a university, by a combination of universities, or by an examining board representative of a university or universities and of the local bodies prepared to cooperate with them" The more generally representative this authority is made the better will it serve the purpose of the medical profession If practically all medical students enter upon their special studies after passing the same preliminary examination, and that one of proper stringency, the teaching in classes corresponding to years of entry would be much easier, and the percentage of rejections would fall at once considerably The examination of medical men by the State for a State licence to practise is not a revolution that is outside the range of practical politics, but such a reform—for reform I hold that it would be even now, though all the circumstances are altered since THE LANCET first started a powerful movement in this direction—will take time to accomplish

Centralisation of medical education as far as the provision of an adequate entrance examination for all candidates would be a thoroughly useful reform Centralisation again as implied for common classes of instruction for London medical students is very desirable But when centralisation comes to be taken as far as the institution of a State examination for a State licence to practise, opinion is not so solid in its favour For the pressing trouble some immediate relief should be found and it will consist in lightening the curriculum wherever possible without lowering the professional standard If the curriculum cannot be lengthened upon economical grounds, if the standard cannot be lowered for equally cogent reasons, and if a multiplicity of examinations appears to mean simply an increased percentage of failures, but one course is left open The curriculum must be weeded Without in the least lowering the standard of knowledge demanded of the student upon essential points and without relaxing any effort to make his knowledge of the more important subjects sound all that is not absolutely necessary in the secondary subjects should be excised from the schedule The amount of botany demanded of the student might be decreased and schedules should limit the study of chemistry and biology in certain directions so that teaching could be employed directly upon the lines indicated Outside these lines examiners should be instructed to attribute the greatest importance to practical work. In this way, given a sensible preliminary examination all students of good capacity should be able to obtain their qualifications in five years, and students not so favourably dowered had better try another walk of life.

(To be continued.)

[4] THE LANCET, Dec 10th, 1904, p 1666.

THE LANCET.

LONDON: SATURDAY, JUNE 17, 1905.

The Metropolitan Hospital Sunday Fund.

This is the one occasion in the whole year when we address the public directly and every year, when we do so, we say the same thing—that the Metropolitan Hospital Sunday Fund and its sister institution, King Edward's Hospital Fund for London, are, of all the charities which have ever been devised, the most fitting for general public support. They have the greatest right to expect an enthusiastic backing from those who understand their objects, and they appeal alike to the rich and the poor, to the virtuous and the frail, to the sick and the sound. Nor is there any difficulty in understanding the aim of these funds; they desire to introduce order into charity, to support those noble institutions, the London hospitals, in an openhanded but economical manner by dowering what is best in them and by assisting them to deal in a well-regulated fashion with the awkward problems of hospital administration.

We find typified in these funds the working of charity combined with organisation, two things which—despite the excellent record of the society which is inevitably called to mind by the conjunction of the words—most would think to be in complete antagonism to each other. Charity, the charity of the Epistle signifies love and cannot, many will be found to say, be confined by rules. Love knows nothing of rules, and it cannot be truly charitable to give so much money to one cause and so much to another, and to have reasons for not giving so much more money to yet a third. Generosity of spirit goes on to suggest that it is not truly charitable to wonder whether the object of our ministrations is a worthy object. It may be that unworthiness constitutes the most essential part of the claim upon our purse and our attention. It is just because the hospitals of London are administered in this spirit that no one need ever hesitate about subscribing to their support, and the Metropolitan Hospital Sunday Fund, the subject of these reflections, true to the religious tone which underlies it and pervades it, desires no regulations whatever tending to confine the benefits of the hospitals to so-called deserving persons. The order that it desires to introduce into charity implies merely the business principles of administration, and this because the good work of the hospitals can be enormously increased if the available funds are spent in a proper manner—in a manner conformable with the theory that a hospital is a charitable institution for the relief of the sick and injured poor and is not a rate-supported infirmary or a centre for the *cliniques* of distinguished medical men, or a convalescent home. Regarding the matter in this way we see that a certain amount of order in charity is necessary or the uses of the charity may be curtailed, though the necessity may be due to the imperfection of this world—a world of compromises where continually the best has to be done in unpromising circumstances and by imperfect methods. There is not a system of religion which has been devised which does not find war wicked and stupid, but, on the other hand, there is not a system of government which has been devised that does not find recourse to arms in behalf of the right a necessity. In the same way if this were Utopia no order in charity would be required because the supply of charity would exceed the demand and the struggle would be not to obtain support for this or that good object but to be the first to subscribe to this or that good object. When this position is achieved, when the supply of practical charity equals the demand, the necessity for economy will be gone, but until that day arrives it seems to us that every effort will have to be made by practical lovers of their fellow-men not only to raise funds for charity but to husband them, so that they may be employed only to the best advantage and only in behalf of those for whom they were intended.

At the present time all civilised nations have upon their hands a number of poor, of used-up, of incompetent, and of criminal persons, for whom assistance has to be found in sickness and in health, and especially in sickness. In their behalf charity should always be active but for their relief only inadequate means can as yet be found. Selection must therefore be made among the many claimants for our charity, and the moment the principle of selection is put into play the person who is poor and sick at the same time is seen to be by far the most urgent candidate for protection. Timely ministry to his physical needs may restore him to society as a useful and valuable citizen. His plight is in most cases due to no fault of his own, while his sufferings are accentuated by the fact that only too often all his family have to suffer with him; and not to suffer in their feelings only. The sick parent may mean the hungry child and the ruined home, unless the breadwinner can be promptly restored to health. There is little need to elaborate the points that have been thus briefly set down and which will serve, like the Rev. C. H. Grundy's practical little homily, which we publish in another column, to elaborate the message of our usual Hospital Sunday Fund Supplement. That Supplement will be in the hands of a large section of the public by next Sunday and it is our earnest hope that it may arouse in some of them the desire to make the Fund a success. Through Mr. George Herring's noble generosity every pound given to the Fund automatically becomes 25*s.*, while his decision to rank the City of London as a place of worship within the meaning of his benevolent act increases the liability upon him. We trust that we may have in subsequent issues of The Lancet to chronicle a splendid list of subscriptions, and that the total may this year attain to the coveted figure of £100,000, the sum which imagination, for no very good reason, appears to fix as the maximum to which it can attain.

Vicarious Excretion.

ONE of the most remarkable facts in connexion with the physiology of the animal body is the power by which the function of one organ can be performed by another. In the lowest organisms this power is most marked. The hydra consists for the most part of two layers of cells, the superficial layer serving as a cutaneous envelope while the deeper layer incloses the primitive alimentary canal and performs digestive functions. By the use of extreme care it is possible to turn the hydra *inside out*, so that the lower formerly digestive inner layer now is superficial and serves to protect the animal, while the former cutaneous layer surrounds the new digestive cavity and, what is more, it secretes a digestive liquid which, acting on the food, suffices for the nourishment of the hydra. Such exchange of functions is not very surprising in so low a creature, for the cells in the hydra are not very far removed from the unicellular amœba, where the same mass of protoplasm can undertake in turn, or even simultaneously, the most varied functions. As we ascend the animal scale the actions of cells become more differentiated and with the increase of differentiation there is diminution of the power of undertaking many functions in turn. The cells become specialised and have to sacrifice a number of their powers in order to attain to greater perfection in the remainder. Yet even in the higher animals we find evidence that the same function can be exercised by more than one organ. A dog from which the spleen has been removed may be as healthy and as normal as a dog provided with a spleen, and though we may not be fully acquainted with the functions of this organ yet from the well-being of the animal after splenectomy we may be assured that the functions of the spleen are being exercised by some other organ or organs. In some cases it is possible that there have been accessory spleens (lienculi) which have hypertrophied and thus replaced the organ which had been removed; but this explanation will not suffice for all cases, for necropsies have in some instances shown that there have been none of these accessory spleens present.

Exactly the same observations have been made on human beings. Many times the spleen has been successfully removed, especially after injury, and yet by no symptom could it have been diagnosed that the spleen was not there. The functions of the spleen have been undertaken by some other tissues or organs. When one kidney has been removed the other undergoes a true vicarious hypertrophy, growing obviously larger and becoming capable of fulfilling completely the duties of its lost fellow, in addition to its own. These well-known facts perhaps prompted Mr. F. ROWLAND HUMPHREYS in the choice of the subject of his oration at the annual meeting of the Hunterian Society. For he discoursed in an interesting address on the Vicarious Excretion in Bright's Disease. The excretory function of the kidney is of the first importance and Mr. HUMPHREYS'S paper was in the main an examination of the question as to how far other organs are capable of undertaking the functions of the kidney when it is diseased. The skin and the bowel are the organs which can endeavour to replace the kidney but the extent to which the skin does so is much exaggerated in common opinion. In health the skin does excrete some urea and other nitrogenous products; it is true that the quantity is small but in health the skin does not appear to replace the kidney at all, for, according to LEUBE, the nitrogen of the sweat is greatest in amount when it is greatest in the urine. In disease, however, it has been found that with small urinary excretion of urea the skin may excrete a greatly increased amount; in some cases it would appear that the epithelial cells are capable of allowing the passage of nitrogenous matter by dialysis *in proportion to their loss of vitality.*

Mr. HUMPHREYS suggests that it might be possible to make use of an artificial diminution of vitality in the epithelium to increase its dialysing powers. The bowel has only recently received full recognition as an excreting agent of nitrogenous matters, for KRUGER and SCHITTENHELM have shown that even in health four times as much of those substances classed as purin bodies pass out by the bowel as are excreted by the kidneys. It is also true of many other substances that excretion by the bowel is by no means negligible and in disease the value of the intestinal excretion may be greater still. Mr. HUMPHREYS points out that if sodium and magnesium salts are administered in Bright's disease in order to carry off some of the accumulated toxins a large amount of the salts passes into the blood and this will induce by osmosis the passage of a large amount of tissue waste and toxins from the tissues, and as the kidneys are incapable of dealing with even the normal quantity of such substances they will set up a toxic condition. The subject of vicarious excretion, whether considered only in connexion with Bright's disease or not, is extremely complex; the chemical and physiological problems are far more elaborate than used to be thought and our increasing knowledge has hitherto only served to show how little we know. We know that the vicarious action of the skin and the bowel in renal disease is of vast importance and really that is about all that we do know. But astute theoretical and pathological surmises are all the more welcome because at present an exact knowledge is small. The practical chemist and the observant *clinician can keep* the theorist from obtaining a hearing for theories only, while they are the first to allow that imagination has ever played a great part in the discovery of the truth.

◆

Glanders in London and Elsewhere.

A QUESTION of considerable importance was addressed by Mr. F. A. CHANNING to the President of the Board of Agriculture in the House of Commons on May 31st, in reference to the circumstances disclosed at the recent inquest on a fatal case of acute glanders in man. The case illustrates the danger of the spread of the disease from infected horses to man and the difficulty of diagnosis of the human cases. The deceased was a horsekeeper in the employ of the Andrew Star Omnibus Company at Fulham, in whose stables cases of glanders have occurred from time to time. He complained of pain in the left side and was feverish on May 1st and his condition was regarded as due to pleurisy. Two days later he was sweating profusely and complained of pain in various joints. On admission to St. George's Hospital on May 8th

Association (Dr. W. Collier), and Mr. Plowden, the well-known police magistrate. The toasts of "The Coroners' Society," given by Mr. T. H. Openshaw, C.M.G., F.R.C.S., and responded to by Mr. Butcher in an interesting speech, and "The Officers" were duly pledged, the President eulogising the honorary secretary, Mr. Walter Schröder, for his invaluable assistance to the council and to the many members who wrote to him for his opinion in cases of emergency and difficulty. Mr. G. P. Wyatt and Mr. Schröder replied. The Arcadian glee singers gave a very good musical programme and a most agreeable evening was spent, the company dispersing about 11 P.M.

THE METHODS OF DISTRIBUTION OF ICE.

THE approach of warmer weather calls attention to the unsatisfactory methods under which ice is distributed in this country. The purity of ice has frequently been referred to in THE LANCET. Everyone is familiar with the method of handling huge blocks of ice from an open lorry to, as is usually the case, an underground cellar. A sack, more often than not filthy by constant dragging along the pavement on which it is placed, is used not so much to keep the ice clean as to break the fall. The blocks of ice are lowered down a ladder or board to the sacking. The ice is then pushed along the pavement to its destination, either a shed at the back of the premises or a cellar. This method of handling ice may be seen every day in any large town. Huge quantities of ice are used nowadays, especially by butchers and fishmongers, in hotels and restaurants, and for the preparation of "ices" and iced drinks. Bacterial contamination due to ice is bad enough in the case of meat and fish, though the cooking of these foods probably destroys the micro-organisms. In the case of "ices" and iced drinks, however, any bacteria introduced by impure ice remain unaffected until they reach the mouth and alimentary tract of the consumer where their activity may be aroused. It is therefore of the highest importance that care should be taken not only to obtain ice from pure sources but to maintain it by all possible means in a state of purity. As to the source of ice, there can be no doubt that the purest ice is obtainable from pure water that has been boiled, cooled, and then artificially frozen, but on the whole the natural ice obtained from the Norwegian fields is excellent in quality and any superficial impurity can easily be removed by rinsing. But the use of stout wooden tubs fitted with linings of pure tin and mounted on runners would form a distinct advance on the rude method of its distribution at present in vogue.

THE NECESSITY OF ATTENDING TO AURAL DISCHARGES.

PERSISTENT discharge from the ear has not until comparatively recent years been recognised in its true significance by the profession and it is only amongst the more cultured and intelligent of the laity that any real appreciation of its potential dangers exists. The reasons for this are not hard to find, for although Sir William Wilde, the famous Irish aural surgeon, in 1840 pointed out the dangers accruing from neglected aural discharge, yet unfortunately his words did not make a due impression upon the medical profession. Wilde lamented the fact that it was considered dangerous to check the discharge of otorrhœa as being a fruitful source of trouble but we find that this idea persists even now amongst the public, while until recently many practitioners of medicine failed to see the possible dangers implied in an aural discharge. An aural discharge frequently ceases at the onset of intracranial complications, so that the symptom no longer exists just as the seriousness of the condition becomes manifest. Another circumstance which has rendered the laity blind to the dangers of otorrhœa and slow to seek medical advice is that the patient frequently gets well without treatment. This is the origin of the belief that a child "will grow out of the discharge." The by no means infrequent cases of spontaneous cure have also had another result—quacks have seen in ear diseases a likely malady for cultivation. Quacks, in fact, at all times have reaped a rich harvest from the "treatment" of aural diseases, and in England we have witnessed the immense scale upon which the Drouet Institute, assisted by a complacent press, conducted its operations. Even the Drouet Institute, however, hardly achieved the superlative wickedness of a French aurist who killed a large number of people by filling their ears with plaster of Paris in order to "cure the discharge." We have read that this person "received the deserts" but we cannot believe it—the age is too humanitarian. To return, however, to the undoubted neglect of aural disease by medical men in times gone by, the scanty attention given to the teaching of the subject has been responsible in this country for the disregard of aural discharges. We are awake now in the matter and there is one important fact also which has worked in a very practical way for the due recognition by the lay mind of the latent dangers of otorrhœa. This is the fact that life assurance companies with but few exceptions are now declining lives where this condition exists. The public can appreciate the significance of this and see that it means a simple assertion that a discharge of the ear is a danger to life. Careful and skilled attention is necessary for the treatment of these conditions, but this skill and care are no more beyond the range and abilities of the averagely endowed practitioner than are the necessities of midwifery. Happen what will, a large proportion of cases will require operation, either a minor operation, such as removing the ossicles with the remains of the drum, or the more extensive radical operation. Both these are extremely satisfactory in skilled hands and the former finds its chief use in soon enabling the busy man to resume his labours. But it cannot be too firmly impressed on sufferers from suppurative otitis media or those responsible for the well-being of such persons that a chronic otorrhœa is a constant danger.

DANGEROUS PERFORMANCES.

AT Hastings, on the Saturday before the recent bank holiday, a man named Davidson gave an exhibition at a public recreation ground, consisting in balancing feats of a not unfamiliar character, executed on a rope or cable stretched 40 feet above the ground. In the midst of his performance the pole with the help of which he was maintaining his equilibrium slipped from him and as he failed in an attempt to grasp the rope he fell to the ground and was killed. A large crowd had assembled to see him and some of these, no doubt, went home sobered and saddened by the catastrophe. At the same time, of others of those present it must be said that they were influenced to a large extent by a morbid desire to see a dangerous performance and on this occasion the dangerous element produced a fatal result before their eyes. Tight-rope performances are not particularly attractive in themselves and if Davidson had advertised his feats as about to take place three feet above the ground or as rendered perfectly safe by means of a net he would have been without an audience, although the skill exhibited would have been the same. Some of those who flock to exhibitions such as his may say in their own defence that it is the exhibition of courage displayed by the performer that they go to see but they must be perfectly aware that the performance is to the chief actor in it a work of routine and that he has long ago lost the nervous feeling which affects some of us when we look down from what is known as a "giddy height' Davidson was no more likely to be affected by the fact that he was 40 feet above the ground than an ordinary person is alarmed when he looks out of a second floor window Nor was his loss of the pole in any way due to it The element of danger, however, was necessary in order that he might be able to attract a crowd and so to earn his living and he pursued his calling to its fatal end The *Daily Telegraph* in an interesting note appended to the report of his death reminds us of some of his more famous predecessors in this particular form of exhibition Of these, Mademoiselle Saqui lived to be 80 years old, dying in 1866, and Blondin, who also died in his bed in 1897, was 73 years of age Many others whose names are not chronicled have perished in attempting to attain the skill necessary to become renowned public performers, but our contemporary mentions two women Miss Young, who died a cripple from injuries sustained at a public performance, and the "Female Blondin who was killed on the Aston Park recreation ground at Birmingham in August 1863 It was on this occasion that Her late Majesty Queen Victoria evinced that sympathy with her subjects which always distinguished her, combined with the sterling good sense no less conspicuous in her character for she wrote to the Mayor of Birmingham expressing her horror that one of her subjects, and a woman should have been "sacrificed to the gratification of a demoralising taste in a public playground which she and the Prince Consort had opened in the hope that it might be for "the healthy exercise and rational recreation of the people' As a matter of fact, the ground in question was outside the jurisdiction of the official to whom Her Majesty s letter was addressed and the stopping of a performance of a grown up person on the score of danger is not easy to effect The best safeguard for the performer is in a healthy public opinion when it can be roused, and of performances upon the tight or slack wire it may also be said that they are so dull and monotonous, even with the element of danger, that their season of popularity, at its height in the days of Blondin, has long been over

THE PROPER WAY TO EAT

THE two articles which we published[1] dealing with the manner in which swallowing is effected by the human being touch on a subject of constant interest and importance Dietetics and all that relates thereto form a branch of medical science that appeals to the general mind as perhaps no other branch can hope to do Every man be he gourmand or ascetic, must eat to live and to the one even as much as to the other, there is an interest and an importance about the details of the way in which this feeding process is accomplished that few other natural processes entail to an equal extent Whether because he wishes to get the largest amount of pleasure at a minimum risk of dyspepsia in the case of the gourmand, or because he wishes to get a maximum amount of nutrition with a minimum expenditure of time and energy, as with the ascetic man in either case wishes to know how he eats, what becomes of his food, and why these things are just as they are and not otherwise Mr Hubert Higgins has opened up an interesting side of the question in his discussion of the poltophagic and psomophagic capabilities of mankind He has shown how both anatomically and functionally man can choose at will which method of swallowing he will employ and we believe with Mr Higgins that much would be gained if all could resolve upon and adhere to, the more troublesome but more hygienic method. No medical man doubts that if all his patients took longer over the mastication and insalivation of their food his labours in safeguarding their bodily health would be lightened in a large degree Unfortunately the constant tendency of civilisation and of social arrangements is to minimise the time given to mastication and to insalivation The cook and the conversationalist are allied against mastication The one prepares food that hardly calls for mastication and that offers little or no resistance to the grindings of the teeth, the other employs his art to stimulate movements of the tongue entirely unconcerned with the preparation for deglutition of food A man cannot in polite circles at once talk and eat Whereas dinner time should be devoted to eating we constantly sacrifice the precious moments to speech and risk a dyspepsia rather than fail to let loose a *bon mot* The labours of Mr Horace Fletcher and of Mr F H van Someren may effect a permanent change in our table customs Perhaps we shall see started a "society for the propagation of poltophagy and shall recognise its adherents when we see a silent but healthy looking dinner party of quietly chewing folk We do not maintain that the more spiritual side of conviviality will be enhanced but there can be no question of the desirability of chewing or poltophagy from a purely physical and gastronomic aspect

VACCINATION THE DURATION OF IMMUNITY

AT the meeting of the Société Médicale des Hopitaux of Paris on May 5th M Sevestre brought forward some evidence showing that the duration of the immunity after vaccination is shorter than is generally supposed A child, aged three years was admitted to the measles pavilion of the Bretonneau Hospital with an eruption which was supposed to be of that disease but which turned out to be a prodromal rash of variola All the patients in the pavilion, who numbered 27 were immediately vaccinated Three left two days later before the result of the vaccination could be ascertained Of the 24 others two, aged 11 and 13 years, showed two and three well developed vaccination vesicles respectively The former child had no vaccination scar and the latter had been unsuccessfully vaccinated in infancy In addition well-developed vesicles were obtained in two children who had well marked vaccination scars and whose ages were two and four years respectively The child who suffered from variola was only three years old and showed one vaccination cicatrix Thus out of the 25 children one who showed a vaccination scar, was attacked with variola at the age of three years and in two others aged two and four years respectively, vaccination was successfully performed in spite of the existence of well marked vaccination scars M Sevestre, therefore, concludes that in the case of an epidemic of variola or of exposure to infection from a sporadic case children should be vaccinated, even though only a few years old and showing well marked vaccination scars In the discussion that followed cases were mentioned in which recruits were successfully vaccinated although the same result had been achieved a short time before M Roger stated that he had successfully vaccinated in 1897 six children at ages varying from 16 months to five years who bore the scars sometimes multiple of primary vaccination M Joseph Belin mentioned the case of a woman who was successfully vaccinated in infancy and had confluent variola in 1868 at the age of 28 years In 1870 she had discrete variola From 1871 to 1881 Professor Brouardel vaccinated her every year successfully The allied but distinct question of the duration of the protection against variola conferred by vaccination does not seem to have engaged the attention of the society We may point out that the Registrar General s statistics of the small pox epidemic in London in 1901 02 showed that vaccination affords complete protection against death from small-pox for ten years. But all practitioners will agree as to the wisdom of the advice to revaccinate even young children who have been successfully vaccinated if they are exposed to the infection of variola. Exceptional cases occur and it is by representing them as the rule that a large part of the antivaccinationist propaganda is carried on. It is noteworthy that the child referred to above who had variola showed only one vaccination scar and therefore was imperfectly vaccinated.

---

[1] THE LANCET May 20th (p 1334) and 27th (p 1417) 1905.

THE NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM.

A MEETING of the Neurological Society of the United Kingdom will be held at the National Hospital for the Paralysed and Epileptic, Queen-square, London, W.C., on Saturday, June 24th, at 10 A.M. The morning will be devoted to the exhibition and the discussion of clinical cases and the afternoon to pathological demonstrations. Lunch will be provided for all members of the Neurological Society at the Hotel Russell. In the evening the metropolitan members will entertain the extra-metropolitan members at dinner at the Imperial Restaurant, Regent-street, at 7.45.

A PLEA FOR THE SUPPLY OF NATURAL MILK.

WE should be wrong probably in saying that there was not a pint of milk sold in London exactly as it comes from the cow, but we should not be far out if we said that at least, and probably more than, nine-tenths of the supply is not in its perfectly pure, natural condition. When it is not watered it is deprived of part of its fat or preserved with a chemical substance. The law provides a remedy against these forms of tampering and offenders are frequently brought to book, but no attempt appears to be made to check the enormously increasing practice of adding a dye to milk to make it look rich and creamy. Surely the phrase "to make it look rich and creamy" implies deceit and fraud. At all events, no milk can be called natural that contains an added dye. The fact is that the eye is trusted too much by the public nowadays as a guide to quality and the unscrupulous tradesman is not slow to take advantage of the adoption of this frequently false criterion. It is the same story in regard to the white loaf; as white is an emblem of purity itself it must follow that the whiter the loaf the purer must the bread be. From one point of view that may be true but only when the essential nutritious and appetising constituents are regarded as impurities. With milk the case is reversed; it must not be white but a creamy yellow or brown. The addition of annatto or of methyl-orange to milk does not augment, it is needless to state, its creamy constituents. They remain just the same but the colour is heightened in order to create the impression that more cream is present than is really the case. Surely the intention here is to deceive, to convey a false impression to the consumer that the milk is rich. The public would be far wiser if it would entertain always a strong suspicion about milk which presents a decided brown coffee-like colour. The milkseller in his anxiety to impress the public with the excellent "creamy" quality of the milk which he supplies invariably overdoes the trick and the result is a milk having a colour more like that of pure cream than that of milk. But it is possible to find pure cream and pure milk which are nearly white. After all it is only the cream of certain breeds of cows that is decidedly brownish in colour. Brown is no more normal to cream than it is to a new-laid egg. There are many people by the way who choose the brown-coloured egg in preference to the white one because the former looks "richer." Here again this preference is met by staining the white egg a coffee colour. It is time that this tampering with the normal appearance of milk by adding dye to it should be stopped. The practice is very extensively pursued judging from several samples of milk which we have recently had occasion to examine; indeed, some of the samples proved to be dyed very heavily with an aniline dye. We hope the public will exercise its commonsense in this matter and abandon the silly criterion of colour in regard to a number of articles of food, more particularly in regard to milk, and will demand this natural food in its natural condition. The infant should be spared the aniline dye and his guardians should see that such is the case. An Act of Parliament is needed which besides providing against the addition of water and the abstraction of fat shall prohibit under severe penalty the addition of any foreign substance whatever to milk.

THE MEDICAL SUPERVISION OF NURSLINGS IN FRANCE.

THE serious political problem presented by the stationary condition of the population of France has directed attention to the best means of checking the great infantile mortality. Hence has arisen the regular medical supervision of infants, termed "*Consultations de Nourrissons.*" In the *Archives Générales de Médecine* of May 16th Professor Budin has given an interesting account of the origin, organisation, and results of this system. When "*chef de service*" at the Charité Maternity he was struck with the high mortality of the infants after they they left hospital. When the mothers returned home they had no proper guidance and made mistakes in nursing with disastrous results. In 1892 Professor Budin asked the director of the Assistance Publique for permission to see once a week the infants who had been born in his hospital in order that he might direct the mothers as to their nursing and when suckling was insufficient supply good sterilised milk. After some opposition on the grounds of expense permission was granted and the "*Consultation de Nourrissons*" was founded. It is organised as follows. The mothers leave the hospital trained to suckle their infants and receive a card on which are marked the date of birth and the weight of the infant. Children entirely nourished at the breast are brought for inspection once a fortnight, but those dependent, partially or entirely, on sterilised milk are brought once a week. The infant is weighed each time and the result is marked on the card. Any necessary advice is given and the mother is encouraged to continue to suckle. This clinic Dr. Henri de Rothschild has aptly termed the "*école des mères.*" If the maternal milk is insufficient sterilised milk is prescribed on the card in definite quantities. The infants attend the "*Consultation*" until the age of two years. Each card shows at a glance the life-history of the child—the curve of increase of weight, the quantity of sterilised milk taken, and particulars as to dentition, difficulties of weaning, and illnesses. Professor Budin's "*Consultations*" have proved such a success that similar ones have been founded all over France. Dr. Dufour, who founded one at Fécamp in 1894, gave it the name of "*Goutte de Lait,*" which has become general. The results obtained are certainly remarkable. In France infantile mortality is high. In the years 1896 to 1900 from 160 to 170 per 1000 of the infants born died in the first year of life. The causes of the deaths in the first year of life in the towns of France are distributed as follows per 1000: gastro-intestinal affections, 385; affections of the respiratory system, 147; congenital debility, 171; tuberculosis, 25; contagious diseases, 49; and other causes, 223. Thus the most important causes are gastro-intestinal affections. Now at Professor Budin's "*Consultation*" the extraordinary result has been achieved of reducing mortality from these last affections to zero. In the years 1892 to 1898 only a single death occurred from gastro-enteritis and even this was a further proof of the value of the system. The mother left the child at a *crèche* where he received bad milk and contracted diarrhœa. He recovered but he was sent a second time to the *crèche* where in the same way he contracted "infantile cholera," which proved fatal. Subsequently to 1898 only one other death from diarrhœa has occurred and in that case too it was due to disobedience. In cases of congenitally feeble children special directions were given as to diet and to clothing. Since the year 1898 there have died only 93 (10·8 per cent.) out of 859 such children who weighed at birth less than 2500 grammes. The mortality of the children brought for consultation is much lower than the general mortality. Thus in the years 1898, 1899, and 1900 the former for the first year of life was only 46 per 1000, while that of Paris generally was 178. For pulmonary diseases the mortality was 17 while that of Paris was 32. In the towns of France "*Consultations de Nourrissons*" have also given excellent results. For example, in Saint-Pol-sur-Mer the deaths of infants in the first year of life per 1000 births was for the five years ending 1902 288; in 1903, after the establishment of a "*Consultation*," it fell to 209; and in 1904 to 151, in spite of the very hot summer. In Arques there was a similar diminution from 190 to 101 and 112 for the years 1903 and 1904 respectively. In the latter year the mortality in the neighbouring communes of Blendecques, Wizernes, and Longuenesse, where no "*Consultation*" existed, was respectively 136, 190, and 200. Moreover, in Arques, while the general mortality in the years 1903 and 1904 was that stated above, that of the infants brought for consultation was still lower—only nine and 34 respectively. Professor Budin attributes these surprising results largely to the enjoining of suckling. At the Clinque Tarnier 95 per cent. of the children are nourished at the breast, partly or entirely. In the feeding of infants Professor Budin regards the weighing machine as the great guide as to whether sufficient milk is being taken or not. If the infant is not gaining weight normally and there is nothing pathological to account for this the quantity of milk must be insufficient. Weighing the child before and after taking the breast may show that the quantity yielded is too small. Then sterilised milk must be used to supplement the maternal milk. On the other hand, it is important to avoid giving too much milk, which is a greater evil than giving too little for a short period. The former mistake will cause digestive disturbances but the latter only a temporary arrest of growth. As to the quantity of cows' milk required daily by a normal infant Professor Budin's extensive experience has led him to formulate the useful rule that the amount corresponds accurately to a tenth of the weight of the body. He uses milk sterilised in a water-bath at 100° C. In a dozen years he has had at his "*Consultation*" only a single case of rickets, and that slight, when the mother had not followed his advice; one case of eczema; and not one of scurvy.

THE subject of Tuberculosis of the Kidney was chosen by Dr. Howard A. Kelly, Professor of Gynæcological Surgery in the Johns Hopkins University, Baltimore, for his address delivered on June 8th before the British Gynæcological Society and published in abstract at p. 1630 of our present issue. There was a good attendance, about 80 members of the society and their friends being present, and subsequently a conversazione was held. Before the delivery of the address Dr. Howard Kelly was entertained to dinner at the Café Monico by Dr. H. Macnaughton-Jones. Amongst those present at this dinner were Dr. W. Alexander of Liverpool, Sir W. J. Sinclair of Manchester, Mr. Watson Cheyne, Dr. W. Duncan, Dr. J. H. Swanton, and Professor J. W. Taylor of Birmingham.

THE Cavendish lecture of the West London Medico-Chirurgical Society will be delivered on Friday, June 23rd, at 8.30 P.M., in the town hall, Hammersmith, by Dr. J. F. Goodhart, who has taken as his subject, Disease of the Heart. The usual conversazione, with surgical exhibits and a smoking concert, will be held by the West London Medico-Chirurgical Society upon the occasion.

DR. Clement Godson has been elected a corresponding member of the Società Italiana di Ostetricia e Ginecologia. Professor Pasquali, the President, in making the announcement refers to "the first successful Cæsarean operation performed in Great Britain after the Porro method which helped so much to render this form of operation acceptable in England."

AT the meeting of the weekly board of the Royal Free Hospital held on June 14th Mr. Charles Burt tendered his resignation of the post of chairman, which he has held for the past ten years. Mr. C. W. Blackman was appointed as his successor, Mr. Burt retaining the post of treasurer.

THE annual banquet of the Association of British Postal Medical Officers will be held in the Whitehall Rooms of the Hôtel Métropole, London, on Thursday, July 13th, at 7 for 7.30 P.M. The President, Dr. John Brown, will occupy the chair.

THE NEW KING'S COLLEGE HOSPITAL.

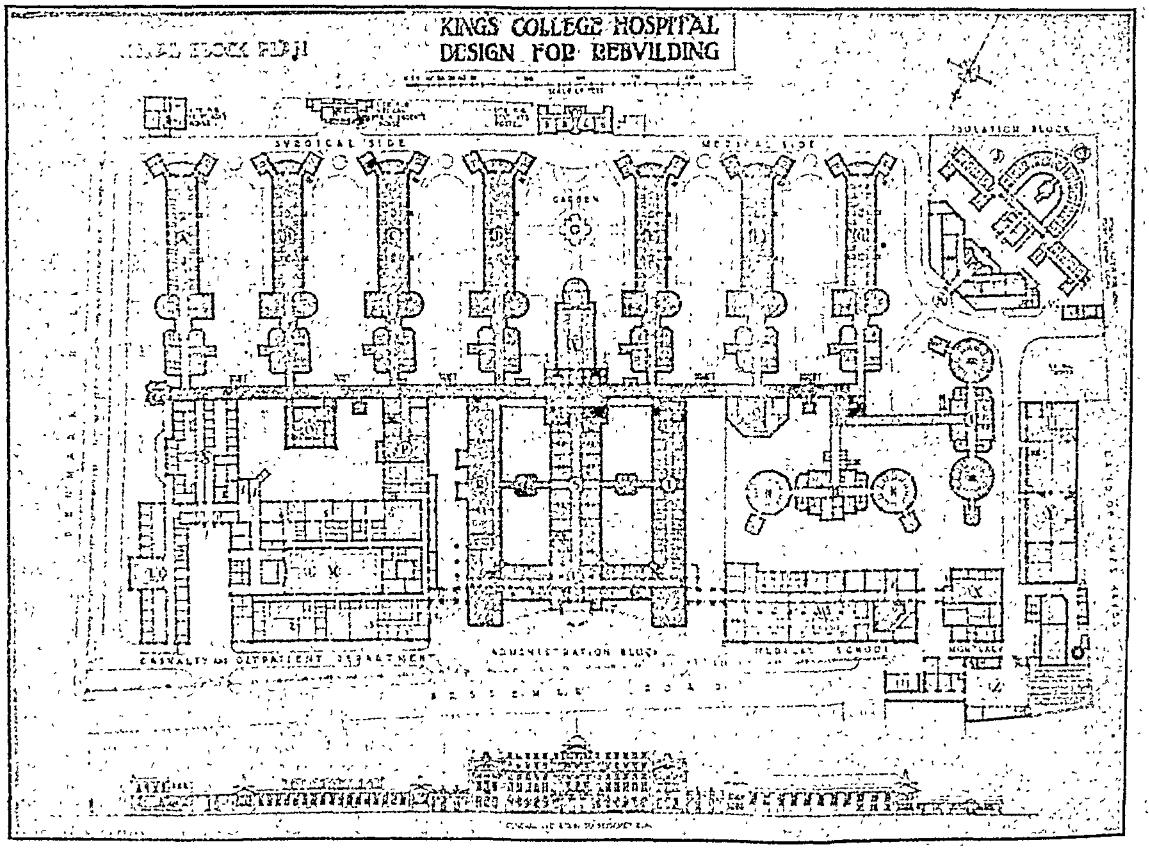
WE append an illustration of the plan of the new buildings of King's College Hospital. The idea which the architect set himself to carry out is described in his official report as aiming at unifying the nursing and general administration of the hospital, while reducing to a minimum the labour attendant on such services:—

> The vertical axis of the hospital, from north to south, upon the lower floor of the sick wards, suggested by the contour of the site (which rises rapidly towards the south) is occupied by the official nursing staff. That is to say, the sister matron's apart- [illegible] expenditure of [illegible]

The architect calls particular attention to the segmental form of plan for the isolation block, which he describes as the result of the study of Paris examples. He says:—

> First, the position on the site lends itself in a peculiarly appropriate way to this form, presenting the following advantages: (A) as taking up the least amount of site space; (B) of securing absolute privacy; (C) securing direct *cross ventilation* to each cell; (D) it procures for each cell a due amount of available sunlight; (E) complete supervision and nursing from both sides. In fact, the proposal,

which can only be considered as tentative, is full of suggestive possibilities—not the least practical being that one-half of the wards might be built in the first instance. Direct cross ventilation is secured by keeping the nursing corridor at a lower level than the wards, thus securing an open space above, while on the upper floor the ceiling of the corridor becomes a flat with no intervening space. Friends can visit the patients by an outside access and see them from the balconies, which are also available for outside nursing and for the removal of evacuations. Some of the cells have been arranged to communicate when it may become necessary to isolate the nurse as well as the patient, or where it may be necessary to isolate a whole family. We observed in Paris with interest the custom of taking in a mother with a sick child, the former, of course, having to conform to regulations. By the arrangement of this plan ducts and their cleaning can be avoided and unfettered ventilation secured under control by louvres, according to the directions of the wind. The heating would be by hot-water radiators or, if thought desirable, in the case of the cells by electric radiators. The system of cells is doubled so that every pair are parted by a cross wall, the remaining part being metal glazed screens; the doors and windows are of metal construction and glazed; the patients cannot open these doors, which are operated only by the nurses. The blinds are outside, as also are the blind cords. Each cell will have its own sink, water-supply, gas-jet, and electricity for sterilisation, as well as steam jets also available for a like purpose. The dado around the cells and corridors will be of fire-clay glazed both sides, measuring 4 feet × 2 feet × 1 foot 6 inches. The duty room and sick room are centrally placed and here the nickel plates, cups, &c., are sterilised after use. The patient is bathed in his cell and the dirty linen is put into a cylindrical box and removed for disinfection. The arrangements for convalescents are located as before described in circular rooms and isolated from the ward block, with their own sanitary conveniences. The centre part is occupied by the entrance and the receiving and robing rooms and bed lift, while on the upper floor an operation room has been provided, with the annexes. The economy of the isolation hospital is complete in itself and it is cut off from the general hospital by surrounding walls and gates with a complete zone.



It will be seen that the great novelty of the new hospital is the isolation block (J) which has been modelled, with important modifications, upon the Pasteur Hospital, Paris. It is unnecessary to give in detail the features of the new building because the appended illustration so clearly conveys both the conception of the architect and his achievement. The whole building has been most carefully thought out so as to combine economy with efficiency and, so far as human forethought can provide, the new hospital ought to be a model. The architect is Mr. W. A. Pite, F.R.I.B.A., and we congratulate him upon the happy combination of the æsthetic with the useful which is displayed in his design.

The following is the reference table to the block plan :—

SURGICAL SIDE.

Block A.—Lower, middle, and upper floors: Future extension.

Block B.—Lower, middle, and upper floors: Men.

Block C.—Lower and middle floors: Women. Upper floor: Gy cology.

Block D.—Lower floor: Children. Middle floor: Women. Up floor: Maternity.

MEDICAL SIDE.

Block E.—Lower floor: Children. Middle and upper floors: Wome

Block F.—Lower, middle, and upper floors: Men.

Block G.—Lower, middle, and upper floors: Future extension.

Block H.—Lower floor: Eyes. Upper floor: Ears, throats, a skins.

Block I.—Lower and upper floors: Future extension.

Block J.—Isolation block.

Block K.—Isolation block, administration, and nurses' home.

Block L.—Casualty department.

Block M.—Out-patient department: 1. Waiting hall. 2. Surg section. 3. Ophthalmic out-patient section. 4. Gynæcological a Children's section. 5. Medical section. 6. Ear and throat secti *Note.*—The Dental section is over Nos. 4, 5, and 6, and the electri section of out-patients' department is over Block N.

Block N.—Bathing establishment. Electrical section of out-patie department over.

Block O.—Three operation theatres.

Block P.—Dispensary; surgical clinical theatre over; gynæcologi operation theatre over.

Block Q.—Medical clinical theatre.

ADMINISTRATION BLOCK.

Block R.—Ground floor: Nurses' dining rooms. First floor: Nurse recreation rooms. Second and third floors: Nurses' bedrooms.

Block S.—Ground floor: Common rooms, resident medical officers common rooms, hospital clerks and dressers. First floor: Matron department. Second floor: Servants' bedrooms.

Block T.—Ground floor: Resident medical officers. First, entreso second, and third floors: nurses' bedrooms.

Block U.—Ground floor: Secretary's department and staff room First floor: Sister, matron, &c. Second and third floors: Nurse bedrooms. Fourth floor: Nurses' bedrooms (extension).

Block V.—Linen department: future chapel over; future roof garde over. *Note.*—The kitchen a and the servant living rooms occupy the base U, and the court between same. The porter's [illegible] Block T.

Block W.—Pathological department, medical school buildings, an students' clubs.

Block X.—Post-mortem department.

Block Y.—Laundry department.

Block Z.—Out-buildings.

Mr. Gordon Hooper, L.D.S. Eng., of Khartoum has been appointed Dental Surgeon to the Egyptian Arm and the Soudan Government.

THE INDIAN MEDICAL SERVICE ANNUAL DINNER

THE officers of the Indian Medical Service held their annual dinner on June 8th at the New Gaiety Restaurant Surgeon General JAMES CLEGHORN, C S I, being in the chair In addition to the usual loyal toasts the toast list was as follows "The Sister Services," proposed by Surgeon General Sir A C C DE RENZY, K C B and responded to by Inspector General HERBERT M ELLIS R N, Director General of the Royal Navy Medical Service Surgeon General A H Keogh, C B, Director General of the Army Medical Service, was also to have responded but at the last moment was unavoidably prevented from being present "The Guests," proposed by Surgeon General A M BRANFOOT, C I E, and responded to by Sir RICHARD DOUGLAS POWELL, Bart, K C V O, President of the Royal College of Physicians of London "The Indian Medical Service,' proposed by Mr JOHN LANGTON, F R C S was responded to by the CHAIRMAN who said "I have much pleasure, on behalf of the service, in thanking Mr Langton for the [illegible] proposed the toast [illegible] permission, to say a f[illegible] e in which I have passed the best years of my life, but before doing so I would explain that this is the first occasion on which I have had the opportunity of being present at the annual dinner and when the committee, through Lieutenant Colonel Freyer, asked me to preside I felt that as a late Director-General of the service it was my duty, as it was a pleasure, for me to accept the honour As you are aware, we have learned many things in India, but the art of public speaking is not, as a rule, one of those we have acquired—perhaps we are better without it—particularly on an occasion of this kind, when I take it we meet more to revive the memories and renew the friendships of the past than to make speeches These meetings also help us to realise that although we are divided into many departments, both officially and geographically, we are one service with common interests and all aiming to maintain and continue the honourable traditions of that service, and as a consequence the prestige of our nation and government among the different races of India Those traditions carry us back to the time of the Emperor Shah Jehan, when as I have read, the first concessions granted to the Honourable East India Company were obtained through the influence of one of the Company's medical officers named Boughton who, after his successful treatment of a daughter of the Emperor, was asked to name his own reward, when he replied that the only remuneration he would accept was an order granting to the Company the privilege of trading in Bengal free of duty and of planting factories in the interior of the country Since then the service by its influence on the people, through its medical work, has been [illegible] government and a long roll of [illegible] themselves in the various pos[illegible] have held One occasionally hears or reads uncomplimentary remarks with regard to our work in the field of original research and of the slow development of a complete sanitary organisation, but we who know the local conditions and circumstances understand the difficulties which surround the path of progress in particular directions Laboratories are, I understand being established by the Government and other facilities are now available for the pursuit of original investigations and I have no doubt that in due course good results will follow Hitherto we have been making bricks without straw—we early mastered that art—and though the products may not have been equal to the finished article we have been able to meet [illegible] government [illegible] the number [illegible], hospitals [illegible] unknown out of India, they are certainly not realised, and our work in connexion with the establishment and supervision of the institutions associated with the revered name of Lady Dufferin has been eminently successful All this medical work has overspread the whole of India and Burmah, it has exercised a more beneficial influence over the people than any other agency at present in operation and it has developed a sympathetic and kindly feeling between the members of the service and the natives of India, a feeling, moreover, that the British Government is a beneficent one On the other hand, we have become the guardians and reformers of the criminal class The connexion between medical work and the administration of jails is not quite apparent to the ordinary observer—but India is full of anomalies and I suppose as the civil surgeon was there it was considered to be economical and advantageous to utilise his services as superintendent of the district jail—and practically the whole of the jail department has grown up and developed under selected officers of the service Our ordinary duties are occasionally varied by a call to meet the requirements and exigencies of war, famine, and pestilence and, as occurred lately, all three may come at once Our resources were then strained and assistance, in the case of plague, had to be obtained from England As we make bricks without straw it is needless to say that all the institutions we manage are worked on economical lines—and the various duties are discharged without any ostentation or particular fuss—things are taken as a matter of course and whether we are employed on military or civil duties we try to do the work set before us to the best of our ability The manifold duties and responsibilities which devolve on the service and the unique opportunities which occasionally offer to the man with special talents or capabilities, these, combined with the pay and pension, are the main inducements which attract men to the service—but there are others not so apparent We enter the service at an impressionable age—in a land full of mysteries, with customs and beliefs different from our own Life in such a land modifies our ideas broadens our views, and deepens our sympathies The responsibilities we have to face develop the character and tend to make men of us There are of course, drawbacks, with them we are well acquainted, but, on the whole, I think we made a wise choice in selecting the Indian Medical Service as a career '

Lieutenant Colonel P J FREYER to whom the organisation of these dinners is due, being called upon made some remarks which he humorously characterised as "proposing his own health ' He received musical honours

The following officers were present —*Surgeon Generals* A M Branfoot C I E, J Cleghorn, C S I, Sir A C C De Renzy, K.C B, C Sibthorpe C B, and P W Sutherland *Colonels* W E Oates, W Gray D E Hughes, C H Joubert, G S Sutherland J S Wilkins, and W A S Wynne *Lieutenant Colonels* J Anderson, W H Cadge, G W P. Dennys P J Freyer I B Lyon C I E, D P MacDonald, J Moorhead, W Owen W H Thornhill, J F Tuohy, H G L Wortabet and P A Weir *Majors* R Bird, W S Caldwell, J T Calvert, B H Deare, F J Drury, G F W Ewens G H Fink, F A Hugo J G Jordan R C MacWatt, W H B Robinson H A Smith and L Wilkinson *Captains* S Anderson F L Blenkinsop H R Brown, T H Foulkes E D W Greig, W A Justice C A Lane A E H Pinch, R Selby J Stephenson, and A W C Young

An excellent dinner and after dinner speeches of a reasonable length combined to make the occasion as pleasant and as successful as its predecessors

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ELECTION OF MEMBERS OF COUNCIL

ON Thursday, July 6th, an election of four members of Council will be held by the Fellows of the Royal College of Surgeons of England Three of these vacancies will be occasioned by the retirement in rotation of Sir Henry G Howse Mr Edmund Owen, and Mr Rickman J Godlee, and the fourth by the resignation of Sir Alfred Cooper The following list of the members of the Council gives the date at which each member will retire The date of the first election is given in every case in which the member has been elected to the Council more than once Mr J Tweedy having been re elected President in 1904 will have another year of office

Retire in 1912 Mr H Gilbert Barling, Birmingham General Hospital, Mr Anthony A Bowlby, St Bartholomew's Hospital, and Mr Frederic S Eve, London Hospital

Retire in 1911: Mr. H. T. Butlin, St. Bartholomew's Hospital (first elected 1895); Mr. G. H. Makins, St. Thomas's Hospital; and Mr. C. T. Dent, St. George's Hospital.

Retire in 1910: Professor Howard Marsh, St. Bartholomew's Hospital (first elected 1892); Mr. J. H. Morgan, Charing Cross Hospital; and Mr. H. H. Clutton, St. Thomas's Hospital.

Retire in 1909: Mr. A. W. Mayo Robson, Leeds Infirmary (first elected 1893); Mr. W. Watson Cheyne, King's College Hospital; and Mr. R. Clement Lucas, Guy's Hospital.

Retire in 1908: Dr. J. Ward Cousins, Royal Portsmouth Hospital (first elected 1895); and Mr. A. Pearce Gould, Middlesex Hospital.

Retire in 1907: Mr. H. W. Page, St. Mary's Hospital; and Mr. C. W. Mansell Moullin, London Hospital.

Retire in 1906: Mr. J. Tweedy, President, University College Hospital (first elected 1892); Mr. F. Richardson Cross, Bristol Royal Infirmary; Mr. Henry Morris, Middlesex Hospital (first elected 1893); and Mr. John Langton, St. Bartholomew's Hospital (first elected 1890).

Retire in 1905: Sir Henry G. Howse, Guy's Hospital (first elected 1889); Mr. Edmund Owen, St Mary's Hospital; and Mr. Rickman J. Godlee, University College Hospital.

Monday, June 12th, was the last day for receiving nominations and we understand that there are only six candidates for the four vacant seats. They are: Mr. Owen and Mr. Godlee, who are applying for reappointment; Mr. C. H. Golding-Bird, Mr. Andrew Clark, Mr. W. Bruce Clarke, and Mr. W. Harrison Cripps. It is a long time since there have been so few candidates for four vacant places. There can be only two unsuccessful candidates.

The Fellows' dinner held in 1904 was very successful and it has therefore been decided to hold a Fellows' dinner again this year. As the space available is limited it may be necessary to ballot for places but all applications for tickets should be made before June 22nd.

HOSPITAL SERMON.

By REV. C. H. GRUNDY, M.A.,

VICAR OF ST. PETER'S, BROCKLEY.

"Gifts of healing"—I. Cor. xii. 9.

ONCE a year all party strife ceases in the religious world of London. No word of bitterness issues from the pulpits of London to-day. The question is not "What body of Christians do I belong to?" but "What can each one do to relieve the mass of suffering humanity in this great metropolis, larger in its population than Babylon, Thebes, or Rome ever was?" Hushed is the voice of controversy in the presence of disease and pain. The "deep sighing of the poor" in their anguish reaches all our ears, as from thousands of pulpits the call goes out to help men, women, and children in their need, struck down by accident or visited by disease. Their extremity is the measure of our sympathy and their weakness the strength of their claim upon us. There are countless opportunities for pain in the human body, so that the wonder is that health is sustained at all. Huxley says: "The human body is an army. Each cell is a soldier. An organ is a brigade. The central nervous system is the headquarters and field telegraph. The alimentary canal and circulatory system are the commissariat. Each cell has its life, duties, waste, repair, growth, and decay."

What complex beings we are! The phrase "*being ill*"—who does not know what that means, in himself, in loved ones, in the tender work of nursing, in the hours of agony when the doctor whispers "Nothing more can be done"? People in rude health joke sometimes about "not believing in doctors," but what a panic there is in the house the moment someone is smitten down by illness. The sudden stroke, the epidemic, the collapse from overwork, the wasting disease, the young wife hovering between life and death that another soul may enter upon earth, the little child at school one week and at death's door the next, the stranger calling to break the sad news at home that the husband has met with an accident in the street and is now in hospital; how familiar all these are to us, yet what anxiety, sorrow, and dread they represent. A serious illness taxes to the utmost all the capacities of even a well-to-do household. Things to be bought, thought of, borrowed, attempted; th nights of watching, the days of consultation, the vis of the specialist, the tension of the climax, the j of hope, and the weary convalescence—what an exper ence for the members of the comfortable home. Wh gratitude afterwards to the patient doctor whose sk has saved your darling! But where did he learn it al What training made him calm and resourceful and read with the best and latest treatment in that hour of miser when all else seemed to fail? You owe the life of your love one to the hospital. It was *there* that the rescuer of your dea one was taught what to do, and when to do it, and how to d it. You owe ransom money to the hospitals, for withou them there would have been the empty chair beside you hearth. Year by year they supply men able, qualified experts in their work, devoted to their duty, responsive t the call of suffering, and quick to diagnose and to act.

There is no band of men more unselfish, more untiring more thoughtful, more capable than the brotherhood of th medical profession in London. Often—very often—no fe is received by them after weeks of tender, assiduous attentio to some critical case. These are the saviours of humanit and their success is due to the schools of the hospitals fo which I plead to-day. Among the noble army of medicin and surgery some names are remembered. They have struc the popular imagination. What recollections are recalled b names like Paget, Lister, Horrocks, Jenner, Gull, Treves, an many others which could be mentioned. If the Church ha its saints the hospitals have noble benefactors of mankind If the Church points out salvation for the souls of men let u not forget what the hospitals have done for their bodies Christ was the healer of the body as well as the soul and th hospitals in His name undertake the care of their bodies. Th hospital is the sick room and the invalids' shelter amongs the poor. It would do you good to go to a children' hospital, say, the one in Great Ormond-street, and see patient, sweet, clean child in its dainty cot, suffering from say, hip disease, and then go and see the dirty squalid hom from which the child came.

What would Whitechapel do without the 840 beds of tha splendidly managed hospital—the London Hospital—willin to receive the crowds of sick from one-roomed homes? Ho many lives have been saved at Guy's of railway men hal killed on the shuntings of two great railway companies What an awful thing for Westminster or the locality roun St. Thomas's if there were *no hospitals*! You woul double your subscription if you realised the boon t the masses of this great metropolis. The scientifi gifts of healing are the glory of England and the inestim able blessing of the poor. London with its wealt should not be content with a paltry £60,000 as its respons to the annual appeal. £100,000 would be an easy and willing gift on a day like this did men and women realis *their duty to the poor* and the Christ-like work done by th hospitals in this city of suffering.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 16, 1827.

As the opinion which we form of the nature of a disease must be true or untrue, and as the treatment is founded upon that opinion, hence arises the absolute necessity o possessing correct principles of pathology, that dogmatism may be avoided on the one hand and empiricism on the other; or rather, that we may avoid a series of hazardous experiments on the health and lives of confiding patients, ignorant of the imperfections of the professors of an art, which has been too long concealed under a language almost as incomprehensible, to common minds, as the hieroglyphics of the ancient Egyptians; yet all that is really known, in modern medicine, might be expressed in a few plain English words, the rest being merely verbiage, a part of the mummery and mystery of scholastic and collegiate sophistry. Indeed, no part of human knowledge has been till recently kept so completely concealed from the public view as medicine, and this is the reason why some of its professors have risen to the highest distinctions without substantial attainments. The public can judge of the abilities of a barrister, but their ignorance of the elements of physic utterly prevents them from forming anything like a right estimate of the powers of a physician, as far as the exercise of his art is concerned. Dr. Johnson remarked, that the history of the means by which some physicians became extensively popular, would be extremely amusing; but it might be more truly said that it would be a most lamentable exposure of the frailties of the human mind and heart, by showing that men had held responsible and even sacred situations, without the practical acquirements necessary for the discharge of those duties which relate to the lives of patients and the happiness of their friends, and which, indeed, in some cases, involve the very best interests of society; for example, where the health of public characters is at stake. It would be highly advantageous to the public, and likewise to the best part of the medical profession, if the elements of modern medicine were made a portion of the liberal education of every gentleman, for then medical men and medical measures would be under the wholesome control of public opinion, so that practitioners would be estimated by their merit, and some of our corporate institutions would undergo those salutary changes which are imperatively demanded by the increased intelligence of the age. If any thing requires to be narrowly watched, it is the corporate spirit which is so apt to make men, in pursuing their own advantages, lose sight of the general welfare. One cause of much of the evil existing in society, is the selfishness with which we attempt to compass our ends, not duly considering what we owe to the interests of others; and another cause of evil, is the indifference or indisposition to maintain those strict rules of justice, by which the rights of public institutions are upheld against the encroachments of sinister designs.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8528 births and 4051 deaths were registered during the week ending June 10th. The annual rate of mortality in these towns, which had been 14·4, 14·6, and 14·7 per 1000 in the three preceding weeks, declined again to 13·5 per 1000 last week. In London the death-rate was 13·8 per 1000, while it averaged 13·4 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·5 in Barrow-in-Furness, 5·0 in Great Yarmouth, 5·9 in Leyton, 6·2 in Hornsey, 6·7 in Reading, 6·8 in Handsworth (Staffs), 7·7 in Grimsby, and 7·8 in Rotherham; the highest rates were 17·5 in Plymouth, in West Hartlepool, and in Tynemouth, 20·0 in Smethwick, 20·2 in Hanley, 20·3 in Salford, 22·8 in Middlesbrough, 23·1 in Oldham, and 23·3 in Merthyr Tydfil. The 4051 deaths in these towns last week included 413 which were referred to the principal infectious diseases, against 442, 414, and 410 in the three preceding weeks; of these 413 deaths, 144 resulted from measles, 109 from whooping-cough, 60 from diarrhœa, 42 from diphtheria, 26 from scarlet fever, 25 from "fever" (principally enteric), and one from small-pox. No death from any of these infectious diseases was registered last week in Leyton, Brighton, Bournemouth, Southampton, Northampton, Great Yarmouth, Burton-on-Trent, King's Norton, Aston Manor, Leicester, York, or Tynemouth; while they caused the highest death-rates in West Bromwich, Smethwick, Coventry, Derby, St. Helens, Middlesbrough, West Hartlepool, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in West Bromwich, Smethwick, Coventry, Derby, St. Helens, Sheffield, Middlesbrough, and Merthyr Tydfil; from scarlet fever in Oldham; from diphtheria in Rochdale and West Hartlepool; and from whooping-cough in Tottenham, East Ham, Walthamstow, Hanley, Preston, Middlesbrough, and Sunderland. The mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. One fatal case of small-pox was registered in Derby, but none in any other of the large towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been 15, 10, and nine on the three preceding Saturdays, was again nine on Saturday, June 10th; three new cases were admitted during the week, against three, none, and one in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of last week was 2285; against 2211, 2200, and 2267 at the end of the three preceding weeks; 269 new cases were admitted during the week, against 319, 312, and 351 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 226, 218, and 235 in the three preceding weeks, declined again last week to 191, but were 34 above the number in the corresponding period of the preceding year. The causes of 33, or 0·8 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Salford, Bradford, Leeds, Hull, Newcastle-on-Tyne, and in 50 other smaller towns; while the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·7, 18·1, and 16·9 per 1000 in the three preceding weeks, declined again to 16·4 per 1000 during the week ending June 10th, but was 2·9 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·8 in Leith and 14·9 in Aberdeen to 20·1 in Paisley and 21·3 in Perth. The 551 deaths in these towns included 23 which were referred to whooping-cough, 17 to measles, 14 to diarrhœa, four to diphtheria, three to "fever," and one to scarlet fever. In all 62 deaths resulted from these principal infectious diseases last week, against 76, 76, and 80 in the three preceding weeks. These 62 deaths were equal to an annual rate of 1·8 per 1000, which was 0·4 per 1000 above the death-rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 24 in each of the two preceding weeks, declined last week to 23, of which 16 occurred in Glasgow, four in Edinburgh, and two in Paisley. The deaths from measles, which had been 26, 30, and 33 in the three preceding weeks, fell to 17 last week, and included 14 in Glasgow, and three in Edinburgh. The fatal cases of diarrhœa, which had been seven and 16 in the two preceding weeks, declined again last week to 14, of which seven were registered in Glasgow, three in Edinburgh, and three in Dundee. The deaths from diphtheria, which had been three, seven, and one in the three preceding weeks, rose again to four last week, and included three in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 83, 107, and 88 in the three preceding weeks, were 89 last week, and were 21 in excess of the number in the corresponding period of last year. The causes of 22, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·5, 19·0, and 19·4 per 1000 in the three preceding weeks, declined again to 19·3 per 1000 during the week ending June 10th. During the past four weeks the death-rate has averaged 19·3 per 1000, the rates during the same period being 14·3 in London and 16·0 in Edinburgh. The 140 deaths of persons belonging to Dublin registered during the week under notice were slightly below the number in the preceding week and included five which were referred to the principal infectious diseases, against six, four, and eight in the three preceding weeks; of these, three resulted from measles and two from whooping-cough, but not any from small-pox, scarlet fever, diphtheria, "fever," or diarrhœa. These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 2·0 in Edinburgh. The fatal cases of measles, which had been one and three in the two preceding weeks, were again three last week; the deaths from whooping-cough, which had also been one and three in the two preceding weeks, declined again last week to two. The 140 deaths in Dublin last week included 22 of children under one year of age and 51 of persons aged 60 years and upwards; the deaths of infants showed a decline, but those of elderly persons were considerably in excess of the number in the preceding week. Eight inquest cases and five deaths from violence were registered; and 60, or

more than 40 per cent., of the deaths occurred in public institutions. The causes of five, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING MAY, 1905.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·2 per 1000 of the population, estimated at 4,684,794 persons in the middle of the year. In the three preceding months the rates had been 5·9, 6·0, and 5·6 per 1000 respectively. The lowest rates last month were recorded in Paddington, City of Westminster, Hampstead, Stoke Newington, the City of London, and Greenwich; while the highest rates occurred in Shoreditch, Bethnal Green, Stepney, Poplar, and Wandsworth. Small-pox was rather less prevalent than it had been during the preceding month; of the 11 cases notified during May, four belonged to Camberwell, two to Lewisham, two to Woolwich, and one each to Hackney, Wandsworth, and Deptford. The Metropolitan Asylums hospitals contained nine small-pox patients at the end of last month, against 15, 20, and 16 at the end of the three preceding months; the weekly admissions averaged two, against four in each of the two preceding months. There was a considerable increase in the prevalence of scarlet fever last month; this disease was proportionally most prevalent in Fulham, Finsbury, Shoreditch, Bethnal Green, Poplar, and Wandsworth. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1941, 1997, and 2152 at the end of the three preceding months, had further risen to 2236 at the end of last month; the weekly admissions averaged 302, against 231, 272, and 266 in the three preceding months. The prevalence of diphtheria showed no appreciable variation from that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Hammersmith, the City of London, Shoreditch, Bethnal Green, Stepney, and Poplar. The Metropolitan Asylums hospitals contained 684 diphtheria patients at the end of last month, against 837, 788, and 719 at the end of the three preceding months; the weekly admissions averaged 89, against 118, 98, and 83 in the three preceding months. Enteric fever was slightly more prevalent than it had been in the preceding month; this disease showed the greatest proportional prevalence in Kensington, St. Marylebone, Hackney, Bethnal Green, Stepney, and Bermondsey. The number of enteric fever patients remaining under treatment in the Metropolitan Asylums hospitals at the end of last month was 80, against 105, 68, and 65 at the end of the three preceding months; the weekly [illegible] the two [illegible] ally most [illegible] Bethnal [illegible] cases of [illegible] ed four in Islington, three in Camberwell, three in Greenwich, and two each in Chelsea, City of Westminster, St. Marylebone, Finsbury, Southwark, and Deptford.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending June 3rd the [illegible] were register[illegible] in the three [illegible] 15·5, and 15[illegible] 6·6 in Hampstead, 10·1 in Wandsworth, 10·5 in Lewisham, 12·2 in Deptford, and 12·5 in Chelsea and in Greenwich, to 16·8 in Holborn, 17·3 in Southwark, 17·4 in Bethnal Green, 17·6 in Finsbury, 18·4 in Shoreditch, and 19·5 in the City of London. The 6304 deaths from all causes in London last month included 621 which were referred to the principal infectious diseases; of these, two resulted from small-pox, 228 from measles, 38 from scarlet fever, 36 from diphtheria, 212 from whooping-cough, 19 from enteric fever, and 86 from diarrhœa, but not any from typhus or from ill-defined forms of continued fever. No death from any of these diseases was recorded in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Chelsea, City of Westminster, Wandsworth, Deptford, and Woolwich; and the highest rates in Paddington, Fulham, Finsbury, Shoreditch, Poplar, and Battersea. The two fatal cases of small-pox both belonged to Lewisham. The 228 deaths from measles were 86 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Fulham, Holborn, Shoreditch, Stepney, Poplar, and Battersea. The 38 deaths from scarlet fever showed a decline of 14 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in Hampstead, St. Pancras, Finsbury, Shoreditch, Stepney, and Lewisham. The 36 fatal cases of diphtheria were only a little more than a quarter of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, St. Pancras, Bethnal Green, Bermondsey, and Greenwich. The 212 deaths from whooping-cough were 23 fewer than the average number in the corresponding periods of the ten preceding years; this disease showed the greatest proportional mortality in Hammersmith, Finsbury, Shoreditch, Poplar, and Southwark. The 19 fatal cases of "fever" showed a decline of 11 from the corrected average number; three of the deaths belonged to Islington, three to Woolwich, and two each to Kensington, Hackney, Stepney, and Southwark. The 86 deaths from diarrhœa were 13 in excess of the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Fulham, City of Westminster, Holborn, Bethnal Green, and Stepney. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 27 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 102 per 1000. The lowest rates of infant mortality were recorded in Hampstead, the City of London, Wandsworth, Deptford, Greenwich, Lewisham, and Woolwich; and the highest rates in Kensington, Chelsea, Islington, Finsbury, Shoreditch, and Poplar.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon J. Lowney to the *Dominion*, temporary. Surgeons: C. M. Woods to the *Pembroke*; J. G. Peebles to the *Victory*; T. W. Myles to the *Vivid*, additional, for disposal; F. F. Lobb to the *Albemarle*; and H. C. Woodyatt to Royal Marines, Plymouth.

ROYAL ARMY MEDICAL CORPS.

Major J. D. Ferguson, D.S.O., is appointed Instructor and second-in-command of the Depôt Training School at Aldershot, vice Major F. J. Greig, who is posted to Stirling for duty. Major H. J. Parry, D.S.O., Assistant Instructor and commanding A Company, is to be succeeded by Captain J. D. G. Macpherson, now under orders for Aldershot. Captain F. Ashe is appointed for duty with the 5th Division at Dover. Captain G. G. Delap, from Poona, and Lieutenant G. W. Heron are appointed to the London District for duty.

Lieutenant-Colonel J. G. MacNeece to be Colonel, vice W. O. Wolseley, deceased (dated June 4th, 1905). Lieutenant-Colonel D. Semple retires on retired pay (dated June 14th, 1905). Lieutenant G. W. Heron, from the Seconded List, to be Lieutenant (dated June 2nd, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

[illegible] (dated [illegible] to be [illegible]

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Ayrshire and Galloway: Surgeon-Lieutenant A. Young resigns his commission (dated June 10th, 1905). 1st Fifeshire: Honorary Assistant Surgeon J. Welsh resigns his appointment and is granted the honorary rank of Surgeon-Captain with permission to wear the prescribed uniform (dated June 10th, 1905). 1st Lancashire: Surgeon-Major T. M. Dawson to be Surgeon-Lieutenant-Colonel (dated June 10th, 1905).

Rifle: 1st Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Captain H. G. Thompson (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, 1st London Volunteer Infantry Brigade), to be Surgeon-Major (dated Sept. 4th, 1901). 1st (City of Dundee) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Major D. Lennox is appointed Brigade-Surgeon-Lieutenant-Colonel, and is borne as Supernumerary whilst holding the appointment of Senior Medical Officer of the 34th Field Army Brigade (dated June 10th, 1905). 1st (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Captain J. N. Marshall resigns his commission (dated June 10th, 1905).

DEATHS IN THE SERVICES.

Surgeon-Major-General John Warren, A.M.S., on June 4th, in his seventy-first year. He entered the service as assistant surgeon in 1857, was promoted surgeon in 1873, surgeon-major in 1873, deputy surgeon-general in 1883, and surgeon-major-general in 1893. He was in medical charge of the 15th Hussars in the Afghan War of 1878–80, including the advance to Khelat-i-Ghilzie and with the Thull Chotiali Field Force under Major-General Biddulph (medal). In the Egyptian War of 1882 he was in charge of No. 5 Moveable Field Hospital (medal and Khedive's star). He also took part in the Soudan Campaign in 1885 (mentioned in despatches and clasp). He retired in 1896.

Colonel William Owen Wolseley, R.A.M.C., on June 3rd. He joined the service as surgeon in 1880, became surgeon-major in 1892, brigade-surgeon in 1898, and surgeon-colonel in 1903. He served in the expedition to Ashanti under Sir Francis Scott in 1895 (promoted, bronze star). In the operations on the North-West Frontier of India, 1897–98, he was present with the Kurram Moveable Column, Tirah Expeditionary Force (medal with two clasps).

LORD ROBERTS'S APPEAL.

Lord Roberts has recently addressed an appeal to the nation for funds for providing a large extension of the system of rifle clubs. Why should not rifle-shooting and the use of the rifle be made a national pursuit and accomplishment? Indeed, being a matter of national importance, why should not the Government do its best to aid such an undertaking? Lord Roberts very pertinently points out that the independence of a State must rest not only on the willingness but on the ability of a nation to defend itself. He cites in illustration of this position his experience of what occurred in our late war in South Africa; and we may also call attention to the achievements of the Japanese in the present war in the Far East. The hatred of so-called "militarism" in this country, which is in itself perhaps a wholesome feeling, may be easily turned into an excuse for shirking an obvious duty. For ourselves we venture to think that it is not only right that there should be some system of obligatory military training on the part of the youth and young manhood of this country, but as medical journalists we hold that it would prove very beneficial from a hygienic and moral point of view. Little or nothing is done for the physical training of the young in this country, and there can be no doubt that a military training of some sort improves the health and physical vigour, while the discipline tends to develop the intelligence and to strengthen the manhood and character of a people.

PATHOLOGICAL EFFECT OF SHELL FUMES.

Dr. Ignatius Much, in a description of a *sauve qui peut* at the battle of Mukden, which he contributes to the *Kurj Warsz*, speaks of an intelligent soldier who was brought down by the fumes of a shell that exploded near him. When picked up he was found to have lost his sight, hearing, and speech. He is now partially restored to health. He sees, hears, and feels, but cannot speak.

THE WAR IN THE FAR EAST.

That Russia is willing to open negotiations with Japan is the great and absorbing news at the present time. It is, of course, quite premature to say that these negotiations will be the prelude to peace, but it is, at any rate, of hopeful augury that such may be the case. The continuance of a war marked by such recurring massacres and involving such wholesale suffering and financial losses as have attended the naval and military operations in the Far East has been growing more and more repugnant to the human conscience. The possible dawn of peace is consequently hailed on all sides as an event most devoutly to be desired. President Roosevelt has, by his able and tactful diplomacy, earned the gratitude of the civilised world by having initiated a hopeful movement in this direction. As regards the terms of any proposed settlement, there is in the meantime room enough for all kinds of conjectures and we may be sure that many will be put forward on which little or no reliance can be placed. All the world knows, however, what the defeats and losses have been on the side of Russia and the great successes which have attended the efforts of the Japanese to attain their end. We do not know how far the Czar and his Government may be influenced at the present time by the internal state of Russia, her finances, and the amount of sickness in her army in Manchuria, but that in any case Russia will have to face and to deal with the facts as they now stand is obvious. It is only fair to say that the Japanese policy has not hitherto been one of bluff and aggression but the Mikado's Government is nevertheless bound to secure as far as practicable a durable peace and to recuperate itself in some measure for the enormous sacrifices of life and money which it has incurred in this war. Beyond the fact that Admiral Rojdestvensky is progressing satisfactorily there is no medical news to record, nor is there likely to be any so long as everything is dominated and overshadowed by the hoped-for news regarding a prospect of peace.

Correspondence.

"Audi alteram partem."

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST.

To the Editors of THE LANCET.

SIRS,—In both the medical and lay press there has been lately much discussion concerning the practice introduced by a certain coroner of giving all medico-legal post-mortem examinations to a special pathologist. The Government of India has for many years recognised the value of this method and in Bombay and Calcutta the police surgeon does all post-mortem examinations of cases reported to the coroner. It is upon this report that, as a rule, the coroner decides whether it is necessary to hold an inquest. He sends in a written report of the post-mortem examination to the coroner which forms the basis of his evidence subsequently given on oath in the coroner's court. There is no question of fees as the coroner's surgeon receives a fixed salary. He is also lecturer on forensic medicine at the Calcutta Medical College, and the bodies sent to the morgue are used for the practical instruction of the senior students. I have held the post of coroner's surgeon during the past two years and during that time have made something like 400 post-mortem examinations, including numerous cases which were of great medico-legal interest. I am convinced that the ordinary practitioner would have found great difficulty in dealing with many of these cases which required not only knowledge of medical jurisprudence but also experience. To apply a phrase originally used in connexion with a totally different branch of human energy: a man is not necessarily making a post-mortem examination because he is cutting up a body. I will not go into details but will give one instance to explain what I mean. In cases of injury to the head it is better to examine the skull and brain before the thorax has been opened and the large veins severed. Those who only work from book knowledge would begin the body incisions under the usual directions given for making a post-mortem examination. Another important point concerning which the ordinary practitioner has little or no experience is the effect produced on the tissues by various poisons. The coroner's surgeon will, of course, have the assistance of an analyst in such cases, but in many cases he has to decide whether the appearances presented in the body before him point to poisoning and whether he ought at once to seal up the stomach, &c., ready to be sent to the analyst. Upon the post-mortem report many serious issues depend; often it is a matter of life or death to an accused. It stands to reason, therefore, that it is safer to employ a special pathologist with experience of many cases than to allow each post-mortem examination to be made by a different medical man and often, of necessity, by a medical man who has only made one or two such examinations in his lifetime. Another reason for employing a special pathologist is the experience which he gets in the matter of giving medical evidence in simple language so that it can be easily understood by the laymen composing the coroner s jury Many men who can explain the results of a post mortem examination in technical medical terms often fail to convey a clear idea of the important points to the jurymen This point is of even greater importance when the case passes *from the coroner s court to one of the higher courts of* justice

A third reason which I think is in favour of the new plan is the protection it offers to the public Many of the bodies upon which post mortem examinations are made are in a state of decomposition and highly septic As the coroner s surgeon in Calcutta is not allowed to engage in private practice there is no danger of his carrying infection to anyone else—a danger by no means absent when the post-mortem examination is made by a general practitioner who goes from the mortuary to visit his patients The question of fees or expense is not one that should be allowed to enter into a discussion of such general and scientific importance and a general practitioner ought not to feel hurt because special work is given to a man who is willing to devote himself to what, after all, *is not a very pleasant occupation*

I am, Sirs yours faithfully
J H Tull Walsh,
Lieutenant Colonel I M S

Old Catton Norwich June 12th, 1905

To the Editors of The Lancet

Sirs,—As a spectator at a recent inquest held by Mr Troutbeck at Wandsworth I was painfully impressed by observing the feeling that has arisen in South London between the coroner and the local profession A crowded court, the presence of two solicitors two counsel, numerous medical practitioners, and an adjourned inquiry, which lasted nearly three hours, would seem to point to a matter of grave public importance The inquest was, on the face of it, to find out whether a child had died from pneumonia or whether the death had been accelerated by an overdose of morphiæ in the medicine prescribed but the coroner suggested that his own conduct in not ordering the practitioner in attendance on the deceased to assist in making the necropsy was not the least of the matters imported into the case The medical interest lies entirely in the attitude assumed by Mr Coroner Troutbeck He asserted he was not fighting the medical profession though the presence of counsel instructed by the British Medical Association, the honorary secretary of the Medical Defence Union, and many medical practitioners in sympathy with Dr Miller hardly supported his statement But this was explained by him as due to the action of certain medical societies whose paid officials found it necessary to find something to show a reason for their existence He never refused to summon a medical witness if he thought his evidence would be of any use but he could not often ascertain its value before the opening of the inquest Might this not be in consequence of the attitude Mr Troutbeck has assumed? In other parts of the county of London coroners

observer of the latest phase of the deceased s illness should so assist, but Mr Troutbeck thinks otherwise His views of the capacity of the ordinary medical practitioner are, to say the least, not flattering As clinical evidence can only be furnished by his class clinical evidence is to be depreciated as much as possible For what other reason could such evidence be preferred second hand? In putting to the jury the one important question, viz, the cause of death, Mr Troutbeck laid down that the jury were to take the evidence of Dr L Freyberger that the clinical symptoms observed by Dr Miller were consistent with natural death rather than that of the latter that they were inconsistent Why were the jury necessarily to take Dr Freyberger s opinion on this subject? Dr Freyberger had previously stated that if the deceased had actually taken the quantity of medicine sworn to by the mother he could not "dissociate' that fact from the cause of death The coroner had himself said he did not believe the later statement of the mother, that no more than five teaspoonfuls had been administered It would have been thought that this opinion of Dr Freyberger was strongly confirmatory of Dr Miller s clinical observations

Anyway to put to the jury the opinion of a medical witness touching clinical phenomena when he had not been present in preference to that of one who had is treating clinical observations with scant respect and in this particular case the question the jury had to try rested almost entirely on what might have been observed during the last few hours of life The post mortem results were bound to be negative, as the quantity of morphine taken was admittedly small The most important points for the jury, in my opinion, were these A child had died who, in the opinion of the medical attendant, was suffering from narcotic poisoning, that attendant noticed at the bedside a bottle of medicine which was proved to contain morphine and out of which at least 20 teaspoonfuls had disappeared, instead of two or three, as had been ordered The mother swore that she had administered practically this quantity The pathologist stated that if these 20 teaspoonfuls had been given he could not "dissociate it from the cause of death Dr Miller gave evidence that in his opinion the latest condition of the deceased was only consistent with narcotic poisoning On these facts the jury found that the death was entirely due to *natural causes It might surely be argued by some that* the verdict was against the weight of evidence and that there had been misdirection on the part of the coroner

I am, Sirs, yours faithfully,
June 13th 1905 Barrister at Law

⁂ Colonel Tull Walsh hardly realises the situation which has prompted him to write an interesting letter No sensible people object to the employment of a special pathologist in suitable cases at a proper fee But the pathologist should be a proved expert, the public should not be *made to pay for him when his services are quite unnecessary,* and his evidence should not be regarded as replacing the clinical evidence of the medical practitioner last in attendance upon the case, a point well brought out in 'A Barrister at Law s letter —Ed L

THE PRINCIPLES OF HEREDITY

To the Editors of The Lancet

Sirs,—Interesting as is Dr Archdall Reid s new work I *cannot but think* it would have been more convincing had he refrained from divulging the data and reasons upon which he bases his theory Arguments like the following are too frequent 'It—i e the neo Darwinian theory of evolution by natural selection—infers that *as a rule* individuals who survive and have offspring are those which are better fitted to the environment in which they are placed than those which perish Now the sole criterion we have as to the fitness of an organism for its environment is by its continued existence Hence the statement amounts to this that as a rule individuals who have the best chance of surviving survive and those with the least chance perish

Dr Reid s views on alcohol are generally known, Landor well anticipated them in the words he puts in the mouth of Sergius in his conversation with Mahomet Forbid wine, indeed! God himself if he descended on earth and commanded it in a louder and clearer voice than that at which the creation sprang forth unless first he altered the composition both of body and soul would utterly fail in this commandment Many of Dr Reid s observations in so far as they relate to Jews and some other races are I believe, incorrect Briefly put, he contends that the Jews are, with impunity, moderate drinkers because all those likely *to suffer* have been eliminated by natural selection It is true that a Jewish abstainer is quite the exception and that among the older generation drunkenness is rare, however among the younger generation of English born Jews, at any rate it is by no means uncommon and its effects are precisely the same as among other persons I have had under my care Jev
delirium tremens and other
alcohol When exposed to mc
avoid controversy, I shall not say because of them—the Jew quite readily assimilates to his Gentile surroundings in this and other respects In other words, so far as the Jew is concerned he *has* been sober by acquirement" and can at any time "acquire' alcoholism There is no question here of elimination nor indeed, of any transmitted effects of

saying, "Litera scripta manet." Death certification is a thankless and generally a wholly unremunerative duty.

I am, Sirs, yours faithfully,
June 9th, 1905. A PROVINCIAL SURGEON.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

THE EXCURSION TO EVIAN-LES-BAINS.

(BY ONE OF OUR SPECIAL COMMISSIONERS.)

IT is a long journey from Vichy to Evian. We had a special train, an express train, that only stopped on rare occasions and was not delayed by the taking up or setting down of passengers. We started shortly after 3 P.M. and yet it was close upon 11 at night before we reached Geneva. The time nevertheless passed pleasantly and therefore quickly. Also, there was tea served in the train and later a very excellent dinner, so that it was no great hardship to be confined with agreeable company under such hospitable conditions. At Geneva there was only just time to drive to the hotels allotted to each of us and to seek much-needed rest. Next morning we had to be up early, for a special and large steamer, gaily bedecked with innumerable flags, was waiting and announced to start at 9 o'clock. The weather was cold and the sky was cloudy, but fortunately it did not rain, so that the visitors were able to stay on deck. Though Mont Blanc and the snow-clad Alps were hidden from view, still the nearer scenery and the lake itself were very beautiful. It was also a good idea to convey us to Evian by water, for this thermal station is seen to much greater advantage from the lake. Indeed, the principal impression is that of the favoured site occupied by the little town. It is situated on the edge of a vast amphitheatre formed by mountains and bordered by the lake. The old town itself is very small. Savoy is the poorest department of France, so that the old houses of Evian are picturesque rather than prosperous in appearance, but they are to a large extent hidden by the great and luxurious buildings connected with the springs. There still remain, however, six towers that formed part of the mediæval fortifications and these add greatly to the picturesque aspect of the place. Even from those times records have been preserved that show the waters were drunk as a cure for gravel and, further back in history, that they were appreciated by the ancient Romans. Nevertheless, it is only of late years that Evian has become a great international station attracting patients from all parts of the world. The modern growth and development of Evian may best be realised by glancing at the statistics. Thus in 1891 the number of bottles of Evian water sold amounted to 761,909; in 1895 this had increased to 1,478 477; in 1900 to 3,725,000; and in 1903 to 4,917,584. Every year new buildings are erected or old ones are enlarged. The great hotel and the vast bathing establishment still gleam and shine with their newness. Indeed, it is a relief to find that there are also close at hand some ancient tumble-down houses and cottages the walls of which are grey and mellowed by age and where all trace of polish had long since been worn away.

On landing our first visit was to the bathing establishment which, having been built quite recently, contains the very latest improvements. One special feature is that each bath room is divided into two compartments. The outer compartment is the dressing room and each dressing room has its own closet, so that there is no need to go down long corridors in a state of deshabille. Except for douches the patient undresses by the side of his bath. Provision is made for every sort of hydropathic treatment and there are also the necessary appliances for Dowsing and other light baths, and an x ray department. Then there is a staff of experienced masseurs and there is a room for mechano therapy as at Vichy.

After visiting all the baths and the pump room where the patients go to drink the waters the visitors ascended the hill-side to the Hôtel Splendide where a banquet had been prepared which was followed by many speeches and toasts. Among the first to speak was Sir JOHN W. TYLER who responded to the official toasts and then called upon Mr. G. A. BERRY to speak at greater length as he had a good command of the French language. Among other observations Mr. Berry said that there had been many international congresses but this gathering would become historic. They had enjoyed all the advantages of a congress and none of the disadvantages. They had exchanged ideas, they had talked over matters of mutual interest, but there had been no wearisome and formal debates.

Sir JOHN W. MOORE, on behalf of the Irish medical men, wished to express his thanks. He was particularly grateful to the ladies who had acted as hostesses. The success of the journey had exceeded all their hopes. They would never forget the days they had spent in beautiful France and the grace and the charm of their French sisters.

This speech brought up another Irish orator in the person of Mr. ARTHUR CHANCE, President of the Royal College of Surgeons in Ireland. It was on behalf of the Irish surgeons that he was anxious to express his thanks, and this not merely for the reception which they had had but more especially for what they had been able to see of the work done by the French surgeons in the French hospitals. Here they had admired and learnt much. Altogether the reception given was worthy of the nation and he could not say more. The French had taught them the significance of one of the words on their proud device. The British visitors now understood what was meant by "Fraternity." He raised his glass to that incarnation of hospitality, the general secretary of the receiving committee, Dr. Triboulet. Though the Irish were divided from France by two stormy seas a love founded on historical facts united them. Strong and ancient ties of affection subsisted and he hoped that French medical men would frequently visit Ireland. The whole heart of the Irish people would go out to greet them.

The MAYOR of EVIAN, M. RICHAT, expressed the hope that those whom he had the pleasure of welcoming on the present occasion would come back again to Evian and at no distant day. They would then see by the improvements effected year after year that the municipality and inhabitants of Evian did not tire in the endeavour to do good.

Dr. DUMUR, on behalf of the medical practitioners of Evian, drank to the British medical men and Dr. GAUTIER repeated the same toast on behalf of the medical practitioners of Geneva. Then, amid general applause,

Dr. TRIBOULET rose to reply and complained that too much had been said in his honour, and time did not allow him to explain in detail how all this honour, all these praises, should be divided among various different persons and different periods. It did not all come about spontaneously and simultaneously. There were modest beginnings and early efforts that should not be forgotten in the glow of the after success. What would have become of the idea if it had not been taken up in England by an English committee which gave them all an admirable lesson in discipline and in business-like qualities. It was the British organisers of the reception of the French medical men in London who had revealed the secret of success. The joy expressed by the British visitors to-day was the best recompense of the French organisers for having well learnt their lesson. He was aware that on all sides the satisfaction had been great and one of the reasons for this was that they had realised that for such undertakings it was essential to be not too young nor yet too old. Thus on the present occasion they had united the buoyant energy of Sir William Broadbent with that glorious example of perpetual youth presented by Professor Bouchard. But all these efforts on the part of individual members of the medical profession would not have met with the general support that had made their strength if they had not been seconded at every step by widespread publicity. The medical press had not only made known their desires and their invitations to all whom it might concern, but they could not forget the brilliant reception given to the French medical men in London by THE LANCET. He was glad to see present a representative of that great journal. He raised his glass in gratitude to the medical press.

Mr. ADOLPHE SMITH, who responded, said that he was pleased that the services of the press had been acknowledged. It was very easy and pleasant to-day to speak of *l'entente cordiale*, but there had been times when this cause was not so popular. There were unhappy moments when the political press was rendering but poor service to the cause of humanity by venomous comments on whatever misunderstanding or disagreement had arisen between nations. During these dark periods the scientific press continued as usual, speaking of the scientific attainments of their neighbours just as if there were no quarrel or disagreement in existence. This calm superiority of science in its love and devotion to humanity—a devotion that no political squabbling could disturb—served to steady the ships of State, storm tossed by the fleeting passions of peoples and politicians This internationalism of science occupied a large space in the columns of THE LANCET and it had done more than promote scientific knowledge, for it had helped to maintain peace

The whole party then proceeded to visit the model works recently constructed for bottling the Evian water Here the most ingenious and the latest mechanical devices have been introduced The bottles are washed and cleaned by machinery and it is so arranged that there is no risk of any sort of dust or dirt entering. Once the inside of the bottle has been washed no hand touches the neck until after the bottle has been filled and corked The man who handles the corks wears india rubber and sterilised gloves and is very carefully watched to see that he does not remove these gloves To get such machinery as will prevent all necessity of handling the bottles was a very difficult matter and the present perfection in the process was only attained three years ago Now it is possible to fill 17,000 bottles in a day S on a duplicate set of machines will be obtained and thus it will be easy to double the output By such means it will no longer be necessary to keep the work going through the night as is at present the case during the summer months

The party then returned to the steamer and spent the rest of the afternoon visiting the other and farther end of the lake They passed in front of Montreux, then close under the grey walls of Chillon, duly recalled Byron's homage to Bonnivard, and subsequently saw the arrowy Rhone flow placidly into the lake It was a very enjoyable afternoon On returning to Evian dinner was awaiting and soon afterwards it was necessary to rejoin the special train which had come from Geneva to fetch us A little after eight we started on the uninterrupted run to Paris, which was reached a little before eight the next morning Thus on Wedne day morning, May 17th the party, after spending precisely a week together, finally dispersed

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

The Medical Benevolent Society

THE annual meeting of the above society took place on May 30th under the presidency of Dr E Malins The eighty third annual report was read and adopted The funds of the society now amount to £15,695 19*s* 5*d* 22 annuitants were on the books at the beginning of 1904, two died during the year, one made no further application owing to his improved financial position, and four new annuitants were added The sum disbursed during the year was £797 10*s* , in grants ranging from £20 to £40 In order to meet the heavy demands upon the funds of the society the directors decided to make a reduction of 10 per cent on all annuities This reduction comes into force in 1905 Complaint was made that the society is not supported as it should be by the practitioners of the district for whose benefit the society was originated, that whereas there are about 4000 practitioners in the district there are only 414 benefit members There can be no doubt that considering the good work the society is doing and the quiet help which is given in cases where it is deeply needed the society is deserving of much more general support Dr Arthur S Underhill was elected president for the ensuing year

Birmingham and the Housing Question

A provincial sessional meeting of the Royal Sanitary Institute was held in Birmingham on May 27th to consider the housing question Dr J Robertson, the medical officer of health of the city, read a paper dealing with the problem, in which he recommended the building of workmen's dwellings in suburban areas and the provision of better transit Alderman Cook the chairman of the health committee, was of opinion that the solution of the housing question would mean a reduction in the infantile mortality and a limitation of the spread of tuberculosis Other speakers recommended the institution of a black list containing the names of those tenants who did not observe the ordinary decency of life The German method of buying up belts of land in the surrounding district and laying down the lines on which a city should be developed found many advocates The Birmingham housing committee has decided to send a deputation to Germany to study the method and it is thought that Stuttgart, Frankfort, and Dusseldorf will be visited for this purpose Birmingham has already made a commencement on these lines by the purchase of the Bordesley Green site for workmen's dwellings There is also at present a proposal that Lightwoods Park, which has an area of 18 acres, should be extended to include in all 45 acres, by the acquirement of the historic and picturesque Warley Woods and 12 acres of adjoining pasture land, the latter to serve as playing fields Lightwoods Park being situated in a rapidly growing portion of the city its extension would afford adequate recreation and pleasure grounds for the inhabitants now and in the future The amount required to cover the extension is £13,000 and several donations of £1000 each have already been made

The Proposed Labour Colony

At the last meeting of the conference which was called together to consider Mr Fels s offer of land for a labour colony it was decided that Mr Fels should be thanked for his kind offer and informed that no definite action in the matter could be taken until Parliament has dealt with the Unemployed Workmen s Bill

The Education of the Blind

A new kindergarten school for blind children, the first of the kind in the kingdom, has been opened at Harborne It comprises class rooms, play rooms, dining rooms, dormitories, sick and convalescent wards, cloak rooms and boot rooms, lavatories, bath room, and linen rooms It has been built at a cost of £18,750, of which £15,300 have already been subscribed It is proposed to confine it to children under 12 years of age To show how much could be done in educating the blind it was pointed out that last year 634 persons were benefited, £3351 were paid in wages to blind teachers and workers, and goods were sold to the amount of £8441

The Birmingham Health Committee and Midwives

Four women reported under the Midwives Act by the medical officer of health appeared at the last meeting of the above committee to answer charges of various breaches of the rules of the Central Midwives Board In one case the committee took so serious a view of the matter that it decided to report the woman to the Board In another case the committee suspended for a time the woman concerned , the other two women were severely reprimanded

Hospital News

. Unite of Blackwall Court, bequeathed towards the Birmingham and Midland Hospital for Women Although the hospital is almost rebuilt and will shortly be reopened, and although the money required has been largely subscribed, still much additional equipment will doubtless be necessary from time to time The generous bequest further insures the hospital being opened free from all debt —The Coventry and Warwickshire Hospital is shortly to undergo an extension The existing portion is to be modernised and certain parts are to be demolished The scheme embraces the provision of a new two storey three block building, a new operating theatre, kitchens, stores, mess room nurses' home, an out patient and dispensary department, laundries, mortuary, and isolation block There is to be a new ward pavilion of two storeys, each ward accommodating 24 beds Cross ventilated lobbies and sheltered balconies will also be provided The operating theatre will be equipped with all the latest improvements and will include an x ray and Finsen light room Although the out patients' department will be close to the main hospital the patients will be kept entirely separate from the main block It is estimated that the cost will be £35,000 At the last meeting of the general committee of the hospital a communication was received from the solicitors of the late Mr John Rotherham, for many years senior trustee of the hospital funds, stating that the deceased gentleman had left them a legacy of £1000 A letter was also read from Mr E T Pierson, inclosing a cheque for £50 towards the extension fund "in memoriam of his late son, Captain A E Pierson," and promising a further donation of £100 —The governing body of the Guest Hospital at Dudley has decided to establish an ophthalmic branch and to appoint an additional honorary surgeon

June 13th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Bequests to Medical Charities.

THE trustees of the late Mr. James Holden of Rochdale have made large grants to the following charities: The Rochdale Infirmary, for the Holden Wing, £18,000; the Manchester Children's Hospital, Pendlebury, £10,000; Ashton District Infirmary, £10,000; St. Mary's Hospital, Manchester, £10,000; Stockport Infirmary, £5000; Rochdale Children's Convalescent Homes, St. Anne's-on-Sea, £3000; Rochdale District Nurses' Homes, £5000; and Southport Convalescent Home, £5000. In addition to this large sum of £66,000, Henshaw's Blind Asylum is to receive £10,000; the Children's Sanatoriums at Southport, £1500; and a grant of £5000 is to be made to the Warehousemen and Clerks' Orphanage Home and Schools at Cheadle Hulme. Some other charitable bequests also were, it is understood, made in the will.

Small-pox.

The district is not yet free from small-pox. Two cases were notified to the Oldham sanitary authorities on June 5th. The medical officer at Accrington has reported, however, that that town is now free from the disease. Instead of allowing the small-pox hospital to remain idle he advised that it should be used for cases of advanced consumption, "as the patients would be better nursed and the chances [illegible] would be lessened." The health [illegible] the council to take legal proceedings against a medical gentleman and the father of his patient, for having failed to notify a case of small-pox. This was agreed to.

High Death-rate at Accrington.

The medical officer reported that the death-rate for the year was one of the highest since 1897, while, with the exception of that for the previous year, the birth-rate was the lowest on record.

June 13th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Action against a Medical Man at the Assizes.

AT the recent Liverpool assizes, before Mr. Justice Walton and a special jury, George Hobson, formerly porter at the Royal Liverpool Golf Club, Hoylake, sued Dr. Arthur Bicknell for alleged negligence and breach of duty as a medical man, and for slander. The defendant pleaded that he was not negligent nor was he guilty of any breach of duty; that he never uttered the words alleged; that if he did they were true; and, in the alternative, that they were privileged. Evidence having been given, the judge, in summing up, pointed out that the plaintiff claimed damages under three heads: negligent treatment, breach of confidence, and slander. It was for him (the judge) to say, in regard to the last, whether or not the occasion was privileged, and if it was, and there being no evidence of malice, the jury need not trouble about the claim for slander, except that he would ask them whether or not the plaintiff was suffering as alleged. With reference to the alleged negligence, a mistake was not necessarily negligence. From the expert evidence it appeared that there were often cases in which a medical man could not be absolutely sure of his diagnosis and he might be acting prudently in treating a patient for what it might afterwards be found he had not got. Unless the jury thought that there was not only a mistake but a careless mistake which an ordinary skilful medical man would not make, and ought not to make, they ought not to find Dr. Bicknell guilty of negligence. On the question of breach of confidence his lordship said that apparently the plaintiff told the club steward what the medical man was treating him for and the steward communicated the information to the secretary. Where there was no secret there could be no confidence and he would leave it to the jury to say, having regard to the relations between the plaintiff, the medical man, and the club, whether the defendant had been guilty of a breach of confidence by failing to keep the secret. His lordship put the following questions to the jury, which, after an absence of four hours, they answered as follows: Was there negligence on the part of the defendant in the treatment of the plaintiff?—Yes, inasmuch as he accepted Dr. Moss's diagnosis without sufficient examination, but subsequently he used all reasonable care. Was the plaintiff on August 19th suffering from the disease stated?—No. Was there any breach of confidence by the defendant in telling Mr. Janion that the plaintiff, in his opinion, was suffering from the disease?—No. Did the defendant tell Mrs. Hobson at the interview before Sept. 28th, before the dismissal, that her husband was suffering from the disease?—No. His lordship: You find there was some negligence?—The foreman: Yes. His lordship: Would you tell me what damages the plaintiff has suffered from that? The jury assessed the damages at £71 16*s*., for which amount the judge subsequently entered judgment, with costs, for the plaintiff on the issue of negligence; while, with regard to the slander and breach of duty, he gave judgment for the defendant, with such costs as were attributable to those issues. Notice of appeal has been given and the case will be taken to a higher court.

Runcorn Hospital Extension.

At the monthly meeting of the Runcorn council the health committee reported in regard to the application for a loan of £4000 for hospital extension that the Local Government Board had asked the council to give an undertaking that cases of small-pox would not be treated on the site or within a quarter of a mile of it. The committee had replied, declining to do so on the ground that there would be no place in which to isolate cases of small-pox pending the erection of a small-pox hospital. The Local Government Board had sent a further letter stating that consideration of the council's application would be deferred until the undertaking was given. The committee recommended that a communication should be addressed to the Runcorn rural council to ascertain whether arrangements could be made for a joint small-pox hospital. Mr. Dean, in moving the adoption of the minutes, said the council was not anxious to spend this £4000, as it thought it had ample accommodation. The scheme of extension had been forced on the council and if the Local Government Board did not choose to give it power to borrow the money it would not trouble it. The minutes were approved.

Hospital Saturday Fund: Ladies' Street Collection.

The street collection made by the ladies on Saturday, June 3rd, show [illegible] ff on last year's collection, only [illegible]. The decrease is accounted for by the rapid increase in the workshop and office collections, by the large number of street collections taking place at this period of the year, and by the continued depression in trade.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Diet in Scarlet Fever.

AT a meeting of the Société Médicale des Hôpitaux held on June 2nd M. Dufour read a paper on the subject of Diet in Scarlet Fever, including the suckling of infants. He said that during the present year he had followed a new system in the dieting of scarlet fever patients by allowing them to follow their own inclinations during the first few days (from the third to the sixth day) of the disease without any restriction to particular kinds of food. According to current medical opinion this ought to increase the risk of renal complications, but it had not been followed by albuminuria in the case of any of his patients. Fever is not a contra-indication of feeding a patient. Albuminuria at the outset requires restriction to milk or to a chloride-free dietary and yet there is room for difference of opinion as to the necessity of this, for the resumption of ordinary food on the very day when the albuminuria disappeared was never followed by a return of the symptom. This method of dieting is not of merely theoretical interest but has a useful practical application when a woman has an infant at the breast and the supply of milk has to be kept up. Mothers and infants ought not to be separated in hospital treatment, for this would imply weaning with its attendant disadvantages. Suckling infants appear to be comparatively immune to scarlet fever. M. Dufour believed that solid food might be given without danger to scarlet fever patients from the beginning of the illness if the state of the urine were systematically observed. The results obtained in this way were encouraging, for in 1904 he treated 268 cases of scarlet fever with only four deaths, the mortality being therefore about 1·5 per cent. It ought, moreover, to be remarked that these four deaths were due to extraneous complications, for two of the deceased were greatly addicted to alcohol, one suffered from lead poisoning, and one was a woman who had recently been delivered of a child under very unfavourable conditions. In conclusion M. Dufour said that he could not too strongly recommend bleeding in toxic dyspnœa without renal lesions.

Treatment of Obstinate Facial Neuralgia

At a meeting of the Academy of Medicine held on May 30th Professor Raymond communicated a paper by Dr. Ostwalt relative to the treatment of severe forms of facial neuralgia for which various therapeutic measures had been employed without success. Dr. Ostwalt had made use of his method in about 30 cases, of which 14 had been seen by Professor Raymond or his assistants (*chefs de clinique*), four by M. Marie, and one by M. Dupré. It consists of deep injections of an alcoholic solution of cocaine or stovaine directed towards the principal branches of the trigeminal nerve at their points of issue on a level with the base of the skull. These injections were serviceable not only in facial neuralgia but also in neuralgia of the sciatic, the ulnar, and other nerves.

Miners' Anæmia.

At the same meeting of the Academy of Medicine M. Manouvrier described some new investigations which he had made on miners' anæmia. Like Blanchard, Boycott, and Haldane, [illegible] ible immunity [illegible] wn, is caused [illegible] in the under[illegible] in which there is an infiltration of salt water, such as those of Wieliczka in Galicia, those of St. Just in Cornwall which extends below the sea, and some of those in Anzin adjoining vast subterranean collections of salt water. It has been ascertained that the larvæ of the ankylostomum die in salt water of 1 per cent. strength and these infiltrations often contain as much as 1·8 or 2 per cent. of chloride of sodium. These results have led M. Manouvrier to recommend, if not the addition of salt to the water in mines, at least the use of salt water for sprinkling and for laying the dust which is sometimes a cause of explosions.

June 12th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

An Unusual Case of Hereditary Syphilis.

AT a recent meeting of the Vienna Clinical Society Dr. Hochsinger, director of a dispensary for diseases of children, showed a male patient, 20 years of age, who measured only 110 centimetres (three and a half feet) in height. His genital organs were imperfectly developed, and his face had a drowsy expression on account of paresis of the eyelids. The interesting features of this case were the gradual onset and steady development of symptoms due to congenital syphilis. The father of the patient had contracted syphilis four years previously to his marriage. The patient was the fifth child and the first surviving one. When four weeks old he showed syphilitic symptoms on the skin of the face and legs and in the mucosa nasi. Treatment was continued for only six weeks. In his fifth year he had attacks of paroxysmal hæmoglobin[illegible] liver. Both ailments yi[illegible] mercury. Five years lat[illegible] nerves became paralysed [illegible] After three years he was taken to a hospital on account [illegible] tract and were unlike in size and shape; the knee-jerk was also absent [illegible] present. Infantilism wa[illegible]th, absence of pubic hair, [illegible] the testicles. The disease [illegible] to congenital syphilis. D[illegible] the fact that paroxysmal hæmoglobinuria in children under five years of age was always associated with syphilis.

Radiological Examination of Joints.

Dr. Robinsohn has worked out a method of displaying in [illegible] this purpos[illegible] cautions. [illegible] under cont[illegible]t by the x rays. Radiograms obtained in this way show very clearly, for instance, in the knee-joint the outlines of the supra-patellar bursa, the condyles, the semilunar cartilages, the crucial ligaments, and the alar ligaments. Together with Dr. Werndorff he studied pathological joints in this way and they could distinguish cases of chronic arthritis with a serous effusion without changes in the bone, cases with disease of the synovial membrane, and the [illegible] ures, and chronic degenera[illegible] obliteration of the joint [illegible] e. These latter cases have [illegible] e x rays. The method will [illegible] he Vienna hospitals. It is necessary to have absolutely pure gas and to control the injection of it so that there may be no undue stretching of the tissues.

Vaccination under Red Light.

Dr. Paul, the director of the Vaccine Institute, has published the results of a series of experiments conducted with the view of ascertaining the value or otherwise of red light in vaccination. As vaccination is compulsory and gratuitous and as the above-mentioned State institute supplies all the material used the director was able to control the results. A room was specially fitted up for this purpose with red glass in the windows and the inoculation wounds were bandaged with red calico. It may here be mentioned that some vaccinators prefer the French method of vaccinating on the upper part of the thigh, thus avoiding scars on the arm, a point worth consideration amongst the better classes on account of the low dresses worn by ladies at balls, theatres, and the like. The results obtained under red light differed materially from those of ordinary vaccination. The pain and itching were sometimes less, the accompanying inflammation was certainly less marked, and lymphangitis was not very often seen. But the effect was most obvious in the formation of the scar which was very satisfactory from the cosmetic standpoint. In consequence of Dr. Paul's observations quite a number of practitioners in the country have followed his example and are sending in their observations to be used for statistics.

The Yearly Report of the Polyclinic.

The Vienna Polyclinic, the medical institution next in importance for teaching after the General Hospital, has just held its annual meeting, at which the director, Professor Monti, read the report for 1904. The number of in-patients amounted to 3208, comprising surgical, internal, pædiatric, and gynæcological cases. There were 689 major and 152 minor operations performed in the different wards. A new feature was the admission of 882 infants, a comparatively large number which was accounted for by the coöperation of the Polyclinic with the newly formed society for distributing milk to infants. The mortality from diphtheria was 3·89 per cent., being the lowest on record since the introduction of Behring's serum. The mortality from all diseases was 6 per cent., the proportion of recoveries was 82 per cent., and that of cases incurable or becoming worse was 12 per cent. The expenditure per patient per day was about three kronen, equal to 2*s.* 6*d.* The institute, which is under private ownership and management but coöperates with the University, inasmuch as the professors lecture for State students, is now self-supporting, and its income has even a tendency to increase. Amongst the members of the staff there are some very celebrated teachers, such as Professor Monti, Professor Urbantschitsch, and Professor Spiegler.

Radium in Mineral Waters.

M. P. Curie and M. Laborde discovered comparatively large quantities of radium emanation in the mineral waters of Gastein and [illegible] waters from the [illegible] effects which th[illegible] from the spring [illegible] found that all these materials were capable of stopping the development of the bacillus, especially the sediment, which actually had the strongest germicidal effects, killing the bacillus within a few hours. Mineral water bottled for longer than 48 hours had no effect whatever, not differing, in fact, from ordinary water. Dr. Kallmann therefore asserted at the meeting of the Graz Medical Society, where he read his paper, that the beneficial results of bathing in Gastein water are easily explained by the presence of a quickly evanescent radium constituent in the water.

June 12th.

NEW YORK.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Department of the St. Louis Exposition.

THE late Universal Exposition, held at St. Louis, Missouri, had a well organised medical department, the medical director of which has submitted his report. The duties of the department were to have jurisdiction over all cases of personal injury; to assume the care of the resident population and visitors and of such other cases as the Exposition Company might be responsible for, or which in their judgment should be cared for; and to exercise a supervision over all sanitary and hygienic matters connected with the grounds and buildings and over all matters pertaining to the health and physical well-being of the employés engaged in the conduct of the exposition. The officers of the department consisted of a medical director, five attending surgeons, one visiting physician, one bacteriologist, one sanitary officer, three ambulance surgeons, one sanitary expert, and one sanitary inspector. A permanent emergency hospital was erected, complete in all its appointments, for the accommodation of officers, nurses, and attendants and equipped with the most improved appliances. The total number of cases treated during the entire period was 29,045. There were 7 births and 40 deaths, of which 23 were from violence and 17 from natural causes. A number of workmen escaped fatal results in falling 50 feet or more and one was uninjured by a fall of 120 feet. There was but one fatal case of gunshot injury. During the exposition beri-beri appeared and there were 45 cases and 3 deaths The disease occurred among the tribe of Igorotes from the Philippine Islands.

The Department of Sanitation at the Isthmus of Panama.

The recent outbreak of yellow fever at Panama indicates that the rumours of defects in the measures taken to prevent that disease were too true. No one doubts the ability of Colonel Gorgas, the head of the sanitary service, to employ preventive measures to the best possible advantage, but there have been rumours that the commission has refused to allow many important requests which he has made, and that on this account the fever has gained a foothold which it could not have done had he had a free hand from the first. The new commission recently met at Washington and perfected the organisation of the department of sanitation on a scale commensurate with its importance. The salary of the chief sanitary officer has been fixed at $10,000, of the director of hospitals at $8000, of the chief quarantine officer at $7000, and the other officers have salaries according to their grade. In addition to the hospital at Ancon and at Colon the commission ordered the erection of another hospital at Colon at a cost of $40,000. The latest reports show that of the 7000 employés on the canal 350 are in hospital, or about 5 per cent.

Abolition of State Boards of Health.

There is a growing tendency in this country to abolish the State boards of health and substitute for them a health officer, or, as he is more often called, a commissioner of health. In the State of New York the substitution was made two years ago, a large and well organised board being summarily abolished and in its place a single general practitioner placed by appointment of the Governor. Now the State of Pennsylvania has followed the example and abolished its board of health and appointed a commissioner of health in its place. This change is in the interests of partisan politics and is destructive of the first principles of efficient sanitary administration. The true functions of the department of sanitation in a Government are the creation and enforcement of sanitary ordinances which have the force and sanctity of law. It should, therefore, have as its head a body having both legislative and administrative powers, an organisation that cannot exist when there is but a single official at its head. In the State of New York this change in the character of the head of the department has been followed by a distinct loss of prestige of that service and a marked deterioration in its power and efficiency. The United States has been developing a most complete and efficient system of sanitary administration, extending from the hamlet and municipality through the State Governments to the National Government. This recent change of the State boards is destined to work great harm by impairing the proper coördination of functions of the several parts of the system and on that account is greatly regretted by sanitary legislators. In this State the Governor has recently appointed a homœopathic physician to the position of commissioner of health, the effect of which will be to alienate the interest of the regular profession entirely from the department.

A Protest against Quarantining Cuba.

No single event in the history of municipal sanitation more strikingly illustrates the value of modern methods than the improvement in the public health of the cities of Cuba. Previously to the occupation of the island by the United States quarantines were early established, at all the Atlantic and Gulf sea ports, against Cuba and were rigidly maintained until very late in the season. Now such action on the part of the cities of the United States is promptly resented by the Cuban health authorities. The State health boards of the Gulf States recently issued a quarantine order against passengers from cities of Cuba other than Havana. As soon as this action became known in Cuba the Cuban national board of health sent a cable message to the Louisiana State board of health to the effect that the superior board of health protests against their action discriminating against territory of the Republic outside of Havana, and alleging that they are in constant touch with all districts, and they know that these districts are just as free from all quarantinable diseases as is Havana. Dr. Finlay, chief sanitary officer of Cuba, says that there is no justification for this discrimination against the island outside of Havana, for the entire country is under constant and effective control. When a case or a suspected case of a quarantinable disease occurs anywhere in Cuba the local officer is compelled to telegraph the fact at once to the chief sanitary officer at Havana. The latter then orders the provincial inspector of the corresponding province to investigate the case. The inspector telegraphs the result of his investigation; if the diagnosis is confirmed or the suspicions are maintained one or more experts are sent and every measure is taken to prevent the spread of the disease.

Prevention of Tuberculosis.

The first annual meeting of the United States National Association for the Study and Prevention of Tuberculosis commenced in Washington on May 18th; Dr. William Osler, vice-president of the association, delivered an eloquent address. He emphasised the need of educating the public with regard to tuberculosis. He said: "Education regarding tuberculosis is the thing to strive for. The public is awake but sitting on the edge of the bed and not yet dressed. In this awakening, however, much has been accomplished over past conditions. When the public gets dressed much activity will follow and much will be accomplished towards stamping out the disease." Dr. Osler also said that no greater mistake was possible in the treatment of tuberculosis than to keep from the patient in the early stages of the disease the full knowledge of its existence. Dr. Herman M. Biggs, chief medical officer of the New York board of health, laid especial stress upon the good results of compulsory notification. He showed what had been accomplished by these means in New York city which was still the only great city where it was practised. The discussion on May 19th brought out the fact that all efforts so far to establish self-supporting communities or settlements of tuberculous patients had proved a failure. The opinion was general that all cases of tuberculosis should be allowed to remain at large where proper care of the patient was maintained and proper sanitary requirements observed to protect members of the family in the house of which the patient resided. In November the first American tuberculosis exhibition will be held in New York city. It will be organised under the auspices of the United States National Association for the Study and Prevention of Tuberculosis and the committee for the prevention of tuberculosis of the New York Charity Organisation Society. Dr. Ernst J. Lederle, former commissioner of health of New York city, is chairman of the committee in charge.

June 3rd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

BUBONIC plague is spreading in New South Wales and Queensland. Cases have occurred in Sydney, Newcastle, Brisbane, and Ipswich, and the area from which they come and in which plague-infected rats have been found is extending. Several of the cases have proved fatal. Plague-infected rats are still found in the Richmond River district. Plague first appeared in Newcastle on March 27th and since then six cases have occurred, two fatal. One of the victims was a medical man, Dr. J. R. Leslie, who had been attending a plague patient and assisted at a post-mortem examination of his body. Dr. Leslie is a young graduate of the University of Sydney who succeeded to the practice of Dr. Andrew Nash who died in March last from blood poisoning. Dr. Leslie is improving. The Newcastle municipal council held a special meeting to deal with matters affecting public health. The model by-laws, drafted by the Board of Health as a means of helping to deal with bubonic plague, were adopted. House-to-house inspections were being made. At Ipswich in Queensland five cases of plague were reported in one day and sent to the Colmslie plague hospital.

Dengue Fever.

Dengue fever is still very prevalent in Brisbane. The sittings of the district court had to be postponed owing to the illness of the judges. The drain on the funds of the friendly societies for sick pay is becoming severely felt. A case of dengue has occurred at Wagga in New South Wales. A peculiar feature of some of the cases in Brisbane has been a tendency to somnolence for two or three days. In other cases the want of sleep has brought on mental conditions necessitating removal of patients to the reception house

Hospital Affairs.

There are two distinct institutions in Sydney for the treatment of women—viz., the Women's Hospital and the Royal Hospital for Women. The latter is conducted by the Benevolent Society of New South Wales. For about 87 years this body endeavoured to treat women in labour and gynæcological cases in an ancient building erected by Governor Macquarie. Here it also gave outdoor relief and cared for infants. This site and building were resumed by the Government for the new central railway station. With the funds, £62,000, given as compensation, the society has established two separate institutions—viz., a receiving house at Ultimo, with accommodation for infants and to provide for the administration of outdoor relief, which is now in full working order, and a separate hospital at Paddington, which was formally opened by Her Excellency Lady Northcote on May 3rd. The building erected is only a wing of the future hospital. It is thoroughly up to date and will provide 100 beds and the operating block.—The annual meeting of the subscribers to the Queen Victoria Homes for Consumptives was held on April 13th. The fund started with £1100 more to its credit than last year and the upkeep of the two homes was £3297 as against £3699 the previous year. Accommodation for 85 cases was now available.—It was formally announced some time ago that the Government institution at Broadmeadows, Victoria, for the treatment of consumptives would be opened on May 1st but it is not yet ready. Dr. Drake has been appointed medical superintendent. The buildings erected are eight tents for patients, quarters for the medical superintendent and matron, dining-hall, kitchen, and rooms for domestics. The tents each contain six beds. The cost so far is £2000. The water-supply has still to be arranged. For incurable cases nothing has been done, and the Kronheimer wing at the Austin Hospital is not yet opened. It was thought that some agreement had been arranged but the Premier subsequently altered the conditions in which he would permit the new wing to be opened and nothing was done.—The Melbourne Hospital will shortly have been erected 50 years. In view of this fact the committee has decided to ask the Governor General to request His Majesty the King for permission to call the institution the Royal Melbourne Hospital

Amputation under Spinal Anæsthesia with Eucaine.

In the *Intercolonial Medical Journal* for April Mr. J. Ramsay records a case of amputation for gangrene under anæsthesia produced by injection into the spinal canal of 50 minims of 1 per cent. solution of β eucaine in normal saline solution. In five minutes total analgesia of the lower extremities was produced and the limb was painlessly amputated at the knee-joint. Sensation returned in two and a half hours. The evening temperature reached 101·2° F. and the patient had hiccough and flatulence. He had no headache or vomiting. On the next morning his temperature was normal. Recovery was uninterrupted. The patient was considered unsuitable for a general anæsthetic, having a dilated heart, loud bruit, atheromatous vessels, and a large amount of sugar in the urine.

Case of Abdominal Pregnancy.

In the same journal Dr. F. Meyer records a case of what he regards as primary abdominal pregnancy. Both tubes were normal and intact, and the placenta was attached to the posterior surface of the uterus.

Obituary.

Dr. Thomas Cole Wright, who had been practising at Gulgong, New South Wales, for some years, died suddenly from cerebral hæmorrhage. He had apparently been in perfect health previously.

May 8th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations, have been admitted Members of the College and have received their diplomas :—

[illegible] ; Frank Anderson Juler, [illegible] and St. Mary's Hos- [illegible] y's Hospital ; Frederick [illegible] y and St. Bartholomew's [illegible] Durham University and University College, Cardiff, [illegible], London Hospital; [illegible] and Royal Infirmary, Man- [illegible] S. Eng., Mason College and [illegible] homas William [illegible], [illegible] ital; Harold Philip Martin, [illegible] oronto, and Middlesex Hos- [illegible] ls, and Basil Eustace Moss, [illegible] m Miles, St. Mary's and Middlesex Hospitals; Percy Frank [illegible] inett and Arthur Boniface [illegible] Richard-Parkinson, [illegible] Hospital; Percival [illegible] College Hospital; [illegible] Royal Infirmary, [illegible] Robert Elliot Pitts, [illegible] Christopher Pounds and Arthur [illegible] le, Charing Cross Hospital; George [illegible] and St. Thomas's Hospital; James [illegible] x Hospital, Owens College, and Royal Infirmary, Manchester; Percy George Reilly, Robert Leslie Ridge, and George Fitzgerald Rudkin, London Hospital; Frank Melville Pitcairn Rice, Horace Hammond Rolfe, and Harold Edward Scoones, St. Bartholomew's Hospital; David Harold Richards, Guy's Hospital; John Chambers Lawton Roberts, Cambridge University and St. Thomas's Hospital; James Edmund Rutherford, Oxford University and St. George's Hospital; Emil Schwarz, Vienna University and Charing Cross Hospital; William Lochhead Scott, University College Hospital; Harold Munro Scott, London Hospital; Timothy William Sexton and Armstrong Smith, Middlesex Hospital; Cyril Aubrey Smallhorn, Oxford University and St. Bartholomew's Hospital; Thomas Stordy Charing Cross Hospital; Samuel Henry Sweet, University College, Cardiff, and London Hospital; A [illegible] versity College, Liverpool, and Universi [illegible] Edwin Charles Tatam, L.S.A. Lond., Ki [illegible] George Thom, King's College Hospital; [illegible] Guy's Hospital; Louis Clifford Thompson, [illegible] Bristol, and University College Hospital; Arthur Toulmin, Owens College and Royal Infirmary, Manchester; William Samson Tresawna, Cambridge University and St. George's Hospital; John Ronald Rigden Trist, Frank Edred Whitehead, and Augustus Scott Williams, St. Bartholomew's Hospital; Rawdon Augustus Veale, Yorkshire College and General Infirmary, Leeds; William Charles Augustus Ward and David Wilson, St. Thomas's Hospital, Walter John Weston, St. George's Hospital; Alfred Garth Whitaker, Charing Cross Hospital, William Percival Gould Williams, Cambridge University and St. Thomas's Hospital, and Ernest Douglass Welff, King's College Hospital.

The following gentlemen passed the first professional examination for the diploma of Fellow at the quarterly meeting of the examiners.—

James Johnston Abraham, M.B. Dub., Dublin, King's College, St. Bartholomew's and London Hospital; David Macrae Aitken, M.B. & F.R.C.S. Edin., Edinburgh University; David Thomas Barry, M.D., R.U.I., D.P.H., Queen's College, Cork, and Liverpool University; Thomas Herbert Cecil Benians, London Hospital; Wilfred Edward Brierley, M.B. Vict., Yorkshire College, Leeds, and King's College, London; Colin Clarke, St. Bartholomew's Hospital; Alfred John Couzens, London Hospital; Kenelm Hutchinson Digby, Guy's Hospital; Reginald Lionel Ernest Downer, St. Bartholomew's Hospital; George Greig Farquhar, M.B., Ch.B., Aberdeen University and London Hospital; William Stephen Fenwick, Charing Cross Hospital; Charles William Greene, B.A. Cantab., Guy's Hospital; Edgar Hartley Kettle, [illegible] Cantab., [illegible] Mary's [illegible] lomew's [illegible] gham; [illegible] sity and [illegible], M.B., [illegible] William [illegible] Henry Lewis Morgan, London Hospital; William Maxwell [illegible], M.B., Ch.B. Edin., Edinburgh University and London Hospital; Humphrey Nockolds, University and King's College, London; Charles Aubrey Pannett, B.Sc., St. Mary's Hospital; Robert Nuttall Porter, M.D., Ch.B., Owens College, Manchester; Harold Vernon Prynne, Middlesex Hospital; Harry Richardson Rawlings, University of Leeds; Rupert Lewis Rawlinson, B.A. Cantab., Cambridge University and King's College, London; James Ernest Helme Roberts, St. Bartholomew's Hospital; David Robertson, Edinburgh University; Alfred Basil Rooke, University [illegible] nald Whatley Roy, B.A. Cantab., S [illegible] bert Frank Shorney, M.D., B.S. Melb., [illegible] Middlesex Hospital; Walter Stansfield, Owens College, Manchester; Leonard Smith Talbot, M.B., Ch.B. New Zealand, King's College, London, and Otago Medical School, New Zealand; Henry Darby Thomas, London Hospital; Reginald Stephen Townsend, St. Bartholomew's Hospital; Harold Fitz-Vellacott, London Hospital; John Walker, St. Thomas's Hospital; Harry Gordon Webb, St. George's Hospital; and Carl Ernest Zunde, London Hospital.

122 candidates presented themselves, of whom 40 passed and 82 were referred. Of the 82 candidates who were referred, 42 failed to reach the required standard in both Anatomy and Physiology, 23 in Anatomy only, and 17 in Physiology only.

The following gentlemen having passed the necessary examination and having conformed to the by-laws and regulations have been admitted Fellows of the College in order of seniority as Members of the College:—

Frank Arthur Spreat, L.S.A. and D.P.H. Lond., St. Bartholomew's Hospital, Member July 30th, 1884; Frec [illegible] D.P.H., L.R.C.P. Lond., St. Barthol [illegible] April 28th, 1886; William Selby, D.S. [illegible] Lond., St. Bartholomew's Hospital [illegible] Thomas Howard Foulkes, Capt. I.M.S., L.R.C.P. Lond., St. Bartholomew's Hospital, Member Nov. 10th, 1892; James Midleton Graham Sw [illegible] August 4th [illegible] and London [illegible] M.B., D.P. [illegible] pitals, Mem [illegible] Lond., Guy's and London Hospital, Member July 27th 1899; Robert [illegible] Smith, M.A., M.B., B.Ch. Oxon., L.R.C.P. Lond., St. George's Hospital and Oxford University, Member Feb. 13th, 1902; Owen William Richards, M.D., B.Ch. Oxon., L.R.C.P. Lond., Oxford University and Guy's Hospital, Member May 8th, 1902; Harry Pierpoint, L.R.C.P. Lond., University College, Liverpool, Member July 31st, 1902; Bernard Joseph Ward, L.R.C.P. Lond., Birmingham University and London Hospital, Member July 31st, 1902; Moses Thomas Williams, M.B., L.R.C.P. Lond., London Hospital, Member July 31st, 1902; William Warwick James, L.R.C.P. Lond., L.D.S. Eng., Middlesex Hospital, Member Nov. 13th, 1902; Oliver Francis Haynes Atkey, M.B. Lond., King's College Hospital, Member Feb. 12th, 1903; Walter Leigh Mackinnon Goldie, L.R.C.P. Lond., Edinburgh University and St. Mary's Hospital, Member Feb. 12th, 1903; Thomas Guthrie, M.A., M.B., B.C. Cantab., L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital, Member Feb. 12th, 1903; Arthur Francis Hamilton, M.D. Lond., L.R.C.P. Lond., St. Bartholomew's Hospital, Member Feb. 12th, 1903; Henry Bailey Mylvaganam, L.R.C.P. Lond., St. Bartholomew's Hospital and Ceylon Medical College, Member Feb. 12th, 1903; Francis Seymour Kidd, M.B. Cantab., L.R.C.P. Lond., Cambridge University and London Hospital, Member May 14th, 1903; Leonard Noon, B.C. Cantab., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital, Member August 4th, 1903; James Douglas Cooke, M.B., B.S. Melb., L.R.C.P. Lond., Melbourne University and London Hospital, Member Nov. 12th, 1903; Arthur Cyril Hudson, M.A., M.B., B.C. Cantab., L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital, Member May 12th, 1904; Frederic William Daniels, L.R.C.P. Lond., London Hospital, Member July 28th, 1904; Tom Bates, L.R.C.P. Lond., St. Bartholomew's Hospital, Member Nov. 10th, 1904; Thomas Bonhôte Henderson, M.A., M.B. Oxon., L.R.C.P. Lond., Oxford University and St. Thomas's Hospital, Member Nov. 10th, 1904; Sydney Chalmers Allen, M.D., B.Sc. New Zealand, L.R.C.P. Lond., New Zealand University and London Hospital, Member May 11th, 1905, John Dun [illegible] Queen's College, Cork, not a member; [illegible] B., Ch.B. Aberd., Aberdeen University, [illegible] d King's College Hospital, not a member; Edgar Montague Pilcher, D.S.O., Major R.A.M.C., M.B., B.Ch. Cantab., Guy's Hospital, not a member.

UNIVERSITY OF CAMBRIDGE.—Dr. G. C. Low, superintendent of the London School of Tropical Medicine, has been appointed an examiner for the Diploma in Tropical Medicine and Hygiene in the place of Sir Patrick Manson who is unable to examine in August.—Dr. D. MacAlister has been re-appointed assessor to the Regius professor of physic.—At the Congregation on June 8th the following degrees were conferred:—

M.D.—F. A. S. Hutchinson, Trinity; J. W. Rob, St. John's; A. de W. Snowden, Christ's; and J. E. Molson and H. S. Willson, Emmanuel.

D.Sc.—Professor W. R. Sorley.

M.B.—H. H. Clarke and S. M. Mackenzie, Trinity; R. N. Poignand, Caius; J. A. A. Orlebar, Magdalene; and H. Wales, Sidney Sussex.

B.C.—S. M. Mackenzie, Trinity; R. N. Poignand, Caius; and J. A. A. Orlebar, Magdalene.

UNIVERSITY OF OXFORD.—The following scholarships are announced in natural science: June 20th, St. John's College; July 4th, Brasenose College; and Dec. 12th, University, Lincoln, and Magdalen Colleges.—Walter W. W. Fisher, M.A., Corpus Christi College, Aldrichian Demonstrator in Chemistry, has been appointed an examiner in preventive medicine for the examinations in 1905, 1906, and 1907.

THE ANNUAL DINNER OF THE CHELSEA CLINICAL SOCIETY.—Dr. T. Vincent Dickinson, the President, took the chair on June 8th at this dinner, which was held at the Criterion Restaurant, London. A large number of the members of the society and their friends attended and the proceedings were marked by much enthusiasm. The first speaker after the loyal toasts had been honoured was the President who proposed "The Chelsea Clinical Society." He commented with great satisfaction on the speech lately delivered by Sir Richard Douglas Powell in which that gentleman declared that the scheme for the amalgamation of the various medical societies in London was not intended to include local societies like the Chelsea Clinical Society. Sir Douglas Powell stated definitely that it would be a distinct loss if such local societies ceased to exist. Dr. J. Barry Ball was intrusted with the reply to this toast and after some music had been well rendered Mr. E. Noble Smith proposed "The Visitors and Kindred Societies." This was suitably replied to by Mr. W. Arbuthnot Lane and the Rev. Dr. Collison. More music and songs followed and an enjoyable evening was terminated by Dr. Seymour Taylor submitting the toast of "The President and Officers of the Society," which was acknowledged by the President.

ST. PETERSBURG CHILDREN'S HOSPITAL.—The opening of the St. Petersburg Town Children's Hospital, built in honour of the coronation of their Imperial Majesties the Russian Emperor and Empress, has taken place recently. The hospital consists of 18 separate buildings and contains 400 beds. The staff in permanent residence on the premises numbers 250. The cost of the institution amounts to about £170,000.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—The annual general meeting of this [illegible] [illegible]esday, June 27th, at the [illegible] [illegible] M. At 7.30 the members [illegible], Surgeon-General G. J. H. Evatt, C.B., the President-elect, being in the chair. Any Poor-law medical officer desiring to be present should communicate with Dr. Major Greenwood, honorary secretary, 9, Copthall-avenue, London Wall, E.C.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—At the annual meeting on June 1st Dr A. Newsholme was elected President for the ensuing year: Mr. G. Morgan and Dr. F. J. Paley Vice-Presidents; Mr. O. J. Oldham treasurer; Dr. R. Sanderson honorary librarian; and Dr. E. Hobhouse and Dr. Walter Broadbent honorary secretaries. Mr. W. A. Bowring, Mr. A. H. Buck, Dr. W. C. Chaffey, Dr. F. Hinds, Dr. L. A. Parry, Dr. J. W. Pugh, Dr R. J. Ryle, and Mr. T. J. Verrall were elected members of the council.

CHÂTEL-GUYON AND MEDICAL MOTORISTS.—On account of the advantageous position of Châtel-Guyon as a starting point for excursions in Auvergne, as well as its proximity to the "*circuit*," the local Syndicat Médical offers various facilities to medical men who wish to be present either at the trial matches (*éliminatoires*) or at the "*coupe*." These facilities include a claim to a certain number of rooms in the best hotels, reserved garages, and seats in the tribune of the Société Sportive Riom-Châtel-Guyon. Application should be previously made to the Président du Syndicat Médical de Châtel-Guyon-les-Bains, Puy-de-Dôme, France.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—The annual meeting of this association was held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, on June 9th, under the presidency of Dr. J. W. Hembrough of Newcastle-on-Tyne. There was a good attendance. The annual report and balance-sheet of the treasurer showed that the numerical strength of the association is steadily increasing and that its financial condition is highly satisfactory. The question of taking steps to obtain Parliamentary representation for the University was again brought forward and the result of the recent appeal made to the Senate on this subject was discussed. In view of the advanced stage of the session it was decided to postpone further action in the matter for the present. General regret was expressed at the retirement of Dr. T. Outterson Wood from the post of honorary secretary for the South and a resolution acknowledging the excellent work which he had done for some years in that capacity was unanimously passed. The following were elected as the officers and council for the year 1905-06. President: Dr. Herbert T. Herring. Vice-Presidents: Dr. Selby W. Plummer and Dr. C W Chapman. Council: Mr. H. B. Angus, Dr. John Clay, Dr. H. Smith, Dr. William Martin, Dr. T. Beattie, Dr. E. W. Diver, Dr John Cahill, Dr. F. H. Carter, Dr. F. E. Green, Dr. William Rawes, Dr. W. J. Hadley, and Dr. R. J. Probyn-Williams Honorary secretaries: Dr. J. W. Leech for the North and Dr. F. S. Pal[illegible] [illegible]reasurer Dr R. A Bolam. [illegible] T. M. Allison, and Dr. H. Sn[illegible] Dr. W. C. Beatley, Dr. M. Mitchell Bird, Dr. H. T. Herring, and Dr. S. W. Plummer. The members and guests (numbering 84) dined together in the evening at the Imperial Restaurant, Regent-street. Dr. Herring, the newly elected president, occupied the chair. After the usual loyal toasts had been given that of the University of Durham and its Medical Graduates' Association was proposed by Mr. Christopher Heath and responded to by Sir George Hare Philipson and Dr. Palmer. The toast of the visitors was proposed by Dr. Plummer and replied to by Sir Lauder Brunton. Dr G. A. Heron proposed the health of the President and Dr. Herring replied. Excellent music was provided under the direction of Mr. Arthur Godfrey and a most enjoyable evening was spent.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—The general meeting of this society was held at 20, Hanover-square, London, W., on May 31st, Dr. F. Bagshawe (St. Leonards) being in the chair.—The officers and council for the ensuing session were elected, Dr. G. W. Hamilton Cumming (Torquay) being chosen as president. Dr. William Murray (Newcastle-upon-Tyne) was unable to be present owing to an accident, but his address, entitled "The Limitations of Treatment," was read by Dr. Leonard Williams and was much appreciated by the Fellows. The address will be published in the *Journal of Balneology and Climatology*. Dr. E. Symes-Thompson proposed, and Dr. Bagshawe seconded, a vote of thanks to Dr. Murray, which was carried unanimously. On the same evening the annual dinner of the society was held at the Criterion Restaurant.

THE FERNLEY [illegible] on the work of the [illegible] at Southport for the ye[illegible] [illegible]ro-logist to the Southport corporation, states that the weather at that place during the year was very dry but, on the whole, sunless, with much fog and haze. There was no strikingly hot or cold month. The total duration of bright sunshine was *1473·5 hours, being 92·6 hours below the average, and* the total rainfall was 26·01 inches, or 7·41 inches below the average; in London for the same period the total duration of bright sunshine was 1327·6 hours. The mean amount of atmospheric ozone at the Fernley Observatory was less than in any previous year since it was established in 1871. The lowest temperature registered on the grass by a sensitive terrestrial radiation minimum thermometer was 13·4° F. on Feb. 29th. The greatest general thickness of the ice over the large lake in Hesketh Park was 1·7 inches on Nov. 27th. During the autumn and winter season the observatory was opened to the general public on three evenings weekly and celestial objects were viewed through the six-inch refracting telescope by 168 visitors.

WEST LONDON HOSPITAL AND POST-GRADUATE COLLEGE: ANNUAL DINNER.—Under the genial chairmanship [illegible] present students of the [illegible] London Hospital held thei[illegible] [illegible]staurant, London, on June 7th. The guests present included Sir R. Douglas Powell, Director-General H M. Ellis, Royal Navy Medical Service, Director-General A. H Keogh, Army Medical Service, and Mr G F. Marshall, member of the board of management of the West London Hospital. The loyal toasts having been duly honoured Mr. C. B. Keetley in an amusing speech proposed the toast of "The Imperial Forces" which was responded to by Director-General Ellis, who said that the Royal Navy Medical Service owed a deep debt of gratitude to the West London Hospital. A very considerable number of naval medical men had undergone their post-graduate course in that hospital. Director-General Keogh, who also replied to the toast, explained how arrangements had been made for the officers of the Army Medical Service to receive instruction in London. He, however, particularly addressed himself to the question of the position of the volunteer medical officer. In case of war the Director-General of the Army Medical Service would be the only officer of that service left in this country, the volunteer medical officers supplying the places of those who would have gone abroad. It was not sufficient for a medical officer to be able to take care of a regiment. What had to be done was to provide an organisation to take the place of the Army Medical Service in the case of need and he invited the attention of those who were interested in the post graduate movement to the necessity of something being done in that direction. The Chairman proposed the toast of "The West London Hospital and Post-Graduate College" and congratulated those present on the success of the institution. The Dean, Mr. L. A. [illegible] gave some interesting [illegible] the college. He con[illegible] it was that the college [illegible] adequate for the purposes which buildings should be made they were intended to serve. The toast of "The Visitors" was proposed by Mr. F. Swinford Edwards and was responded to by Sir R. Douglas Powell who observed how the wants of post-graduates were admirably met by the West London Hospital. After the toast of "The Chairman" had been duly submitted and suitably replied to the proceedings came to an end.

Insanitary Conditions in Bolivia.—Writing from Oruro, the chief mining district of the Bolivian Republic in South America, Mr. J. Ramsay Smith, British Vice-Consul, observes that miners are scarce and wages have doubled in the last few years. The pure-bred Indian does not work in the mines as a rule but lives on his small patch of land or brings native fuel, &c., on his llamas and donkeys for the mining establishments. The half-breed is the labourer of the country. During the present boom all kinds of labour-saving machinery and appliances have been introduced to render the work as automatic as possible but much remains to be done in this line. The climate of the district is good—a dry, bracing mountain climate—but mortality is very high (about 100 per 1000). Intemperance is general amongst the working classes. They are not particular about the quality of the drink provided it be alcoholic. Their food depends on themselves. Fresh beef, mutton, good bread, and potatoes are usually abundant and cheap. Their houses are mere hovels without windows or ventilation. Modern ideas of sanitation are nowhere practised. Drainage of the towns does not exist. In the yard of most houses there is a deep pit into which all the excrement is thrown without the addition of any disinfectant. It is not to be wondered at that typhoid fever, small-pox, and the exanthematous fevers are endemic and make frightful ravages in the population every year. However, the local authorities and the medical profession are at length taking some steps to remedy this. They propose to have an infectious diseases hospital, for example.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Sir John Batty Tuke and the Scotch Education Bill.

It is doubtful whether there will be time to carry the Scotch Education Bill through the committee stage, but should the necessary facilities be provided Sir John Batty Tuke will propose several amendments of medical interest. Two of these proposals may be quoted. One reads thus: "The school board of every district may, or where required by the education department shall, provide for the medical examination and supervision of the pupils attending schools under their charge to such extent and subject to such requirements as may from time to time be prescribed by any code or minute of the department, and, for the purposes of this section, the school board may appoint such medical inspectors, to be approved by the department, as may be necessary, or may arrange with any local authority acting under the Public Health (Scotland) Act, or with a medical corporation, or with any person or body of persons approved by the department, to conduct the examination and supervision on their behalf." Another is as follows: "The medical officer of health, or any medical officer duly authorised by the local authority for that purpose, may, *with the consent of the school board or board of managers of any* public or State-aided elementary school within the district, enter such school under the control of such school board or board of managers and if on examination he shall be of opinion that the person or clothing of any child attending such school is infected with vermin or is in a foul or filthy condition so as to be prejudicial to health he shall give notice in writing to the parent or guardian or other person who is liable to maintain or has the actual custody of such child requiring such parent, guardian, or other person to properly cleanse the person and clothing of such child within 24 hours after receipt of such notice. The local authority or the school board or the board of managers may give the use, free of charge, of any place or apparatus which the local authority or the school board or the board of managers possess for cleansing the person or clothing of such child. If the person to whom such notice is given fails to comply therewith within the prescribed time *the medical officer of health or* medical officer duly authorised as aforesaid shall cause the person and clothing of such child to be properly cleansed and, if necessary for that purpose, may instruct an officer of the local authority, without any warrant other than a certificate from the medical officer of health or medical officer aforesaid, to convey to a suitable place and therein detain such child until such cleansing is effected: always provided that in the case of a female child only a female officer shall be authorised to convey and detain the child for the purpose of cleansing. Any expenses incurred in carrying into effect the provisions of this section may be defrayed out of the public health general assessment. The school board or board of managers of any public or State aided elementary school may refuse to admit into any school under their control any child who shall be certified by the medical officer of health *or any medical officer acting* under the authority of this Act to be suffering from a contagious skin disorder, and the parent or guardian of any child so suffering who shall fail forthwith, on intimation in writing from the school board, to procure medical advice and treatment for such child shall be liable to a penalty not exceeding 10*s*. for every day during which he makes default."

HOUSE OF COMMONS.

Wednesday, June 7th.

The Plague in India.

Mr. Field asked the Secretary of State for India whether he was aware that in India in 1901 the total deaths from plague were returned at 273,679, in 1902 the number rose to 577,427, in 1903 it reached 851,263, and in 1904 it was 1,022,299; and what steps were taken by the Government for the prevention of the spread of plague.—Mr. Brodrick answered: I am aware of the lamentable mortality from plague indicated by the figures quoted by the honourable Member. The Government is endeavouring, while necessarily respecting the feelings and the prejudices of the people, to assist them by every possible means to help themselves and to bring within their reach all material means to that end. It is promoting, in the matter of prevention, the more efficient sanitation and cleansing of towns and villages, the destruction of rats and mice, and the means of inoculation. It is enlisting and organising unofficial help by the formation of health and charitable committees, and has defined the duties of municipalities and other similar bodies in respect of giving intelligence, of providing hospitals and free sites for camps, and of succouring homeless wayfarers. On the occasion of any outbreak of plague it encourages and, through its medical and administrative officers, assists the residents to disinfect their houses and property, to isolate the sick, to destroy infected materials, and to evacuate plague stricken dwellings and sites. It gives compensation for loss of property to the poor and assists them to rehouse themselves It maintains laboratories for the preparation of fluid for inoculation and for the systematic study and diagnosis of the disease; and it has placed at the disposal of an *advisory committee of* the highest authority in this country a grant of money for meeting the expenses of a scientific expedition, which is now carrying out further plague investigations in India.

Cases of Necrosis.

Sir Charles Dilke asked the Secretary of State for the Home Department whether, in addition to the case of necrosis reported in March, two other cases had occurred recently at the same factory.—Mr. Akers-Douglas replied: Yes, sir. Two other cases have been reported since from the same factory. One was the case of a woman employed as a boxer of thoroughly dried matches who had a tooth extracted and returned to work directly afterwards without informing the firm and obtaining a certificate of fitness as required by the special rules. The attack was a first attack. The other was the case of a man who had phosphorus poisoning some years ago and had been employed since in other work, latterly as a night watchman. In the latter employment, which is one lying outside the scope of the rules, it would be his duty to visit the dipping and other rooms at night but it is doubtful at present whether the case is one of phosphorus necrosis at all. I am now in possession of reports in all three cases, though the investigation of the third case is not yet complete and in view of the fact that they all occurred at one factory I have called for a special report on the circumstances in which they arose and on the working of the special rules in that factory.

In the Interests of Public Health.

Mr. Field asked the President of the Local Government Board whether he had authorised the issue of a circular by the medical officer of health of Tottenham district requesting meat traders to provide forks for the use of intending purchasers to hold and to examine meat; and, if so, what section of the Public Health Act or other statute empowered such action.—Mr. Gerald Balfour said: The circular was not authorised by me. I understand that it was not intended as a request which could be legally enforced but rather as a suggestion in the general interests of the public health.

BOOKS, ETC., RECEIVED.

KRUGERSDORP AS A HEALTH RESORT.

WE have received from Mr. W. Gem, the medical officer of health of Krugersdorp, the following interesting particulars:—

> Krugersdorp, so named after the late President of the Transvaal Republic, is the chief town on the West Rand. It is situated on the northern slope of the Witwatersrand, with an uninterrupted view of the Magiliesburg range of hills, and is about one hour's run from Johannesburg, a good train service affording easy intercommunication with that city. The town is divided by wide streets, macadamised throughout, and with a row of eucalyptus trees running down each side. In the centre of the town there is a large market square, also surrounded by gums. The town council is of a most progressive type. There is an efficient sanitary service and the pail system has been adopted and the excreta and refuse are removed daily and carted about two miles out of town and there disinfected and buried. The climate of Krugersdorp and the West Rand in general is second to none. The town lies in subtropical latitudes, yet its height above the sea level (6800 feet) insures for it invigorating and pure air at all seasons. The summer heat, at no time unendurable, is tempered with frequent and mild rains, the heat rarely exceeding 80° F., and the nights are cool and pleasant. In winter there is a still, cold, dry atmosphere, so that the bracing effects of the cold are felt without the irritation produced by too rapid evaporation from the respiratory surface. Snow seldom falls, while ice is only found in thin layers. The cloudless and azure skies are characteristic. The absence of violent winds which in other parts of the Transvaal and Cape Colony are a prevailing element enhances the value of the West Rand as a health resort. The water is obtained from gravel hillocks held up by underlying clay and is pure and wholesome. It has been tested and analysed on several occasions with a most favourable result. The town is shortly to be lighted by electricity, improvements are to be made all round, and further railway communications are anticipated in the near future. There are various places of interest in the locality. A sanatorium will be constructed in a short while just outside the town with a good approach road.
>
> Now that the agricultural department is placing farming on a scientific basis and importing stock there will be a supply of good fresh meat and milk which have been unobtainable up to the present. Several well-qualified medical men have settled in practice at Krugersdorp. The great feature of Krugersdorp is its low death-rate and more especially from chest complaints. Cases of phthisis in its earlier stages or consolidation of the apices of the lungs do remarkably well but when it has gone on to the cavernous stage it is highly undesirable for a medical man to send such patients out here, far away from home and friends and the luxuries of England. A few cases of cavernous phthisis have done well under various treatments, such as inhalations of creasote, guaiacol carb., cyllin, and other antiseptics, but such cases should not come out here, as the diet to be obtained is not suitable for them.

ENTERPRISE.

AN enterprising firm of tobacconists appears to be circularising the medical profession and making offers to let medical men have certain cigars at a low price if they will be so obliging as to recommend the brand to their patients. We hope that the firm will find medical men not readily seduced into recommending their wares. The cigars may be good enough, but either they are worth more money than is asked of the medical profession or they are not. If they are worth more the medical profession is being bribed; if they are worth less it is being exploited and neither position is to be coveted.

THE COUVADE.

To the Editors of THE LANCET.

SIRS,—Much curious information upon the subject of the "couvade" cognate to the inquiry of your correspondent may be found in "The Mystic Rose," by E. Cawley, M.A., London, Macmillan, 1902.

I am, Sirs, yours faithfully,
C. J. W.

AIR-BORNE INFECTION FROM SMALL POX HOSPITALS.

To the Editors of THE LANCET.

SIRS,—Your leading article in THE LANCET of June 10th prompts me to ask whether the gases escaping from the ventilating pipes connected to "waste water," "soil pipes," and drains by means of the present universal (and in my judgment entirely wrong) system of open tops do not exert even a more powerful influence in spreading small-pox, fevers, &c., than the moving in and out of patients and those attending upon them?

I am, Sirs, yours faithfully,
SANITARY ENGINEER.
June 12th, 1905.

POSTAGE STAMPS AND CHARITY.

FOR a great many years [illegible] lon of a million used postage stamps would [illegible], has had almost universal acceptance. An arrangement has now been made, however, by which for the future for every million stamps collected two sick children will be admitted to the North-Eastern Hospital for Children, Bethnal Green, London, E., and the name of the collector of each million stamps will be inscribed on a special list placed in a prominent position on the walls of the hospital. Particulars of this scheme may be obtained of the hospital secretary, Mr. T. Glenton-Kerr, or of the Editor of the *Girl's Realm*, 7, New-court, Carey-street, London, W.C.

TO DEADEN SOUND.

To the Editors of THE LANCET.

SIRS,—Messrs. Clay and Abraham, chemists and druggists, of Liverpool, have a most effectual and comfortable ear stopper, made of rubber and priced 1*s.* a pair. As a night superintendent I wore them for two years and found them most useful.—I am, Sirs, yours faithfully,

June 9th, 1905. A. G.

To the Editors of THE LANCET.

SIRS,—Your correspondent might with advantage try plugging the ears with small ivory balls. These have been successfully used for the relief of insomnia and are, I believe, used in France by artillerymen during gun practice.

I am, Sirs, yours faithfully,
F. R. WALTERS.
June 10th, 1905.

◆

Dubious is advised not to place his diploma at the service of a company. Without entering into what might be his legal position we may say that the General Medical Council would view his conduct with disfavour.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. FRIDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M [illegible] Cross (3 P.M.), St. George's (1 P.M.), [illegible] (2 P.M.), Ophthalmic (10 A.M.), Canc [illegible] London Northern Central (2.30 P.M.), West London (2.30 P.M.), Throat, Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Royal Ear (10 A.M.).

SATURDAY (24th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex [illegible] 2 P.M.), University College (9.15 A.M.), [illegible] George's (1 P.M.), St. Mary's (10 P.M.), [illegible] A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (21st).—Royal Microscopical Society (20, Hanover-square, W.).—8 p.m. Papers:—Mr. A. E. Conrady: Theories of Microscopical Vision.—Mr. E. M. Nelson: The Tubercle Bacillus.

SATURDAY (24th).—Neurological Society of the United Kingdom (National Hospital, Queen-square).—10 a.m. Clinical Cases will be shown.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (19th).—Medical Graduates' College and Polyclinic (22, Chenies street, W.C.).—4 p.m. Dr. J. H. Sequeira: Clinique. (Skin.) 5.15 p.m. Mr. L. Thomas: The Control of Hæmorrhage during Operations.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—5 p.m. Mr. Ll. Williams: Etiology of Dental Caries.

TUESDAY (20th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m. Dr. W. Ewart: Clinique. (Medical.) 5.15 p.m. Mr. W. G. Spencer: The Treatment of Diseases of the Knee-joint.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—5 p.m. Mr. D. Hood: Clinical Aspects of Pneumonia.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 p.m. Sir W. Gowers: Some Symptoms of Tabes.

North-East London Post-Graduate College (Tottenham Hospital, N.).—4.30 p.m. Lecture:—Mr. W. Edmunds: Joint Affections in Childhood.

WEDNESDAY (21st).—Medical Graduates' College and Polyclinic (22, Chenies street, W.C.).—4 p.m. Mr. P. Paton: Clinique. (Surgical.) 5 15 p.m. Dr. A. P. Luff: The Diagnosis and Treatment of some of the Forms of So called Rheumatism.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—5 p.m. Mr. Dunn: Ametropia, its Causation, Diagnosis, and Treatment.

Hospital for Consumption and Diseases of the Chest (Brompton).—3 p.m. Lecture.—Dr. Horton Smith Hartley: Pneumothorax.

THURSDAY (22nd).—Medical Graduates' College and Polyclinic (22, Chenies street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5 15 p.m. Mr. D. Armour: Pain in Acute Abdominal Disease.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—5 p.m. Mr. Edwards: Rectal Disease.

Hospital for Sick Children (Gt. Ormond-street, W.C).—4 p.m. Lecture:—Dr. Thursfield: Enuresis.

Samaritan Free Hospital for Women (Marylebone-road, N.W.).—3 p.m. Lecture.—Dr. Roberts: Cases from the Wards.

Mount Vernon Hospital for Consumption and Diseases of the Chest (7, Fitzroy square, W.).—5 p.m. Lecture:—Dr. T. D. Lister: Pre-Tuberculous Affections in Early Life. (Post-Graduate Course.)

Royal Institute of Public Health.—5 p.m. Colonel D. Bruce, R.A.M.C.: Sleeping Sickness.

North-East London Post-Graduate College (Tottenham Hospital, N.).—4.30 p.m. Lecture.—Dr. Giles: Hæmorrhage during Pregnancy.

FRIDAY (23rd).—Medical Graduates' College and Polyclinic (22, Chenies street, W.C.).—4 p.m. Dr. J. Horne: Clinique (Throat.)

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—5 p.m. Dr. Abraham: Cases of Skin Disease

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3 30 p.m. Dr. R. Russell: Friedreich's Ataxy.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

"London and Westr

should be made payat

The Lancet Offices, 423, Strand, London, W.C.

Subscribers abroad are particularly requested to notice the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 25th, 1905.

> "The primal duties shine aloft, like stars;
> The charities that soothe, and heal, and bless
> Are scattered at the feet of Man, like flowers"
> WORDSWORTH: *The Excursion*, Book ix.

ANOTHER year has passed, and for those of us who live lives filled with the constant occupations of business or of pleasure it doubtless has slipped by rapidly. Again Hospital Sunday is at hand, and the appeal for aid is reiterated on behalf of the Metropolitan Hospital Sunday Fund and of those noble institutions which are justly objects of pride not only to London but to the whole nation. The "season is at its height," the greatest metropolis in the world, full at all times, is crowded to overflowing by thousands who visit it merely to enjoy themselves, and to all alike comes the opportunity to remember in health those who are in sickness, and to set aside for the relief of the helpless something a little in excess of their usual Sabbath almsgiving. The cry of the hospitals for aid is constant, sturdy beggars as of necessity they must be if they are to carry on their good work; beggars, however, not on their own behalf, but for the sake of others. Their need is great, and they who know what their work is cannot pretend to prophesy that it is likely to become less in the near future. On the contrary, it increases, and must increase, as the population is augmented by natural growth within and by influx from without, and as the demands of an age of progress compel hospitals as well as other institutions to move with the times.

The Change in London's Face.

The development of London never ceases and is not confined to the enlargement of its borders. Let anyone who wishes to appreciate the nature of one phase of this development alone, and of one which intimately affects hospitals, take a walk through London, particularly if during the last few years he has not seen some of the streets once familiar to him. He may go, like Dr. Johnson, down Fleet-street, or he may start from Temple Bar and go by the Law Courts to where Kingsway ends in Aldwych and Aldwych in the Strand. He may follow these new thoroughfares or proceed farther west past Charing Cross, but wherever he passes he will find change either completed or proceeding. In Piccadilly he will notice a gap where the St. James's Restaurant stood, and a monster hotel near the Green Park taking the place of a club and chambers which had scarcely been used for a decade before being demolished. In Regent-street, again, he will find the dignified and harmonious buildings of the Quadrant crumbling beneath the crow-bar of the house-breaker and all will warn him that times are changing and that with them London is changing also. It is this especially that those must remember who read of hospitals being removed to other sites or rebuilt where they have stood for years past, and who perhaps think that it is some whim for new things or some desire for display that causes the demand for hundreds of thousands of pounds to effect the demolition and the rebuilding. It is nothing of the kind. The old houses of Wych-street and Holywell-street have been swept away, together with newer and more substantial buildings in more recently inhabited localities, not because of any caprice affecting their owners or their tenants, but because the new requirements which time and human progress have brought into being have rendered the structures either obsolete in themselves or unnecessary in the places where they stood. With hospital buildings as with other structures—more so, indeed, than with private residences or with business offices—this necessity for reconstruction is forced upon those responsible for their maintenance. Hospitals are institutions with restricted means or we should not be urging our appeal on their behalf; therefore it behoves them, if they occupy valuable positions in densely crowded situations, to see that they extract the maximum of advantage from their site by placing upon it buildings calculated to fulfil their objects as completely as possible. It would be extravagance to occupy with a hospital accommodating 200 patients inadequately a space which might serve the needs of 300 and serve them better. In like manner it may be extravagance to remain in such a situation at all, but if the move is to be made a demand for funds will be necessary before the change can be effected. With hospitals, moreover, there are necessary changes to be considered connected with the advances made in medical and surgical science which alone would require structural alterations in the buildings, even if in other respects they were suitable for their purpose. Wards, operating theatres, and laboratories have to be of the most practically useful type known to science or public support will be withdrawn from an institution believed to be effete. In these circumstances buildings, once the best of their day and a model for the world to copy, have to be brought again into line with those that have outstripped them, and in the increasing advance of medical, sanitary, and social science towards the highest attainable ideals the great charities of London must not be left behind.

The Tale of Ever-increasing Expense.

The money that is laid out in rebuilding our hospitals involves an outlay of capital not needed every day and is an expenditure from which, once made, interest in the shape of efficient work will be derived for many years—perhaps for generations afterwards. In connexion with Hospital Sunday this has to be taken into account, chiefly because some may confuse the large sums laid by in permanent structural improvements with those necessarily disbursed in each financial year upon the daily up-keep of the institution. For the ordinary expenses of the upkeep of these great charities there is "nothing to show" that strikes the eye; no building, ward, or operating theatre remains to perpetuate the names of countless donors. We can only boast as a return for the money spent the knowledge that lives have been saved and that suffering has been relieved, so that the breadwinner has gone back to his work, the mother to her family, and the children to their homes, healed so far as science can heal them, and by means which without the hospital would have been beyond their reach. It is in aiding this daily and hourly up-keep that the Metropolitan Hospital Sunday Fund is annually exhausted, and it is with a view to this that the help of all is solicited to replenish its coffers. Yearly the demand grows greater in this respect also. Few will be found to suggest that as London widens its boundaries the cost of living diminishes. Householders who can look back upon the rates which they paid in 1873, when the Fund began its work, and compare them with those exacted to-day will do well to remember that most hospitals pay rates just as they do themselves, and that the rates paid by the hospitals have increased in exactly the same proportion as theirs. Housekeepers who in providing for their families endeavour to secure that such simple articles of diet as milk, eggs, and vegetables shall be of the highest possible quality, pure and fresh, will admit that this purity and freshness in London have to be paid for as luxuries by the rich, and that the simple forms of food we are speaking of are among the staple necessaries of life for those who have to be kept alive in hospitals. Let anyone acquainted with the rate of wages compare those in London with those paid elsewhere to all classes of servants and workers When the "cost per bed" of hospital maintenance in London is compared with that prevailing in other towns such questions of necessary expenditure as these have to be considered, as well as the fact that in the metropolis the claims for hospital aid are such that only the more serious cases can, as a general rule, be admitted. These points have been dwelt upon in order to show that if hospital expenditure does not diminish, or if indeed it increases and is likely to increase, its proportions are due, as a rule, to causes beyond the control of hospital committees and to circumstances which all can appreciate when once their attention has been directed towards them. Without the aid of such organisations as the Metropolitan Hospital Sunday Fund, and the help of the generous public who support it, we should find an ever-growing tale of unrelieved suffering and death. Among the names of generous men associated with the progress of the Metropolitan Hospital Sunday Fund and the maintained efficiency of the London hospitals, that of Mr. George Herring will ever be conspicuous. Again this year he has renewed his offer of adding one-fourth to any amount collected in places of worship on Hospital Sunday, his liability attaining to £25,000. Fully appreciating the position to which we have called attention above, he observes in the letter to the Secretary of the Fund, which contains his promise of help: "I hope the calls on the charitable for building purposes will not decrease the collections for the *maintenance* of the hospitals, as I think that should be the primary object." This is a brief summary of the point which we have dwelt upon and emphasised above, in the words of one who yearly gives practical effect to his view with unexampled liberality. Let others follow his example in proportion to their means, remembering that important and necessary as are the rebuilding schemes of this year or of that, the annual maintenance of the hospitals must ever be the primary object to be kept in view, or new buildings and old alike will fail to fulfil their objects. The Metropolitan Hospital Sunday Fund makes its valuable contribution to the expenses of the hospitals having regard alone to their upkeep as hospitals; and undoubtedly it is because the Fund makes no donations expressly for building or similar purposes that it benefits by Mr. Herring's splendid and recurring generosity.

Can Hospitals be maintained except by Charity?

We have referred to the generosity of the public to which the Metropolitan Hospital Sunday Fund annually appeals—a generosity which has made our hospitals the great national gift of the rich to the poor, of the whole to the sick. We here use the term "rich" to include not only those donors of large sums, founders and rebuilders of hospitals, whose wealth exceeds that of the majority of their neighbours, but also many who would possibly deny its application to themselves. These, however, are rich beyond the dreams of the poor for whom the hospitals are provided, and it is to their generosity, no less than to that of our territorial magnates and merchant princes, that our hospitals look for support. For such generosity there is a possible alternative to which allusion is sometimes made. We have mentioned the growing rates of London. It is not inconceivable that the burden of the building and of the maintenance of hospitals might be added to the rates. Against such an idea as this, however, we have protested and shall continue to do so, challenging any who may advocate it to show that the efficiency of the hospitals would not suffer under municipal control or that their cost would not be hugely increased. The growing cost of public elementary education and the increase of rates for this and other purposes are not calculated to encourage the addition of fresh subjects for expenditure to those already intrusted to popular elective bodies. Under the present system hospital managers are bound to practise the most rigid economy, and to exercise the keenest supervision over every item of their accounts, because their precarious and limited incomes necessitate their doing so. They also necessarily, as well as willingly, endeavour by all means in their power to check the abuse of the hospital's generous aid by those able to pay for medical attendance. Under a system of hospitals supported out of the public purse of the locality no question of economy would cause any hesitancy, still less any serious anxiety, for the income of the householder would always be there to draw upon and "a slight increase of the hospital rate" would meet the demand caused by any extravagance. Under such a system, moreover, all would have a right to the hospital's aid, as they now have to that of the public elementary day-school, and many who consider themselves above sending their children to such a school would not find their dignity standing in their way if free medical aid were to be had for the asking. The alternative would be the rendering of assistance from a hospital a question of Poor-law relief involving similar social stigma and disqualification, with the effect that, like the workhouse, the hospital would be considerably shunned by the self respecting poor, or would only be resorted to when it was too late. Care should be taken, and is taken, to prevent hospital abuse, but promptitude in the rendering of assistance is essential where human health or human life is at stake, and any recourse to officially imposed formalities, any limits defined and guarded by red tape, must necessarily involve delay and may cause the withholding of assistance which charity would render freely and without question. In urging the working man to give voluntarily to the hospital nearest to him or to contribute to the Hospital Sunday Fund, we would ask him to regard his gift as one of charity to those who in their time of necessity must turn to the hospital for help, and not as one which will entitle him to hospital aid on some future occasion merely because he needs a little medical attention which he can afford to provide for himself.

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1904

---

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

The only claim which any can justly raise for admission to a hospital lies in the fact that they are in need of help which they cannot obtain elsewhere and by other means. Their necessity then qualifies them and is independent of any payment which they have made. The help of the hospital is, in fact, a charitable gift, and not a right which anyone can claim on other grounds than those of bodily need and poverty.

A Reminder to those who might forget.

We have alluded to the growing population of London as causing pressure upon hospital accommodation in an increasing degree from year to year. The incoming thousands, it must be added, consist principally, or very largely, of those persons who in time of trouble go to the hospital for assistance. The wealthier class of the population in London may increase, but villas outside its borders attract many whom rising rates and the increased cost of daily living drive farther afield for their place of residence. These may earn their daily bread in London, but when Sunday comes they are not within its limits, and we venture to hope that none of them will forget the claims of the great metropolis and of its hospitals. We have before urged those who remember the calls of Hospital Sunday and who themselves have the opportunity for contributing afforded to them at a place of worship not to let others forget it, but to levy upon them such a tax as may be fitting to their pecuniary position. Many of those who do not attend public worship occupy their time, which otherwise would be spent at church or chapel, in motoring, golf, cycling, or in some other pleasurable pursuit. We do not discuss their right to *do this* but we would entreat them not to forget, amid the enjoyment of bodily recreation, those who are lying in pain in the hospital ward and who need health in order that they may keep themselves, and possibly their families, from starvation. We would also point out to them that they are spending money on their own amusement and recreation, and we ask them to spend on this one day of the year as much, nay a little more, upon others than upon themselves.

Foreigners and the Hospital Sunday Fund.

There are many too, upon whom the claims of the Hospital Sunday Fund may appropriately be urged by those acquainted with them for fear lest they should forget—persons who in the natural course of events might possibly not attend at any place of worship on Hospital Sunday where it would be brought to their notice. We have among us a very large and increasing number of foreigners. Many of these are accumulating a considerable amount of wealth in London—some more, some less. A very vast number of foreigners also are landing in our ports annually who neither earn anything that may be called a decent livelihood nor apparently have much chance of doing so. The hospital opens its doors to all alike, and if different nationalities are represented by hospitals in London specially devoted to the care of their sick poor, this does not prevent many purely British hospitals in the districts of Eastern London from being obliged to take in out of pity for their necessities a large number of sick and injured aliens. We do not for a moment desire to see such aid given grudgingly or that it should be claimed as a right on behalf of foreigners through any

An Exceptional Effort needed in 1905.

While money—much money—must be looked upon as a necessity for the maintenance of hospital efficiency the fact must be recognised that there are times and seasons when it is more easy to plead the cause of charity successfully that at others An epoch of continuous commercial prosperity may render money plentiful in the pockets of those to whom such organisations as the Metropolitan Hospital Sunday Fund appeals, and the well to do are at such a time not slow to remember those others with whom, whether times are bad or good, want is ever present At other seasons the petition for aid may be urgently made on the ground of some incident of public importance, some cause impelling us to mark the occasion by acts of generosity The death of our late revered Queen, the coronation of King Edward VII, and his recovery from illness afford instances of predisposing causes which in varying degrees might well help to fill the coffers of the hospitals when we consider how great the debt of the hospitals is to our Royal family and how keen and practical their interest has ever been in all that appertains to the organisation and administration of charities, and of medical charity in particular. The late war was another such cause. It was easy then to remind the public of their sons suffering from illness and wounds in South Africa and of the efforts of surgeons trained in hospitals at home for the good work which they did with unremitting industry and courage at the front. The present year, however, has been one in which so far no thrilling event can be pointed to as a stimulus to the charitable, so that, as far as impulses to give are concerned, we can only remind our readers that there has been a winter season of exceptional poverty and distress; though poverty and distress are circumstances from which we are never free. Can we then turn to exceptional prosperity enjoyed by any class or classes of society in order to beg for a display of unprecedented liberality? We fear not. And it is for this reason that we have suggested above the need for an *exceptional effort in 1905 if the revenue of the Metropolitan* Hospital Sunday Fund is to be maintained at the satisfactory level reached in past years. It is not possible to say that times are good. On the contrary, the vast population of London, largely dependent upon the commercial prosperity of the empire, has not for some six years been in a position to spend money freely, and those of the community who gain their living by providing for the ordinary requirements of their fellow citizens cannot look upon the months just past with unmixed satisfaction. We are therefore pleading the cause of the hospitals to many who at the present time are compelled by circumstances to spend less upon themselves than usual. They may only be obliged to diminish their personal expenditure so far as luxuries are concerned, but the possibility that they may therefore be less willing to give to others is one which has to be faced. To such of these—to all who may be impelled to urge bad times as an excuse for cutting down their usual contributions to the Metropolitan Hospital Sunday Fund—we would submit two points only for consideration. The one is that a gift involving no self-sacrifice cannot be looked on as a charitable gift in anything like the same degree as one which represents some luxury foregone or some pleasure untasted. The second is that in good times as in bad the work of the hospitals has to be done or the physical suffering of the poor has to go unalleviated. Manufacturers and merchants may be richer or less wealthy, and others may feel corresponding diminution of income, but the poor we have always with us. The newspapers at one season may proclaim more loudly than at another unusual distress in the East-End or among those members of the community who ever hover on the brink of starvation, but there are always enough penury and illness in London, and always a sufficient number of accidental injuries occurring in our streets, our factories, our docks, and in the homes of our poorer classes to keep the available wards of the London hospitals filled to overflowing. And as if the needs of those domiciled in London, including a foreign population of hundreds of thousands, were not sufficient, the metropolitan hospitals have claims upon their resources made by the poor of the provinces as well. The poor from districts outside the metropolitan area constitute from 7 to 30 per cent. of the inmates of the hospitals of London. This is a reason, we may say in passing, why in country as well as in London places of worship collections should be held and liberally supported on Hospital Sunday: but it was not in order to make this suggestion that we referred to the circumstance. We introduced the topic as one fact among many relevant to our contention that the London hospitals from year to year require, and are likely to require, a greater rather than a less measure of support, and that in this year 1905, which many will be prone to regard as one of impaired personal prosperity, special efforts of self-denial will be necessary in order that the incomes of these noble institutions may not be diminished.

The Need for and Cost of Convalescent Homes.

We have written above of modernised buildings and of other costly improvements which from time to time necessitate special appeals to the public for funds. Among comparatively recent additions to the efficiency of the London hospitals are the homes outside the crowded areas in which the hospital buildings are situated, where patients can complete their recovery before returning to their ordinary lives. Hospital patients, it is hardly necessary to point out, live for the most part in circumstances almost as ill-suited for the time of convalescence as for the more critical period when constant medical or surgical care is necessary. If they are kept in the hospital they are filling space which others might occupy who are in urgent need of aid. If they are sent back to their own homes their recovery must be retarded and may be prevented altogether The convalescent home, therefore, enables the work of the hospital to be brought to a satisfactory conclusion and increases the number of cases with which *it is able to deal* in the year It is a modern improvement of a thoroughly practical nature, but it is one which costs money It is possible that some may be inclined *to* keep in view the addition to the annual expenditure of an individual institution

necessitated by the maintaining of a convalescent home or homes and may regard the capital outlay involved as money spent upon a work of *supererogation* forgetting the increased number of patients which the hospital is able to treat and the added *power to* do its work more thoroughly

We have quoted in previous Supplements letters written by patients to the nurses who have tended them in the wards of the hospital *in order* to show those who subscribe to the Metropolitan Hospital Sunday Fund how truly the great institutions which they support are appreciated by those whose *misfortunes* have brought them within their walls Two such letters lie before us written from convalescent homes, and will *serve* a double purpose They will show the feelings of the humble patients who wrote them towards those *who* tended them in the hospital itself, and they will cause those *who read* them to reflect whether some addition to their gifts to the Fund may not reasonably be made on account of these homes in the country where legs that "are still a little shaky" may grow strong and where the 'poor old stump' may *harden* before its boy owner returns to fight the battle of life as a cripple The "good lady" referred to in the *second* letter no doubt is the giver of the clothes that made the writer *think* he was "the lord of the manor" The "Daddys" are, of course, the other inmates of his ward called by *a friendly nickname*

DEAR SISTER —I am very glad to tell you that I am getting on so nicely The air here seems to agree with me, I did not think I should

FLORENCE ——

GEORGI ——

Those who believe that the poor accept callously and without gratitude what is done for them would learn many lessons in our hospitals

Conclusion.—HOW MUCH?

We have suggested above that something more than the customary Sabbath offering should find its way into the bag or the plate on Hospital Sunday, and that all should remember to contribute to the collection whether present to give *in person or not* We would dwell upon this, always remembering that such other collections as may be made upon the Sundays preceding or following must not suffer thereby. We would advocate, to use a familiar phrase, no "robbing Peter to pay Paul" It may, however, be suggested that on other Sundays the gifts of worshippers for the most part are solicited in order that ministration may be made to the spiritual needs of the world On this one day bodily wants crave our attention—the bodily wants, too, of those at our doors living in our midst, with the sight of our luxury ever before them They ask for no help in their daily struggle against poverty, only for aid when illness or injury drives them from the fight How much should we give to help these? Surely a little more than usual, so special and so merciful being the purpose We have suggested the taxation of pleasure and of luxury, and to those who spend a large portion of their incomes

The Need for and Cost of Convalescent Homes.

We have written above of modernised buildings and of other costly improvements which from time to time necessitate special appeals to the public for funds. Among comparatively recent additions to the efficiency of the London hospitals are the homes outside the crowded areas in which the hospital buildings are situated, where patients can complete their recovery before returning to their ordinary lives. Hospital patients, it is hardly necessary to point out, live for the most part in circumstances almost as ill-suited for the time of convalescence as for the more critical period when constant medical or surgical care is necessary. If they are kept in the hospital they are filling space which others might occupy who are in urgent need of aid. If they are sent back to their own homes their recovery must be of research in hygiene and pathology. In many of our chief provincial cities and towns similar developments are taking place, and, indeed, they give London an example of progress in this direction with which it is very difficult to keep up. And remembering the direct interests which this vast empire has in almost all parts of the world it is encouraging to note that institutes for research have been, or are being, established in our different colonies, in India, and in various tropical regions. And this brings me to another important and promising feature—namely, the application of scientific research for particular purposes and for the study of special subjects, among the most prominent of which may be mentioned tuberculosis, cancer, tropical diseases, nervous affections, psychology, sanitation and hygiene. Other aids and encouragements to research which I can now only enumerate without any comment are the presentation of "research scholarships" to deserving individuals by the British Medical Association, certain city corporations, and other bodies, as well as by private persons; the contribution of large donations by wealthy and sensible persons who are well disposed towards the medical profession and are beginning to realise their responsibilities to particular institutions or for particular purposes; and the fact that their Most Gracious Majesties King Edward and Queen Alexandra, as well as other members of the Royal Family, take such a warm and practical interest in research work and in its results in certain directions.

As immediately relevant to our commemoration of Harvey to-day it would be entirely within my province to discuss in historical sequence the progress that has been made with regard to the circulatory system since his time and to indicate the present state of knowledge and practice in relation to that system. To enter upon this subject, however, at any length is obviously out of the question within the time at my disposal, and I must content myself with a very general summary, leaving further discussion for the published oration. At the outset it is necessary to bear in mind what Harvey really did discover and demonstrate and thus to have some definite starting point for studying the results of further investigation and progress. Of course, many anatomical facts relating to the heart and vessels as well as that there was a movement of the blood were well known before Harvey appeared on the scene and these facts he fully appreciated and utilised, at the same time correcting anatomical errors and controverting the erroneous conclusions and theories of his predecessors. I take it for granted that this learned assembly is familiar with the details of the work and teaching of Harvey in establishing among other points the muscular structure and contractility of the heart, whether known previously or not, and in demonstrating its mode of action and mechanism and the effects thereby produced; at the same time proving that the blood moved in a constant stream and in a definite *direction, there being a complete double circulation*, pulmonary and general. He sums the matter up in the words: "By the impulse of the heart there is a perpetual movement of the blood in a circle." Though he had absolute proof that the blood did somehow find its way from the terminal arteries into the commencing veins he did not know how and conjectured that it was the result of percolation through the organs and tissues. With his simple magnifying lens or *perspicillum* he could not see the delicate network of capillaries, which were only observed when the microscope was sufficiently developed, by means of which the capillary circulation in the frog's lung and mesentery was first observed by Malpighi and the definite continuity of the circulation thus established. Nor did Harvey understand the meaning of the pulmonary circulation, knowing nothing about the mechanism or chemistry of respiration, which were only discovered at a much later period, and this constituted a most important advance. Although described in his time Harvey would not acknowledge the existence of a distinct absorbent system.

[Dr. Roberts then proceeded to summarise the methods by which knowledge and practice i[illegible] system had been advanced since [illegible] those of more modern date. He [illegible] value of post-mortem examinations in this connexion and of *the systematic study and teaching of morbid anatomy*, which no doubt Harvey thoroughly recognised, but which for a long period afterwards was entirely neglected, and also nowadays of morbid histology. He further pointed out how much had been achieved by intelligent clinical observation and investigation, and how far progress had been aided by the introduction of the stethoscope and by other instruments or special apparatus of various kinds for demonstrating or recording the movements of the blood, the arterial tension and blood pressure, and other phenomena connected with the circulation. The chief *methods of examining* the blood were briefly referred to.

As illustrating the advances made in our knowledge in relation to the nature, etiology, and pathology of morbid conditions of the circulatory system, the orator referred to gross organic lesions of the heart and vessels, the different forms of acute endocarditis, acute and chronic changes affecting the myocardium, functional disorders and their relation to the nervous system, thrombosis and embolism, the mutual pathological effects produced between the cardiovascular and other systems, the principal changes and diseases associated with the blood, and certain special morbid processes or lesions with which the circulatory system is concerned. Dealing with clinical investigation in relation to the heart and vessels, while fully recognising the value of the various instruments and apparatus already referred to, he insisted upon the importance and sufficiency of the simpler physical methods in ordinary use as a matter of general routine and incidentally referred to the essential help not uncommonly afforded by direct auscultation with which Harvey was certainly acquainted. For adequate examination of the blood of course special methods are usually essential, in addition to the mere use of the microscope, and the help of a skilled expert is not uncommonly required. Reference was made to the employment of the Roentgen rays in examining the heart and pericardium in certain cases and in the diagnosis of aneurysm.

With regard to treatment, after alluding to Harvey as a practitioner and to the remedial measures which he seemed chiefly to employ, Dr. Roberts dwelt upon the great advances which had been made in the therapeutics of the circulatory system within modern experience; how definite our knowledge now was as to what we could and could not accomplish; and how largely we are indebted to experimental pharmacology, as well as to physiological investigation and observation, and the systematic and intelligent study of clinical therapeutics. Dealing with particular *methods and agents, he glanced at the value of* drugs and of the trustworthy active principles now to be obtained, the great importance of hypodermic and intravenous injection, the remarkable effects of certain glandular structures or their products on the circulatory system as strikingly exemplified by suprarenal extract and adrenalin, the treatment of cardiac affections by physical or balneological methods or a combination of both, the essential importance of rest in a variety of circumstances, the rational use of blood-letting and local removal of blood, the beneficial effects of transfusion of blood under special circumstances, and the extreme value of the modern treatment by injection or infusion of saline solution in certain grave conditions. Dr. Roberts also dealt briefly with the therapeutics of the blood and made a passing allusion to operative treatment in relation to the circulatory system.

The orator then referred to some of the more prominent examples of the beneficial results on an extensive scale of scientific and practical research and as being closely connected with the circulatory system drew special attention to the "brilliant victories" which have been achieved against malaria in different countries and regions, many of them forming an integral part of this vast empire. While paying a tribute of respect and admiration to all those who at the risk of life and health have gone forth to dangerous climates to study and combat *with this and other tropical diseases*, he mentioned specially Dr. J. E. Dutton, the latest "martyr of science," as he had been aptly called, whose lamented death recently occurred on the Congo, where he had gone to study sleeping sickness on behalf of the Liverpool School of Tropical Medicine. Dr. Roberts expressed on behalf of the *College their* deep sense of the great services which Dr. Dutton had rendered to the medical profession and to humanity, their profound regret at the premature cutting off of such a valuable life and promising career, and their heartfelt sympathy with his bereaved family and friends. He concluded as follows:—]

The last and most agreeable duty laid upon me by Harvey's direction is to "exhort the Fellows and Members, for the honour of the profession, to continue in mutual love and affection among themselves, without which neither the dignity of the College can be maintained nor yet particular men receive that benefit by their admission into the College which they might expect, ever remembering that concordia res parvae crescunt, discordia magnae dilabuntur." Who so fitted as Harvey to give us this exhortation at the close of his noble career! Though he could be justly indignant on occasion, his whole life was an example of simple and unassuming dignity, true courtesy and politeness, unselfishness, kindness of heart, and Christian grace and charity. Whatever may have been the state of things in days gone by it is a satisfaction to think that we may now congratulate ourselves on fulfilling Harvey's exhortation in a fairly adequate degree. A spirit of good fellowship prevails amongst us and I firmly believe that we are all cordially united by the bonds of mutual respect and esteem. Moreover, our relations with our working ally, the College of Surgeons, are thoroughly amicable and sympathetic. Thus the dignity of the College is fully maintained and an increasing influence for good is being exerted upon the medical profession generally as well as in other directions. With regard to the future position and reputation of this College in relation to scientific research and the progress of medicine there can be no doubt or misgiving when we see amongst our younger Fellows and Members so many who are endowed with great abilities, who are full of energy, intellectual vigour, and enthusiasm in their work and whose achievements have already brought them into conspicuous prominence and, in some cases, into the foremost ranks of our profession. May we not confidently hope that they will also ever keep in mind Harvey's last exhortation and unflinchingly strive to maintain the high standard of character and conduct which he has placed before them. But should they at any time feel the need of an example, a stimulus, or an inspiration, let them steadily fix their attention and thoughts upon the personality, the life, and the work of our "immortal and beloved Harvey," whom it is our privilege and pride and happiness to commemorate on this anniversary.

Lectures

ON

CARBOHYDRATE METABOLISM.

A Course of Advanced Lectures in Physiology, delivered at the University of London,

By F. W. PAVY, M.D. Lond., LL D. Glasg., F.R.S.,

HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL; CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

LECTURE I.

Gentlemen,—This is a large and important subject, and one which takes us into the question of the series of operations occurring in the applications of food, as a whole, to the purposes of life. The primary classification of the organic portion of food is into nitrogenous and non-nitrogenous. Avoiding descent into particulars, the nitrogenous may be spoken of under the head of proteid. The non-nitrogenous consists of fats and carbohydrates. There are these two distinct divisions to start with, but as we proceed we shall find that these become so intimately mixed up in their passage through the body as to lead to the consideration of the one necessarily bringing in that of the others.

The destination of food is the growth and renovation of the component parts of the body and the production of energy. For these purposes the actual seat of utilisation is within the protoplasmic or biogen molecules constituting the basis of living matter. It is here where the active changes of life occur. Food elements on the one hand and oxygen on the other enter the large and highly complex molecules of which protoplasm is composed and through the play of changes ensuing the phenomena of life are evoked. As an outcome of this proposition the food material has to reach these protoplasmic molecules and to traverse the circulatory system in doing so. In what precise manner the transit is carried out will have to engage our attention. The problem is mixed up with considerations of a complicated nature. Modern research shows that what has to be dealt with is something far otherwise than a simple passage of nutrient chemical principles into the blood at the seat of absorption and their conveyance as such to the seat of utilisation in the tissues. The blood has an intermediate part to play, in connexion with which, as I shall have to point out, there is evidence to show that living protoplasmic action is concerned.

The first stage for all kinds of food to pass through is that of preparation for absorption. Solid matter requires to be brought to the liquid state and all nutrient principles to be placed in a condition to which the property of diffusibility belongs. This is effected by enzyme action, the enzymes being products of secretion of the digestive system adjusted by nature to accomplish the purposes required to be fulfilled and, as we shall see further on, being modified by the character of the demand existing so as to meet the wants arising from the particular kind of food supply. Digestion is a necessary part of my subject in [illegible] food on to the disposal of it by utilisat[illegible]uires to be said upon the point but I do not propose to dwell to any great extent upon it. The polysaccharides—starch and cellulose, the disaccharides—maltose, lactose, and saccharose, and the *monosaccharides*—dextrose, lævulose, and galactose, are the chief carbohydrates that have to be dealt with in connexion with alimentation. Evidently in some of the lower animals an enzyme is provided that is capable of attacking and dissolving cellulose. In the human subject, however, it is doubtful if cellulose is to any material extent digested. Cytase is the name given to the cellulose hydrolysing enzyme that has been discovered but information with regard to it is in an incomplete state.

Starch may be spoken of as the most important carbohydrate entering into the constitution of our food. Whilst in the state of starch, however, it is an absolutely useless material on account of the resistance it offers to being absorbed. It readily yields, however, to the hydrolysing influence of the enzymes with which it is brought into contact and thus is placed in a position to be susceptible of utilisation in the body. The saliva and pancreatic juice contain a diastatic ferment which possesses the power of carrying it through dextrinoid stages into maltose as an end product. This is the limit of change effected by diastase. The action, however, has been found to be attended with the production of a little glucose attributable, probably, to the presence of a minute amount of the glucose-forming ferment to which the name of glucase is applied. In the intestinal mucous membrane an active glucose-forming capacity exists, so that as a final issue before absorption occurs the hydrolysis of starch presumably proceeds to the end stage of enzymic transmutation, or, in other words, to the production of glucose.

Cane sugar or saccharose may be taken next to starch. This is a very soluble and diffusible principle and therefore is in a position to pass with ease from the alimentary canal into the circulatory system. Did it pass, however, it would subsequently simply filter through the body and escape with the urine in an unutilised state. All experience goes to show that saccharose as such is not susceptible of application in the system. It remains untouched by the living protoplasm and therefore cannot take part in the operations of life. Virtually *holding the position* of extraneous matter it is dealt with by the system accordingly. It is most easily, however, placed in an altered state by enzyme action and thereby rendered serviceable. Invertase is the name of the ferment that accomplishes this work and its effect is to insert a molecule of water and resolve the body into a molecule of dextrose and a molecule of lævulose. The small intèstine is known to contain this enzyme. It is stated that the stomach does not. I have found however,[1] that to a certain extent it does, and that introduced into the stomach when digestion is going on saccharose is pretty extensively converted into glucose. In the ruminant animal a modified state of things exists. The intestine possesses very little transformative energy—not more than is observed in the case of the stomach with animals generally. The inverting power is situated in the multiple stomach and is possessed by the paunch and manyplies to a much higher degree than by the reticulum and by the reed or true stomach. Thus means exist through the provision of enzyme action in connexion with the alimentary canal for placing ingested saccharose in a utilisable condition. These means must very efficiently fulfil their object, seeing that if saccharose were allowed to reach the circulation it would filter off as waste material with the urine and it is not observed to do so. I have examined the portal blood after the experimental introduction of large amounts of saccharose into the stomach and have obtained no evidence of its presence. By excessive feeding with cane sugar the urine may be rendered [illegible] sugar found. In [illegible] as glucose. Apart [illegible] not exist. This is proved by the intravenous and subcutaneous injection of cane sugar being followed by no signs of the production of glucose. Both the blood and the urine are found to give evidence of the presence of cane sugar but none of produced glucose.

---

[1] Physiology of the Carbohydrates, 1894, p. 94.

Observation on the yeast organism teaches us exactly the same as we learn from what is observable in connexion with the animal system. Cane sugar is of no use to the yeast cell. Its protoplasm will not touch it for functional application. By the invertase, however, which the organism contains transformation into glucose is effected and now the application occurs. The cane sugar molecule, it may be considered, is not of a nature to be susceptible of being anchored on by, and incorporated into, the protoplasmic molecules of the yeast and as long as it remains in an unchanged state it resists being influenced, just as it resists being touched when introduced into the circulatory system of an animal. Lactose holds a similar position to cane sugar or saccharose and whilst existing as such is not susceptible of protoplasmic utilisation. It is a disaccharide and when hydrolysed splits into a molecule of dextrose and a molecule of galactose. The enzyme that effects this change is called lactase. Knowledge regarding this enzyme has not been extensively worked out. Its chief seat appears to be the mucous membrane of the small intestine and it may be assumed that ingested lactose here undergoes transformation preparatory to absorption from the alimentary canal. As with saccharose it is noticeable that lactose reaching the alimentary canal of a diabetic passes off as glucose in the urine. Evidence is here afforded of the actual occurrence of the change within the system.

It thus appears that each of the carbohydrates that has been spoken of requires to undergo full hydrolysis into a monosaccharide to become fit for utilisation. Starch evidently does not stop at the disaccharide state of maltose, but this, like its congeners saccharose and lactose, passes on into the monosaccharide form. It is seen that by enzyme action the non-utilisable carbohydrates are put into a state to be susceptible of appropriation by living protoplasm, and adapta- [illegible] particular require- [illegible] Nature is a matter of [illegible] directions. When the food is not of the character to require the action of a diastatic ferment none is provided. The salivary glands of the infant are not developed at the first period after birth when milk constitutes the natural food. At this time also the pancreatic juice has no power of digesting starch. Bainbridge[1] has recently investigated with respect to lactase the adaptation of the pancreatic secretion to the nature of the food. Independently of the nature of the food lactase is always present in the mucous membrane of the small intestine, but in the case of the pancreas its production is dependent upon whether the animal is being fed on milk or not. In biscuit-fed dogs neither the pancreas nor its secretion contains any lactase. In milk-fed dogs, on the other hand, after the continuance of the feeding for two or three weeks lactase is to be discovered in both the pancreas and its secretion. The mechanism of this adaptiveness has been worked out and found to depend on the influence of the ingested lactose on the mucous membrane of the small intestine. Through the interaction occurring a "tangible something" becomes developed which reaches the blood stream and by it is carried to the pancreas, where it gives rise to the production of lactase for assisting in the digestion of the lactose that is entering into the composition of the food. This "tangible something" which acts upon the secreting cells of the pancreas in the manner that has been mentioned is susceptible of being extracted from the intestinal mucous membrane and produces its effect on being artificially injected into the system. For example, observation has shown that the subcutaneous injection of the extract obtained from a milk-fed dog leads to the production of lactase, whilst with the extract obtained from a biscuit-fed dog no effect occurs.

The object of digestion is the preparation of food for absorption and the several changes in carbohydrate matter that have been referred to fall within the scope of this process. Ideas regarding what is wanted for placing nutrient matter in a suitable position for application in the system have in recent times undergone great development. In this remark I have in view the molecular conformation that is needed to be provided to permit of entry into living protoplasm and thence of taking part in the metabolic changes occurring, a point upon which I shall have much to say later. Formerly it was considered sufficient to regard digestion as bringing the food into a liquid and diffusible state so as to be rendered fit for the occurrence of absorption in compliance, as the idea ran, with the physical laws of osmosis.

It is interesting to look back upon the crude state of knowledge of organic chemistry that existed when the study of the physiological relations of sugar was first started. But little was known about precise methods of preparation for analysis, and analytical procedure had none of the delicacy and precision with which they are invested at the present day. Instead of any actual quantitative determination of sugar in the blood of different parts the estimation was based simply upon the character of the copper test reaction that was obtained. Regarded as a heat producer, the sugar molecule was supposed to undergo direct oxidation in the manner that combustion is carried on in carbonaceous matter around us, and originally the lungs were looked upon as constituting the seat of combustion on account of arterial blood, owing to the mode of experimenting pursued, being regarded as containing to a pronounced extent less sugar than that of the right ventricle. My first experiments upon the physiology of sugar were directed to ascertaining if the destruction of sugar supposed to take place during the transit of blood through the lungs of the living animal would do so during transit through excised lungs subjected to inflation in imitation of respiration. For obtaining the blood for injection I resorted to catheterism of the right ventricle of another animal and this led up to my finding that right ventricular blood during life was not charged with sugar in the manner that had previously been supposed from the condition observed when collected, as had hitherto been done, after the destruction of life. Seeing that there was this disparity between right ventricular blood collected during life and that obtained after death without the adoption of precautions now known to be necessary to escape from the effects of post-mortem alteration it occurred to me that investigation ought by rights to be extended to the liver to ascertain the position in which this organ stood in relation to ante- and post-mortem conditions. I must confess I did not at starting expect to obtain a result different from what had hitherto been met with. On experimenting, however, in a manner to obtain a representation of the condition of the liver at the moment of death it was found that there was no more evidence afforded of the presence of sugar than is derivable from the examination of other constituents of the body. Thus in the case of both right ventricular blood and the liver experiment showed, when conducted in such a way as not to allow time to elapse for the influence of post-mortem change to be exerted, that the conclusions which had been previously formed and which had led to the establishment of the glycogenic doctrine were based upon a faulty foundation.

The glycogenic doctrine also included the destruction of the sugar alleged to be produced by the liver and poured into the circulation through the hepatic veins. After the lungs were no longer looked upon as the seat of destruction the systemic capillaries were assigned as constituting the position in which combustion of sugar, for it has been customary to speak of it as a process of this simple nature, occurred. In support of this view experimental evidence was advanced representing arterial blood as containing considerably more sugar than venous. This, it is known, I could not find to be the case, a large number of carefully conducted experiments having resulted in showing no real difference as regards amount of sugar between the two kinds of blood.

---

[1] Journal of Physiology, vol. xxxi., p. 93, 1904.

Modern investigators have supplied confirmatory testimony and even Lépine, one of the foremost and staunchest supporters of the glycogenic doctrine, has joined in giving expression to a similar conclusion. In the *Comptes Rendus* of the Académie des Sciences for the *séance* of Nov. 2nd, 1903, Lépine and Boulud, in the first place, referring to what they stated in a previous communication, say that very often there exists more sugar in the blood of the carotid artery than in that of the right ventricle, and then proceed to affirm that in some cases at least more sugar is found in venous than in arterial blood. An example cited gives 0·80 per 1000 for the arterial and 0·86 for the venous. What a change of front to be assumed by the French school! An experimental record supplied in former days by Bernard showed a diminution by half of the sugar in arterial blood during transit through the capillaries to the veins, the actual figures belonging to the experiment in question being 1·450 per 1000 for the arterial and 0·730 for the venous blood. With the knowledge we now possess it may be confidently asserted that experimental fallacy must have here existed. If in accordance with the abovementioned statement of Lépine the right ventricular blood may contain less sugar than the arterial and the blood in the arteries less sugar than that in the veins what, it may be asked, becomes of the glycogenic theory in connexion with which it has been all along contended that exactly the reverse order of things has to be dealt with?

Although the experimental evidence showing the fallacious ground on which the glycogenic doctrine has been built seems to be pretty generally accepted, a lingering idea appears to prevail that the sugar derived from the food passes as such through the circulation to the tissues where it serves for utilisation. Undoubtedly the carbohydrate must reach the tissues, but the great point in connexion with the matter is as to the form under which the conveyance takes place. I will proceed to deal with this question and I think it will be seen that it is quite incompatible with the circumstances existing that a small molecular body like sugar can constitute the medium for the transmission of food carbohydrate from the seat of absorption to that of utilisation.

Everything points to the impossibility of keeping the sugar molecule within the limits of the circulating current. When circulating through the kidney it cannot be prevented from escaping like other small molecular bodies and making its appearance in the urine. Impermeability of the kidney to sugar has been spoken of and suggested as a means of permitting sugar to reach the tissues without running off with the urine. I consider it may be confidently asserted that this suggestion has not a vestige of real support. No matter in what way sugar reaches the circulation it, in proportion to the extent that it does so, shows itself in the urine. The urine thus becomes an indicator of the state of the contents of the circulation as far as sugar is concerned.

Let us pause for a moment and view this matter by reference to our present-day notions of the mechanism of renal secretion. From the method of experimenting that has during the past few years been adopted our knowledge upon this point has been deprived of much of the speculative character that formerly belonged to it. The first event may be pretty safely concluded to be a simple filtration through the Malpighian tuft into Bowman's capsule. In this filtration the water of the blood plasma carries with it, proportionately to their presence, the crystalloids or small molecular bodies—urea, salts, sugar, &c.—that may exist in it, just as happens when water holding in solution various crystalloidal substances is thrown upon an ordinary filter. It is impossible to conceive that any differentiation could occur and that the sugar molecules could be held back whilst molecules of an allied nature should be allowed to pass. Pressure is at work in connexion with the filtration so that the fluid is driven through the walls of the glomerular capillaries. The next event is the passage of the filtrate along the uriniferous tubules where it becomes altered in character and transformed into urine by the agency of the tubular epithelial cells with which it is brought into contact. These are secreting and absorbing cells. They have been likened in their action on the fluid in transit through the tubule to the cells lining the intestinal canal (Cushny). The rate of transit plays an important part. When, as under high blood pressure and renal arterial dilatation, the filtrate is excessive, it may travel through the tubule with a velocity that permits but little alteration to occur, but when the transit is slow evidence of selective reabsorption is presented. Water is reabsorbed freely and, as is noticeable in the intestine, sodium chloride is more freely taken up by the cells than sodium sulphate and sodium phosphate. The cells apparently, like other cells of the body, show no disposition to touch urea. Sugar, presumably, is taken up to some extent, and, further, a modifying effect is in some way or other produced, inasmuch as that which passes on with the urine, as will be seen later, has a lower cupric oxide reducing power than the sugar of the blood. Either an influence is exerted by the cells on the sugar or it might be that the glucose is taken up by the cells in preference to the other sugars belonging to the blood.

I will now proceed to illustrate the relationship existing between blood and urine with reference to sugar by the evidence derivable from its experimental introduction into the system. A little time back I undertook a series of experiments on the intravenous and subcutaneous injection of different sugars. The results were published in the *Journal of Physiology*, vol. xxiv., 1899, the title of the paper being "An Inquiry into the Effects on the Blood and Urine of the Intravenous and Subcutaneous Injection of Various Carbohydrates standing in Relation to Animal Life." The sugars employed consisted of the disaccharides—saccharose, maltose, and lactose, and the monosaccharides—dextrose, lævulose, and galactose. Upwards of 200 observations are included in the paper. The experiments were conducted on rabbits, and for the intravenous injection the vein which occupies quite a superficial position and runs close against the outer edge of the thin part of the ear was selected. Into this vessel it is easy to pass a subcutaneous injection needle without apparent consciousness by the animal and therefore without needing the exercise of restraint beyond being held in a steady position by an assistant. The sugar solution was run in from a graduated burette, to the top of which was affixed an indiarubber bag with inflator to produce the requisite pressure. From 25 to 30 cubic centimetres per minute was the rate at which it was usually introduced. Attention had to be given to secure that the blood was collected without the opportunity having been afforded for post-mortem change to occur. The method adopted was to kill by pithing and instantly afterwards to cut into the chest with scissors and snip across the heart, from which the blood, after turning the animal over, was collected in a basin. Measured by a chronograph the time occupied by pithing and the collection of the blood was upon an average about 15 seconds. The alcoholic method of extracting the sugar from the blood was adopted so as to permit of the nature of the sugar present being ascertained by taking the cupric oxide reducing power before and after hydrolysis by means of boiling with a mineral acid. The ammoniated cupric test (Pavy) which constitutes an exceedingly delicate and at the same time trustworthy test was used for effecting the determinations. The symbol K is employed to represent the cupric oxide reducing power of the sugar present as compared with that of glucose expressed as 100.

I have already said that the urine is an indicator of the state of the blood with reference to sugar. The definite small quantity of sugar in all circumstances present as a standard constituent of the blood is represented in the urine by an equally definite and constant presence of sugar. At one time it was a disputed point as to whether sugar existed in healthy urine. There may be those who remember that a controversy with some warmth introduced into it was some years ago carried on in the pages of THE LANCET. I was one of the disputants and contended on the affirmative side, grounding my position upon the crucial evidence I had obtained of reaction with the fermentation test applied to the product collected from large quantities of urine through the medium of lead and ammonia precipitation. Since this time Emil Fischer's phenylhydrazin test has set the matter completely at rest. An osazone is always readily obtainable from the extracted sugar derived from a moderate quantity of urine and it is even possible for crystals to be procured by direct procedure from the urine in its ordinary state by persons who are skilful in the application of the process. The actual quantity of sugar present is easily revealed by means of the ammoniated cupric test. Whilst Fehling's solution gives no reaction a distinctly appreciable amount is shown to be present by the ammoniated cupric test, and where Fehling's solution gives, as is often seen in concentrated urine, what may be considered as an approach to a reaction somewhat notably high figures, certainly in view of the fact that normal urine is being dealt with, may be obtained. We speak of urine as being free from sugar when no perceptible reaction is given by Fehling's solution, but all the time a certain amount of sugar corresponding with that existing in the blood, is present It is the nitrogenous constituents of the urine that conceal the reaction by giving rise to the development of ammonia and thus preventing the occurrence of a deposit of suboxide No doubt these circumstances have had something to do with establishing the idea of renal impermeability to sugar and the idea arising out of it that sugar can be present in the blood without passing off with the urine

It will be convenient to state here that neither in the case of healthy urine nor in that of blood does the sugar actually consist entirely of glucose It is customary to speak of glucose as the kind of sugar belonging to the blood Observation shows that this does not represent the full truth Alike by the cupric oxide reducing power indicated before and after hydrolysis and the osazone crystals obtainable it is demonstrable that sugar of other nature than glucose is present A communication on this point is to be found

01 (On the
Urine, and
fully dealt
hich would

possess a cupric oxide reducing power considerably below that of glucose and with phenylhydrazin gave an osazone corresponding both in crystalline form and melting point with glucosazone, and another corresponding with the osazone derivable from what has been designated by Fischer and others isomaltose Probably in reality a mixture of sugars and higher dextrins exists presenting a condition that will serve to account for the very varying degrees of cupric oxide reducing power that may be met with

Before referring to the injection of sugar experiments it is advisable that a representation should be given of the state of blood and urine existing under normal conditions The following observations serve this purpose —

Normal Cardiac Blood

	Sugar per 1000		
Animal	Before hydrolysis	After hydrolysis	K
Rabbit	0·997	1·407	71
	0·993	1 255	79
	0 967	1 261	74
	0 939	1 458	64
	1 261	1 740	72
	1 039	1 553	67
	1 316	1 7[illegible]0	73
	1 170	1 520	77
	0 992	1 325	75
	1 116	1 700	65
	1 088	1 300	83
	1 200	1 630	75
Mean	1·089	1 495	73
Cat	0 9[illegible]6	1 136	86
	1 000	1 190	84
	0 883	0 975	90
	0 712	1 030	69
	1 026	1 409	72
	0 684	1 104	62
Mean	0 880	1 140	77
Dog	0 860	1 300	66
Horse	160	1 550	[illegible]

All the above instances apply to ordinary conditions as regards food and it is seen that in the vegetable feeder the figures stand a little higher taken as a whole than in the animal feeder but there is not any large difference noticeable and looked at individually irregularity is perceptible To ascertain the condition existing apart from any question of food animals were taken after fasting for a period sufficient to occasion not far short of a disappearance of glycogen from the liver The following were the results given —

Cardiac Blood of Fasting Animals

	Sugar per 1000		
Animal	Before hydrolysis	After hydrolysis	K
Rabbit	1 28	1 73	73
	1 49	2 13	70
	1 46	2 06	70

I have previously directed attention to the condition of the blood taken after a period of fasting. I will likewise do so for the urine. The specimens were derived from the same set of observations.

Looking at these observations it is noticeable in every instance that the cupric oxide reducing power after treatment with the mineral acid is conspicuously higher than that before. It is further noticeable that K runs in a decidedly lower range of figures in the case of the urine than in that of the blood. This I consider has a bearing upon the direction taken by sugar within the animal system and I shall have occasion to comment upon it later. As regards the genesis of the increase of cupric oxide reducing power by the agency of the acid it is only, as I have previously said, by hydrolysis of a carbohydrate or cleavage of a glucoside that the phenomenon can be accounted for.

It follows from what has preceded that not only does healthy urine contain a definite amount of sugar but that the sugar present is not to be regarded as consisting simply or even mainly of glucose. Uric acid and creatinine are cupric oxide reducing bodies and we must not be oblivious of the fact that they must contribute something towards the production of the cupric oxide reducing result obtained. They are not present, however, to a sufficient extent to answer for much in this direction and they can have nothing whatever to do with the increased figures obtained after hydrolysis by treatment with the acid. As a source, indeed, for the production of these increased figures we can only look, as I have stated, to the presence of carbohydrate matter of lower cupric oxide reducing power than glucose or to the liberation of sugar from a glucoside. The phenyl-hydrazine reaction shows that a maltose type of sugar is present, but to account for the results frequently seen to have been obtained the presence likewise of much lower cupric oxide reducing carbohydrate matter than this is needed. That glycogen or animal gum cannot be advanced as the source of explanation I have found is rendered evident by the agency of alcohol in which these principles are insoluble. Urine has been evaporated almost to complete dryness and then extracted with alcohol. The filtered alcoholic extract after evaporation and subjection to the acid treatment has given the same character of result as the urine in its ordinary state.

The amount of sugar that may be found is seen to be very variable. The degree of concentration of the urine seems to be the main factor in connexion with this point. It is a matter of common observation to find in applying the ammoniated cupric test to ordinary urine that it is specially in high specific gravity specimens that the maximum amounts are met with. Indeed, with very high specific gravity specimens it is not an unusual event for Fehling's solution to give a greater or less degree of reaction and instances have from time to time occurred in which the result has been interpreted as indicating the existence of an abnormal glycosuria. The medical practitioner, in fact, requires to be on his guard not to be misled by the result obtained on testing a high specific gravity urine. I might adduce many examples in illustration of what I have stated about the relation of the sugar indication to specific gravity. I will be content with the following. The first two specimens in the list for the human subject were obtained from the same individual and were passed at periods within a few hours of each other. One was of specific gravity 1008 with the sugar indication mentioned of 0·91 per 1000 before hydrolysis and 1·89 per 1000 after. The other had a specific gravity of 1024 with a sugar indication of 2·87 per 1000 before hydrolysis and 5·05 per 1000 after. In an instance where I took the sugar indication of urine of specific gravity 1002 it was found to stand at 0·34 per 1000.

Not only in all urines is there seen to be a decided amount of sugar present but in some which must nevertheless be regarded as falling within the normal category the amount reaches a point that would hardly have been looked for under the notions that have hitherto been entertained. In the case of one of the rabbits, for instance, the figures stood at 8·80 per 1000 before hydrolysis and 16·54 per 1000 after, which gives a K of 53. The K is normal and the condition simply represents an undue proportion of normal sugar indication such as might be produced as a result of concentration. It is the elimination of glucose which is characteristic of abnormal glycosuria and if the high sugar indication had been due to this K would have stood much higher than it did. The effect of adding glucose to healthy urine is theoretically and practically to bring the figures obtained before and after hydrolysis nearer to each other and as the quantity added advances the effect of the lower cupric oxide reducing sugars that happen to be present becomes more and more thrown into the shade until it ceases to be perceptible. Thus K serves to point out, when undue sugar indication exists, whether it is the result of a heightened normal state or an abnormal output of glucose.

I have stated that it is the abnormal output of glucose that belongs to glycosuria as a morbid condition. As the result of treatment of the case the urine may be brought to a natural state and give no reaction with Fehling's solution. It will be understood, however, that it contains sugar in small amount as happens with healthy urine. In these cases a little dietetic deviation readily affects the urine and may cause it to give more or less change indicative of sugar on being boiled with Fehling's solution. The sugar may not be greater in amount than may be sometimes met with in concentrated urine from the healthy person, but on taking the cupric oxide reducing power before and after hydrolysis the resulting K is found to stand higher. The following are a few instances illustrative of this point.

Urine from Mild Glycosurics with associated Output of a Slight Amount of Sugar.

Sugar per 1000. Before hydrolysis.	Sugar per 1000. After hydrolysis.	K.

Having dealt with the normal state of blood and urine in relation to sugar I will next proceed to consider the condition observed after the direct introduction of sugar into the system by intravenous injection. When a large quantity is introduced in this way it literally runs out through the kidney as it is injected into the vein. It is almost incomprehensible the rapidity with which the sugar in these circumstances reaches the urine. It passes through the kidney almost like passing through an ordinary filter. With the injection of four grammes per kilogramme body-weight sugar was discoverable in quantity in the urine instantly after the completion of the injection. Ordinarily the injection occupied somewhere about 60 seconds and the subsequent instantaneous pithing and collection of the right ventricular blood another 15 seconds. It would be within these limited periods of time that the escape of sugar could be taking place from the kidney and yet it was found after the employment of saccharose that the urine collected from the bladder contained in one instance as much as 64, and in another 74, per 1000 of this sugar. Looking at the lengthy route to be traversed in passing through the kidney the question suggests itself whether it might not pass directly into the urine contained in the bladder by osmosis from the vessels of the organ but presumably the result is not to be accounted for in this way With dextrose dealt with in a similar manner the escape was a little less active, the highest figures given being 39 and 47 per 1000

A strikingly noticeable effect of the injection of sugar in the quantity named when the animals were not killed immediately was a greatly increased flow of urine The intensity of the diuresis was such that in the collection of the urine as a part of the experiment it was found, in order to avoid loss from spontaneous escape, that considerable vigilance was required to be exercised to keep pace with the activity of secretion The method of collection was by pressure over the bladder with the thumb

The determinations made of the amount of sugar present in the blood in the different experiments showed a variation for the different sugars, but comparative uniformity was observable for each kind of sugar On the sugar reaching the circulation two influences can be mentioned that would immediately come into operation and produce their modifying effect Water is drawn by osmosis from the tissues and the blood becomes thereby more or less extensively diluted This, it may be stated, has been found experimentally to occur There must also be diffusion of sugar from the blood into the tissues Our knowledge does not permit us to speak of any other tangible physical influence that would come into play

The following are the respective amounts of the different sugars found in the blood after the injection of four grammes per kilogramme body weight The sugar in each case is reckoned as glucose and expressed in parts per 1000

Blood collected Instantly

Blood collected from Animal killed 15 Minutes after the Injection

Saccharose	Lactose	Maltose	Galactose	Lævulose	Dextrose
12 10	8 50	8 66	8 33	7 22	7 35
12 06	10 00	7 43	—	7 50	8 17
11 66	—	—	—	7 37	8 59
—	—	—	—	—	8 59

Reviewing these figures the disparity that existed in the instantaneously collected bloods has in great measure disappeared in those collected after the lapse of 15 minutes In the former instance the disaccharides stand away from the monosaccharides in the larger amount of sugar found and conspicuously is this the case for saccharose At the end of 15 minutes, however, with the exception of saccharose, which still stands to some extent with higher figures than the rest, the sugar has fallen to a pretty approximate point

I will now give attention to the experiments in which one gramme of sugar per kilogramme body weight was injected and it will be instructive to view the results for both blood and urine set out in tabular form —

Intravenous Injection of One Gramme per Kilogramme

Thus it is seen, reading from the mean of the results, that 81 per cent of the saccharose injected ran off with the urine in the space of an hour, 48 7 per cent of the lactose, and so on for the other sugars The results tally with the information given by the assemblage of experiments already dealt with The saccharose molecule does not seem if allowed to reach the circulation as such, to be susceptible of being touched by the system and simply passes off into the urine in an unchanged state Lactose and maltose to some extent correspond but it looks as though they were partially put into a position to proceed to utilisation With considerably more force does this remark apply to the monosaccharides, the elimination of these having been upon a much more limited scale Of the three the least extent of elimination occurred with dextrose and the highest with galactose Lævulose stood not far from midway between the two It is unassimilated or untouched molecules that escape with the urine Those which pass into the assimilated state are placed in a position to be removed from liability to pass off with the urine

Intravenous Injection of 0 250 Gramme per Kilogramme

A further set of experiments was performed with the employment of a quarter of a gramme per kilogramme, means which $\frac{1}{4000}$th of the body weight In this series only saccharose and dextrose were made use of.

Saccharose

Intravenous Injection of 0 250 gramme of Saccharose per kilogramme

Dextrose

Where large amounts of dextrose are injected the sugar met with in both blood and urine shows itself in the form of glucose The quantity of unchanged dextrose is such as to swamp the sugar of a lower cupric oxide reducing nature that may be present I therefore have not considered it
necessary previou
namely, those rep
state In the case, --
are employed it is susceptible of being seen that some of it is changed by the system into a lower cupric oxide reducing body On this account I consider it will be instructive to

closing. The catheter is left *in situ* for four or five days and is then removed, being passed only when the patient is fed. As there is sometimes a little redness round the stitches at the apex of the cone it is well to remove one or two of them about this time. The redness has been especially noticed when the patient is very emaciated. The other stitches are taken out about the tenth day.

It is interesting to notice how rarely the patient retches or vomits after the operation and that very little pain is experienced. From the first he is fed every four hours, each feed consisting of four or five ounces of peptonised milk and brandy. The quantity is gradually increased till eight or ten ounces are given at a time, the amount of brandy and peptonisation being gradually diminished, egg and milk, Benger's food, &c., being substituted. As a rule, the patient cannot take more than eight or ten ounces with comfort at a time. He is generally able to get up in about ten days, but it is advisable not to allow him to get up too soon as this may cause some escape of the gastric contents and redness of the skin.

The important points in the method are: (1) that the whole cone of stomach is surrounded by muscle, and (2) the length of the cone. The muscle acts as a sphincter and effectually prevents the gastric contents escaping, and therefore excoriation of the skin is absent. In some of the patients the rectus was very much atrophied and when split each layer was very thin. But even so the escape of the contents of the stomach was prevented. In the last patient there was at first a slight leakage but the skin was only affected to a small extent and this was due in part to the fact that some sloughing occurred from the stitches being tied too tightly and the patient being very emaciated. When healing occurred, which it did in a month, there was no escape. It is obvious that if the stomach is so contracted that the cone cannot be made long enough, some other method such as Witzel's, would have to be adopted. However, in none of my cases was this difficulty met with.

One of the most striking after-effects of the operation is the recovery of the power of being able to swallow with ease. The patients in Cases 3, 11, 12, 13, and 14 were quite unable to take either liquids or solids, or only the former with extreme difficulty. Each of these patients became able to swallow such foods as custard, beef-tea, bread-and-milk, and sometimes mincemeat or mashed potatoes. This

TABLE OF CASES OF GASTROSTOMY FOR CARCINOMA OF THE ŒSOPHAGUS.

Case.	Sex.	Years of age.	Duration of symptoms.	Site of stricture.	Date of operation.	Date of death.
1	M.	62	Six months. No solid food for three months. Occasionally regurgitation of food.	11 inches from the teeth.	August 20th, 1901. No. 8 catheter put into the stomach.	August 31st, 1901.
2	M.	50	13 weeks. Rapid loss of flesh and increasing difficulty in swallowing.	8½ inches from the teeth.	Sept. 2nd, 1901. No. 10 catheter used.	?
3	M.	42	Six months. Regurgitation of fluids for one month.	10¾ inches from the teeth.	June 3rd, 1902.	Jan. 3rd, 1903.
4	M.	62	Six months. For nine weeks only fluids taken.	10½ inches from the teeth.	July 27th, 1902.	Dec. 25th, 1902.
5	M.	57	Four months. Steadily increasing difficulty in swallowing solids. Unable to swallow liquids.	10½ inches from the teeth.	August 20th, 1902.	August 22nd, 1902.
6	M.	66	Three months. For one month able to take liquids only. Partial regurgitation of food on attempting to swallow.	In lower part of the œsophagus.	July 8th, 1902.	End of December, 1902.
	M.	68	Three months. Difficulty in swallowing solids. For two months there was shortness of breath. For three weeks the patient was unable to take solids or liquids.	Upper part of the œsophagus; the larynx was involved.	August 30th, 1902.	Sept. 16th, 1902.
8	M.	33	12 months. 11 weeks ago there had been severe dyspnœa. Tracheotomy was performed. Since that time the patient had only been able to take liquids.	Upper part of the œsophagus; the larynx was involved.	Dec. 23rd, 1902. No. 10 catheter.	Feb. 11th, 1903.
9	M.	60	Two months. The patient could only take liquids.	7½ inches from the teeth.	March 31st, 1903. No. 10 catheter.	April 17th, 1903.
10	M	73	Six months. Much coughing on attempting to swallow liquids.	—	May 22nd, 1903. No. 10 catheter.	June 3rd, 1903.
11	M.	53	Three months. For ten days the patient was able to take fluids only with difficulty.	14 inches from the teeth.	August 8th, 1904. No. 10 catheter.	Dec. 20th, 1904.
12	M.	46	Nine months. For a week the patient was unable to take even liquids; regurgitation.	9¼ inches from the teeth.	August 16th, 1904. No. 10 catheter.	Sept. 28th, 1904.
13	F.	40	Eight months. For four months the patient was not able to take solids; for one week he was unable to take liquids.	Upper part of the œsophagus; the larynx was involved.	Sept. 26th, 1904. No. 10 catheter.	January, 1905.
14	M.	62	Six months. For two months there had been increasing difficulty in swallowing liquids.	11½ inches from the teeth.	Dec. 23rd, 1904. No. 10 catheter.	Still living and well.
15	M.	49	Four and a half months. Severe attacks of coughing on attempting to swallow liquids.	Upper part of the œsophagus; the larynx was involved.	April 14th, 1904. No. 8 catheter.	Still living.

Remarks.—Case 1.—The patient was very ill and emaciated; no leakage from the stomach opening. Necropsy: No perforation into the trachea; the stricture was four inches below the cricoid; there was pneumonia in the right lung. Case 2.—There were secondary nodules in the liver; the lumbar glands were affected. The patient was discharged from hospital on Sept. 27th, 1901. Case 3.—June 7th: Catheter removed and passed when required. 10th: Able to take liquids. 14th: Able to take bread and milk. There was never any redness of skin around gastrostomy wound or regurgitation through the opening. Case 4.—August 1st: Catheter removed and passed when required. The patient was discharged from hospital on August 10th. There was no leakage of gastric contents. Case 5.—Necropsy: The growth was opposite the bifurcation of the trachea; perforation into the right bronchus. Case 6.—A feeble old man: a bad attack of bronchitis after operation. There was some excoriation round the stomach opening. Quite healed in a month's time; no leakage. The patient did not recover power of swallowing. Case 7.—Necropsy: The growth involved upper one and a half inches of the œsophagus and the posterior half of the larynx; there was recent septic peritonitis; there was no food in the peritoneal cavity. Case 8.—Dec. 30th: Tube removed; no leakage from gastrostomy wound. Necropsy: The growth was on the upper end of the œsophagus, involving the larynx; there was a perforation of the œsophagus in the neck, leading into an abscess on the right side of the neck. Case 9.—April 6th: Tube removed; no leakage of gastric contents. Necropsy: there was a perforation into the trachea; pneumonia in the right lung. The upper limit of the growth was below the level of the cricoid. Case 10.—May 27th: Tube removed; no leakage. Necropsy: The growth was at the level of the bifurcation of the trachea. There was a perforation into the left bronchus and into the lung; septic broncho-pneumonia and abscess in the left lung. Case 11.—August 13th: Tube removed. August 19th: Discharged; can take liquids. Subsequently able to swallow food in comparative comfort; very little redness of skin; slight leakage if too large feeds are given. Case 12.—August 27th The patient was able to take soft solids. Sept. 4th: Discharged; no redness or leakage even on coughing. 28th: Death from double pneumonia. Case 13.—Operation performed under local anæsthesia. Oct. 17th: The patient was able to swallow liquids; gastrostomy opening gave her no trouble. Case 14.—Dec. 28th: Tube removed and passed when required. The patient was discharged on Jan. 6th, 1905. There is no leakage and the patient is able to take soft solids comfortably. He feeds himself once or twice daily by the gastrostomy opening. Case 15.—April 20th: Catheter removed. May 3rd: The patient was able to swallow with comfort. Discharged on May 25th. The operation was performed under eucaine. There was some sloughing of the skin around the gastrostomy opening. Quite healed in a month; slight leakage. The patient, who was feeble and emaciated, improved much after the operation.

recovery generally occurred a week or ten days after the operation and the improvement took place to such a marked extent in one patient that he only used the gastrostomy tube twice a day In the majority of cases this improvement is only temporary, perhaps lasting some weeks, and the benefit to the patient a corresponding time Still, if one can say to the patient that he will in all probability be able to take at least such foods as these in a natural way a great point is made in favour of the operation, for the patient usually asks What will be the effect of the operation on his swallowing ? At the same time one is able to assure the patient that he will not die from starvation The probable explanation of *this recovery is that the growth not being irritated ceases* to be inflamed and consequently shrinks, the lumen of the œsophagus being thereby opened up

Another striking feature is the improvement in the general health and condition of the patient which occurs in many cases A patient who has been starving gains flesh and colour and strength Some patients have attacks of coughing whenever they attempt to swallow This is due to (1) some of the food getting into the larynx when the growth is high up in the œsophagus and possibly involving the larynx, or (2) a small perforation from the œsophagus into the air passages, or the separation between them being very thin This latter class of patient is very unfavourable for operation—e g, Cases 5, 9, and 10 may be cited Each patient died soon after the operation from perforation The first group is not so unfavourable One of my patients was a

g could be felt

in the region of the larynx Any attempt at swallowing caused a good deal of coughing On Sept 26th 1904, gastrostomy was *performed under eucaine* local anæsthesia Three weeks later the patient was able to take liquids without coughing and she lived in comparative comfort for four months having been able to do some light work and to go out The gastrostomy acted perfectly and never gave her any trouble A similar case was that of a man, aged 49 years He had a growth in the upper part of the œsophagus extending on to the arytenoids, the left cord being paralysed Gastrostomy was performed on April 15th 1905 The patient at once began to improve in general health and a fortnight later he was able to take liquids and soft solids such as minced meat without causing coughing Local anæsthesia was employed in these two cases on account of the involvement of the larynx which made the administration of a general anæsthetic inadvisable In the second case the skin around the opening into the stomach sloughed for a short *distance and this is attributed partly* to the effects of the eucaine and partly to the stitches being tied too tightly for around two of them the skin became white and necrotic In spite of this there was no escape of the stomach contents, except when the patient coughed after he had been fed, and the redness of the skin which never extended more than an inch from the stomach opening was due more to inflammatory reaction than to irritation of the stomach contents In another patient, aged 66 years (Case 6) who was also very feeble and emaciated a limited area of sloughing of the skin occurred and although this patient had a bad attack of bronchitis after the operation there was practically no leakage or regurgitation from the stomach opening

It has been objected that the track of the cone of the stomach becomes straight instead of remaining as it is made at the operation, so that the base of the cone and the apex lie behind one another, the valvular arrangement becoming inefficient It is true that in some cases the track does becomes straighter, but even when this occurs leakage does not follow because the sphincteric action of the rectus still persists Consequently any redness or excoriation of the skin is confined within the smallest limits, scarcely sufficient to cause any inconvenience, and in many cases is absent altogether (Cases 3 and 14) It is advisable to remove the tube on the fourth or fifth day and to pass it only when the patient is fed, the aperture

piece of sterilised dressing

the tube and to feed himself

than leaving the tube constantly in the stomach opening (where, in fact, it rarely stays) and putting a clip on to it None of my patients have had any trouble in passing the tube and there has been no tendency for the opening to close, as the feeds being given four hourly there is not any likelihood of the opening becoming unduly contracted

Of the 15 patients on whom I have operated nine have lived sufficiently long for an estimation to be made of the results of the operation The time the patients lived after the operation varied from six weeks to seven months Two of them are still alive—one more than five months and the other six weeks after the operation All of them were kept under observation and were seen from time to time or were communicated with by letter Not one of them regretted having had the operation performed, as the relief of the symptoms and the improvement in general health were obvious and the inconveniences of the operation were slight In Case 3 the patient enjoyed good health and was able to get *about till within a week or two of his death* In Case 14 the patient is doing work as a clerk The patient in Case 8 was confined to bed during the whole time he lived but the local condition, involving as it did the larynx to such an extent as to necessitate tracheotomy, was a sufficient explanation of this There can be no doubt that but for the gastrostomy this patient would have died two months sooner than he actually did and though his was so unfavourable a case the gastrostomy acted exceedingly well and there was no leakage from it

The short time the patients survived at once raises the question Does the operation prolong life for any appreciable length of time? The answer must always be doubtful because one can never tell how soon the growth will perforate in to the trachea or bronchus, thus setting up septic processes in the lungs This was well illustrated in Case 12 The patient was a man, aged 46 years, a small bougie could be passed into the stomach, a larger one stopped nine and a half inches from the teeth The operation was performed on August 16th, 1904, and the patient left the hospital much improved on Sept 4th For more than three weeks he continued to do well, he then died at his home from double pneumonia after two or three days' illness Cases 9 and 10 are similar On the whole, it may be said that at best the operation can only prolong the patient's life for a short time, but it saves him from dying from starvation and his death is attended by a minimum of discomfort as it is usually due to septic complications in the lungs

Five of the patients died soon after the operation One of them (Case 7) had recent septic peritonitis The region of the wound was healthy and it did not appear that the peritonitis was caused by any escape of gastric contents or was due to *food passing into the peritoneum from the* opening into the stomach The other four died as a result of perforation into the trachea or a bronchus As death took place on the eleventh, second, seventeenth and eleventh days respectively, the operation can scarcely be said to have been the direct cause of death The remaining patient left the hospital in the fourth week and was not seen again This patient had secondary deposits in the liver and lumbar glands He suffered a good deal from pain in the back which was not relieved by the operation, but the gastrostomy was acting quite well

Lastly, the important question arises, *How soon should* the operation be done after the diagnosis of malignant disease of the œsophagus has been made? It is to be remembered that the majority of patients come for treatment and advice when the symptoms are well marked, and there*fore the sooner* the operation is performed the better If, however, the patient is able to take sufficient nourishment without coughing it may be delayed provided that the patient is seen at regular and short intervals, not longer than a fortnight so that the progress of the disease can be watched If there is any increase in the difficulty of swallowing, if coughing is produced by the attempt to *swallow*, or if there is regurgitation of food into the mouth, then the operation should be advised forthwith the surgeon clearly explaining to the patient the results which may be expected It is a good plan to give the patient a liquid to drink and to see *how it is swallowed* A much better estimation of the amount of narrowing of the œsophagus can be formed by this actual observation and therefore a better guide as to the advisability of immediate operation than by what the patient says Bougies should also be passed and the size of the largest one which can be passed through the stricture, as well as the difficulty in passing it, are *important aids in* helping one to come to a decision for or against operation Unfortunately many of the patients are so emaciated and so exhausted that it is scarcely worth while advising them to undergo the operation, and, of course, when there are signs of affection of the lungs it is useless to operate

EXPERIMENTS ON THE DISINFECTION OF VIBRIO CHOLERÆ ASIATICÆ AND BACILLUS DYSENTERIÆ (FLEXNER) WITH CYLLIN AND CARBOLIC ACID.

BY D. SOMMERVILLE, B.A., M.D., D.P.H., M.R.C.P.,
LECTURER IN PUBLIC HEALTH, KING'S COLLEGE, LONDON.

(From the Public Health Laboratories, King's College, London.)

IN previous papers[1] I have discussed briefly the relative merits of certain disinfectants when applied directly to infective organisms, after the method of Rideal and Walker. The present experiments are a continuation of this work on the same lines. Care has been taken throughout that uniformity in the following conditions should obtain: time of contact of disinfectant with microbe; age of culture of the microbe used; constitution and reaction of the medium upon which the microbe is grown; vital resistance of the species of microbe used; quantity of disinfectant added to the culture; temperature of medication; and temperature and time of incubation.

A virulent culture of vibrio choleræ Asiaticæ was procured and sown in bouillon rendered slightly acid to phenolphthalein but neutral to litmus (acidity equivalent to 15 cubic centimetres normal NaOH per litre). A sample of phenol was standardised by bromine and a series of dilutions in distilled and sterile water was made. Into five sterile test tubes were placed respectively five cubic centimetres of dilutions 1 in 70, 1 in 80, 1 in 90, 1 in 100, and 1 in 110, and into each of these serially at intervals of exactly 30 seconds five drops of a 24-hours bouillon culture of vibrio choleræ incubated at 37° C. were deposited. Continuing the 30 seconds interval a single loopful was removed in turn from each of the medicated cultures after careful shaking and sown in a bouillon tube. The platinum loop was thoroughly sterilised after each inoculation. All vessels, flasks, tubes, pipettes, &c., used in making dilutions were also previously rigorously sterilised. The medicated culture tubes and bouillon tubes during manipulation were held in such oblique position that all extraneous organisms floating in the atmosphere were excluded. 30 bouillon tubes were thus inoculated, each at an interval of 30 seconds later than the previous. The room temperature averaged 16° C. The inoculated tubes were then removed to a 37° C. incubator for 48 hours, at the end of which time in this case nothing had grown. A second series of dilutions of phenol were tried with like result, the inoculated tubes being allowed to remain in the incubator for 72 hours.

Table I. shows that pure phenol in dilution of 1 in 160 killed all the cholera organisms, but that a dilution of 1 in 165 applied for two and a half minutes allowed growth in 72 hours. It may here be noted that whereas bacillus typhosus and the Klebs-Löffler bacillus, experimented on previously in the same way, always grew within 48 hours if they grew at all, the vibrio choleræ remained in the bouillon apparently dead for 48 hours, after which time growth commenced and was distinctly visible within 72 hours. Further, it may be recorded that working with the above-mentioned slightly acid broth and the dilutions indicated in Table I. no growth appeared in 72 hours, nor did growth appear until a dilution of 1 in 200 was reached. Acid broth was accordingly discarded and an alkaline form (10 cubic centimetres normal NaOH per litre) used instead through which the results of Table I. were obtained. This indicates, I think, that the acidity of the broth inhibited the growth of the cholera organism. In order to eliminate such inhibition alkaline bouillon was used for all further work on vibrio choleræ.

Carbolic acid coefficient, $\frac{5500}{170} = 32\cdot3$

represents the completion of the work by which the values of these bodies as disinfectants have been accurately ascertained. It is here seen that cyllin in dilution of 1 in 5500 is unable to destroy the life of the organism in seven and a half minutes but able to effect its destruction in ten minutes and that pure phenol in dilution of 1 in 170 performs exactly the same work in the same time.

It was found that the slight acidity in the bouillon which seems to inhibit the growth of the cholera organism has no such effect on bacillus dysenteriæ (Flexner). Accordingly in working with this organism the acid bouillon was used throughout.

Table IV. shows a trial series intended to fix the death point (in terms of time and quantity of phenol) of Flexner's organism. Table V. represents a further trial series in

which cyllin is put in competition with phenol. Table VI. fixes accurately the relative powers of these two disinfectants under the conditions described.

ON THE TREATMENT OF RINGWORM OF THE SCALP BY MEANS OF THE X RAYS.

BY H. G. ADAMSON, M.D. LOND., M.R.C.P. LOND.,
PHYSICIAN TO THE SKIN DEPARTMENT, PADDINGTON GREEN CHILDREN'S HOSPITAL.

IT is now generally recognised that ringworm of the scalp cannot be cured by the application of parasiticides, since no method has yet been discovered by means of which such remedies may be made to penetrate sufficiently deeply into the follicle to destroy the fungus. Hitherto the alternative has been to use methods which will cause sufficient folliculitis to loosen the hairs, so that they fall out, or that they may be easily extracted, bringing the fungus with them. By the employment of strong irritants, such as croton oil, an acute inflammation may be produced with rapid fall of the hair, the cure being complete on the subsidence of the inflammation. But such applications require extreme care and can only be applied to small areas or to isolated hairs by needling, otherwise there is danger of actual destruction of tissue and of the hair papillæ with permanent scarring and loss of hair. For large or multiple patches the usual treatment has been to rub on strong irritants, such as chrysarobin, crude izal, compound citron ointment, oleate of mercury, &c., daily over a long period, so that only a mild folliculitis is produced. This treatment, which is tedious and often painful, must often extend over many months or even years.

In rare instances it has been noticed that while under treatment and without any obvious production of folliculitis the ringworm hairs after a time drop out, leaving smooth bald patches, on which eventually fine downy hairs begin to grow. Here there has apparently been some disturbance of nutrition of the hair. Dr. H. Aldersmith states that he has seen this curious result a few times from treatment chiefly with "boric acid," ether, and spirit lotion, and also with "gas-water," and he remarks that "if this '*artificial alopecia areata*' accidentally comes on during treatment it is a most fortunate thing, as the whole of the places generally follow suit when one undergoes this change and the case gets well.' In fact," he says, 'my chief experiments during the last few years have been an effort to discover something that will always cause the diseased hairs to fall out from patches of ringworm, for I fully believe this troublesome disease will in time be cured by this method and not by discovery of new parasiticides."[1]

This prophecy had been fulfilled by the application of the x rays in the treatment of ringworm. By this means the hair of the part exposed to the rays may be made to fall, leaving a smooth bald area entirely free from stumps, and when this grows again, after an interval of some weeks, the new hairs are found to be free from ringworm. The fungus has not been killed but has come away with the old hairs and by the time the new hair grows no trace of it is left. Naturally this treatment has been tried almost since the earliest application of the rays as a therapeutic measure but those using it have always been chary in its application for fear of producing burns or permanent baldness. The first trials were made by Freund and by Schiff who used very short exposures so that from 40 to 50 applications were required. Others have been accustomed to treat cases in from 10 to 12 exposures, but even this method has been found too tedious and too uncertain in its results for general use. In recent years means have been devised for measuring the quality and the quantity of the rays. M. Sabouraud, whose brilliant researches have added so much to our knowledge of ringworm and its origin, has availed himself of these methods and has eventually arrived at a very simple and practicable means of applying this remedy, so that the dose necessary to produce depilation without either fear of radio-dermatitis or of permanent baldness may be given at one sitting.

By means of an ingenious device invented by Holzknecht (Holzknecht's pastilles) it is possible to measure approximately the quantity of x rays reaching any spot from an x ray tube at a given distance in a given time. In 1902 Kienbock showed that the amount of x rays necessary to produce fall of the hair from the scalp was from five to seven units H of Holzknecht's scale. It was thus easy to measure the quantity of rays and by the use of the radiochromometer of Benoist one could measure the quality. But the pastilles of Holzknecht were expensive and difficult to obtain and they were of a secret composition. M. Sabouraud in the endeavour to find a substitute hit upon the device of using pastilles made from the paper of the ordinary fluorescent screen. His radiometer[2] is based upon the fact (as pointed out by Villars) that the platino-cyanide of barium of the spectroscopic screen becomes darkened under the action of the x rays and changes colour in proportion with the quantity of the rays received. Given this fact, a standard tint was made corresponding to that which the platino-cyanide of barium takes when the exposure corresponds to five units H of Holzknecht's scale. All that is necessary is to expose the part that is to be depilated at a fixed distance from the tube and to place the pastille midway between the surface and the anticathode of the tube until it acquires the standard tint. The time occupied will vary with the degree of exhaustion of the tube and with the strength of the current, but so long as the pastille has reached, but has not passed, the standard tint the dose received will be that which will cause complete depilation without evil result. The hair begins to fall about 14 days after the application and continues to do so for a few days longer. It begins to grow again in from six to eight weeks and is fully grown at the end of three months.

From my own experience in the use of Sabouraud's pastilles I am fully convinced that they do afford a simple and safe means of accurate dosage. I had previously tr[illegible] [illegible] of small repeated doses [illegible] of greater length in which a[illegible] by means of a milliampère-meter in the secondary circuit and by the use of a regulating tube maintained at a uniform state of exhaustion, but I have found the simple method invented by Sabouraud to be far less troublesome and much more trustworthy. In my earlier experiments a series of cases was treated by means of repeated short exposures of 10 minutes,[3] 10 to 14 exposures spread over a period of from three to five weeks, and continued until the hair began to fall. In all cases the result was satisfactory and there was no dermatitis or permanent baldness; the hair in each instance has grown again quite normally over the areas made bald by the rays. It is obvious, however, since we now know that the hair only begins to fall two weeks after the sufficient amount has been received, that the several applications during the two weeks previous to the fall of hair were unnecessary and might have been seriously harmful. The method, too, was tedious and suitable only for single patches or limited areas. At this time there were no means of measuring with accuracy the dosage of the rays; the pastilles of Holzknecht were unobtainable in this country and, moreover, there was a tendency here to deprecate such methods of measurements. Better results were hoped for from the use of a specially constructed milliampèremeter by means of which the actual current being forced through the tubes could be measured. I undertook then another series of cases using a regulating tube and a milliampèremeter. By keeping the tube as nearly as possible at a fixed equivalent spark-length and the current, as registered by the milliampèremeter, at a fixed strength, I hoped to obtain rays of a constant quality and quantity, and it only remained then to fix the time of exposure. By making trials with gradually increasing doses I arrived at the following result—viz., that the least amount of rays necessary to produce depilation might be represented by the following factors:—primary current, five ampères; alternate spark-length of tube, three inches; current passing through tube, four milliampères; distance of anticathode from surface exposed, six inches; and time of exposure, 20 minutes. In this way I was able to produce depilation by one sitting of 20 minutes. But the results were not always quite satisfactory since it was found in practice impossible to keep all these factors constant. Sometimes depilation was incomplete and in one instance a slight radio-dermatitis was produced.

---

[1] Ringworm and Alopecia Areata, fourth edition, 1897, p. 236.

[2] Radiometre X de Sabouraud et Noiré.

With the use of Sabouraud's pastilles all these difficulties vanished, for experience soon showed that they indicate with remarkable accuracy the quantity and apparently also the quality of the rays emanating from the tube. By preliminary trial of the pastilles I was interested to find that with the ampèrage, spark-length of tube, and milliampèrage given above the time of exposure necessary to obtain the standard tint was exactly 20 minutes, thus corresponding with my own previous estimate. But when the tube was advanced to four or five inches alternate spark length the time occupied was 10 or 12 minutes only. This was in accord with Sabouraud's statement that the higher the tube the more active the rays and consequently the shorter the exposure required; it was, however, opposed to the general view that soft tubes are more therapeutically active than hard tubes. One was naturally led to suppose that the change in the colour of the pastilles was not therefore necessarily a measure of the activity of the rays as regards the effect on the hair papillæ or of their capacity to produce dermatitis. But from my experience in the exposure of scalps by this method I am fully convinced that the change in tint of the pastille does afford an accurate measurement of the amount and quality of the rays. Indeed, I believe it to be at present the only safe means which we have of dosage for therapeutic purposes.[4]

So far I have said little about the actual technique of the treatment. I shall first of all briefly summarise Sabouraud's method and afterwards mention some slight modifications which I have adopted in my own practice. Sabouraud's most recent formula stands as follows: "In order to cure a patch of ringworm by the x rays the patch must be placed at a distance of 15 centimetres from the centre of the tube, while at the same time a pastille of platino cyanide of barium paper is placed at a distance of eight centimetres. When the pastille has taken the tint B of the radiometer the operation is finished." For the protection of the operator Sabouraud incloses the tube in a metal case lined with ebonite and with an opening towards the patient through which the rays pass. The opening can be fitted with cylinders of various diameters but of uniform length. The area of the scalp to be treated rests in front of the open end of the cylinder. Regulating tubes are used and they are maintained at an equivalent sparking-length of from nine to ten centimetres (four inches). Midway between the scalp and the centre of the tube, in a special opening in the metal case, is placed a platino-cyanide of barium pastille. The current is then passed through the tube until the colour of the pastille matches the standard tint. The exposure is then discontinued. If the patches are few in number they are exposed separately. If they are many and scattered the whole scalp is exposed. This is done by exposing as large a circle as possible, afterwards covering it with a lead shield which exactly fits the area and proceeding over the scalp in the same way until the whole surface has been exposed. The pastille must have behind it a metallic shield which the rays will not penetrate and it must either be wrapped in black paper or the exposure must take place in semi-darkness since the original colour of the pastille is rapidly regained under the influence of daylight.

With my own cases I have been accustomed to use a shield of lead foil with a hole corresponding to the area to be exposed placed on the patient's head. The head is fixed at the proper distance from the tube by means of a simple headrest attached to the chair back. The tube may be covered with a light composition shield in order to protect the operator but the aperture through which the rays pass must be considerably larger than is usual in the shields in general use. The pastille is fixed at three and a half inches from the anticathode (or centre of the tube) and this latter point at seven inches from the scalp. A current of five ampères is passed through the primary circuit (the voltage is 24 units, part of which works the mercury interrupter). The tube is hardened by passing the current through the accessory bulb until it has an alternate spark of four inches. It is found that a current of about 0·3 milliampères is registered by the milliampèremeter in circuit with the tube itself. After ten minutes' exposure the pastille is examined and if not sufficiently dark it is replaced. The exposure usually under these conditions occupies from about 12 to 15 minutes. If the tube becomes softer, which is at once indicated by the galvanometer registering a greater milliampèrage through the tube, the exposure must be longer. With a tube of one inch and a milliampèrage of one milliampère it may even be as long as 35 minutes.[5] But the pastille will indicate exactly when to cease the exposure. After the exposure nothing is done beyond the daily application of a weak ointment of ammoniated mercury with the view to prevent spreading when the hair begins to fall. This occurs with the utmost regularity *during* the third week after the application, beginning usually on the fourteenth day. If, however, the exposure has not been sufficiently long to produce the standard tint in the pastille, depilation will be incomplete, while if the pastille is made too dark by a too long exposure there is danger of subsequent dermatitis. A little practice enables one to recognise easily the proper tint.

In the treatment of cases where the whole scalp needs depilating I at first found great difficulty in adjusting the lead shield so that no two areas overlapped and that no untreated patches were left between the exposed areas. I

FIG. 1.

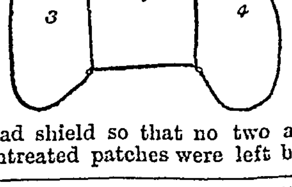

FIG. 2.

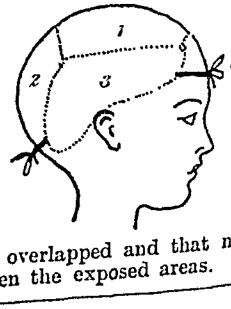


---

[3] Most of the applications in this first series of cases were made by Mr. A. T. Marshall (then house surgeon to the Paddington Green Children's Hospital), to whose patience and skill the favourable results were chiefly due.

[4] While at the time of writing this I was of opinion that the readings of the milliampèremeter and the knowledge of the spark-length of the tube afforded a valuable check upon the information derived from the use of the pastille, I have since found that these measurements are not at all to be relied upon. Apart from the degree of exhaustion of the tube and the amount of current actually passing through it there are other uncertain factors which modify considerably the amount and quality of the rays emitted. Two of these factors are possibly: (1) the age of the tube altogether apart from its degree of exhaustion; and (2) the state of the atmospheric pressure or of the degree of moisture of the air (on a wet day the necessary time of exposure with any tube is found to be much shortened). But whatever the other conditions I have always found the colour change of the pastille a perfectly accurate measure of the therapeutic activity of the rays emitted.

[5] Cf. preceding footnote.

have recently overcome this difficulty by using a light frame of very fine wire so as to divide the scalp into four areas—viz , the vertex, two lateral and the occiput The framework being adjusted the line of the wires is marked on the scalp with a skin pencil so that their position may be kept constant It is then easy to surround each area to be exposed by sheets of lead foil folded round the wires The frame is made simply of three pieces of wire, as in Fig 1, and is fixed by tying with tapes at the nape and across the forehead, as in Fig 2, thus dividing the scalp into four segments Up to the present time I have treated 40 cases by Sabouraud s method, giving in all 100 exposures with the pastilles In every instance[6] the hair has fallen regularly and completely during the third week, leaving the surface quite bald and free from both diseased and healthy hairs Many of these scalps have not yet had time to recover their growth of hair but in those in which the defluvium took place more than six weeks ago the hair has begun to grow again and in all the earlier cases (both with and without the pastille) the hair growth has attained its normal condition In fact my results are in accord with Sabouraud s statements that the hair begins to grow again six weeks after the defluvium is complete and that it is fully grown at the end of three months

Provided then that the proper precautions are taken—(1) that the length of exposure is not allowed to exceed the limit set by the right use of the pastille , (2) that no area or part of any surface is exposed more than once , and (3) that the part exposed is kept at the proper fixed distance from the anticathode of the tube—there is no danger of permanent baldness or injury to the tissues At the same time care must be taken that the exposure is sufficiently long or the fall of hair will not be complete and many diseased stumps will be left behind, requiring needling or other treatment afterwards When a part only of the scalp is being treated *the remainder must be anointed frequently with* a mild parasiticide or the falling hairs from the diseased [illegible] , this is explained by [illegible] be obtained from the [illegible] [illegible]ot been killed by the action of the rays

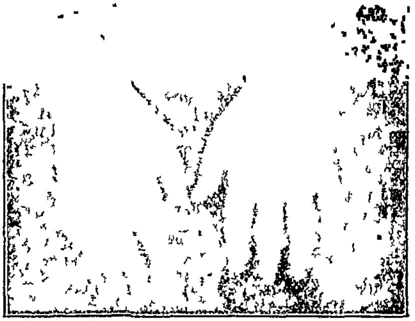
In conclusion, there can be little doubt but that the method of treatment by the x rays is about to supersede all other methods now that, with proper care the risks of burning or of permanent baldness are no longer to be feared The period of infectivity from the time that the patient comes under treatment—i e , from the time of exposure to the completion of the defluvium—is reduced to three or four weeks Even if the cure be considered to be effected only when the normal growth of hair has taken place the length of time under treatment is not more than three or four months In the words of Sabouraud 'La teigne se guérissait en deux ans elle se guérit en trois mois '

Weymouth street W

A CASE OF POLYARTICULAR "QUIET EFFUSION"

BY THOMAS BATTERSBY JOBSON, M D DUB , D P H R O P S LOND

THE subject of these notes, for which I cannot think of a better heading than the above, was a female, aged 24 years For over a year she had been under my care for symmetrical effusions of the knee, the wrist, and the first phalangeal joints of the hand, and, as this subject has lately been brought into prominence by Sir William Bennett a short account of the case may be of some interest With regard to the family history, although there was no history of swellings similar to those from which the patient suff [illegible] of rheumatism Her [illegible] and heart disease in [illegible] rheumatism An aun [illegible] previous history of the [illegible] severe headaches and f [illegible] she remembered was when she was nine years old Her wrists became greatly swollen, so much so that her friends thought she had put them out of joint The medical attendant ordered them to be wrapped in flannel and called her disease "rheumatism " The joints remained big for a long time and to the best of her recollection this attack occurred during the winter At the age of 11 years her knees became affected in the same way , they swelled but she suffered no pain and but little inconvenience Soon after this the first inter phalangeal joints of the hands became enlarged—all five joints of each hand just as they were last year when the photograph here reproduced was taken All these swellings occurred in the winter time, *sometimes not coming on till as late as Christmas, but regu*larly subsiding with the onset of summer, when practically no trace of any enlargement remained Regularly winter after winter these joint effusions recurred with more or less severity till she became quite accustomed to their yearly appearance and did not consult a medical man Occasionally joints other than those mentioned above were affected The elbows were a little swollen on one or two occasions Once she suffered from pains in the back and her mother told her that she had swellings down the spine The ankles were never enlarged, even to a slight degree Until she was 20 years of age the patient felt but little inconvenience from these annual attacks but for the last four years she had been troubled with a considerable amount of stiffness and it was this that by incapacitating her from work, caused her to seek medical advice Also for a few years a considerable amount of dyspnœa on exertion had accompanied the joint swellings During the summer she could walk and run up stairs without getting out of breath The patient had suffered on and off for years from amenorrhœa, but though she had been treated with benefit for this the joint effusions were not correspondingly improved Also her menstrual troubles came on independently of the season of the year whereas the joint affection occurred in the winter only On the first occasion on which I saw the patient she was hysterical but this was the only time that any tendency to hysteria was noticed by me



I first saw the patient in the winter of 1900 Her condition at that time was as follows Both knee-joints were distended with fluid which readily yielded fluctuation There was no redness, local heat, or tenderness on pressure Great stiffness, both in the knees and in the back, was complained of There was no œdema of the legs and the ankle joints were quite normal The wrist joints were enlarged but not nearly so much as the knees The most striking feature was the symmetrical enlargement of all the first inter phalangeal joints of both hands These looked like a row of ' white swellings ' across the fingers and kept the latter in a state of permanent abd [illegible] the same features as [illegible] appearance can be ob- the [illegible] carpo phalangeal joints tained [illegible] were perhaps a little enlarged but very slightly All the other joints in the body were normal The patient suffered from constipation occasionally and also from indigestion The urinary system was healthy the urine containing no albumin or sugar There was nothing abnormal in the lymphatic system Except the tendency to hysteria the nervous system appeared healthy. The heart was sound and there was no obvious abnormality in the circulatory system, except a slight tendency to anæmia. This, however, was slight, her conjunctivæ were by no means pale, and the general colour of the face was good. The dyspnœa could not be entirely accounted for by anæmia. The specific gravity of the blood as determined by the chloroform-benzol method was from 1050 to 1055 and this, according to the table of Hammerschlag, gives a hæmoglobin percentage of 70—a figure very little below the average for women, the blood of the female being slightly more hydræmic than that of the male.

---

[6] The only exceptions were three cases in which owing to a break down in the installation the exposure had to cease before the pastille had reached the standard tint

Treatment was as follows. The swellings could be reduced by pressure but they returned as soon as the pressure was removed. Rest in bed had no effect, so after a week's trial I got the patient up, ordered moderate exercise, massage of the joints, and a mixture of iron and arsenic. In spite of treatment no real improvement in the condition of the joints took place till the spring of 1901.

Whether the swellings are due to a neurosis or whether they are caused by some form of arthritis is an interesting point and, personally, I incline to the former view. The present condition of the patient is similar to that described above. During the last winter, 1904–05, she had no swellings till March when her knees were again attacked.

The interesting points in the case may be recapitulated: the multiplicity of joints affected and their peculiar selection; the annual recurrence of the affection during the winter; the early age at which it commenced before menstruation; and the persistence of the effusions in spite of the menstrual functions being successfully treated.

NOTE ON A CASE OF ANEURYSM SIMULATING DYSPEPSIA.

By R. H. CORDNER, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a man, aged 35 years, was admitted to the hospital complaining of "indigestion." He stated that for two years he had suffered from pain, usually coming on five or ten minutes after food and lasting for an hour or more. The discomfort was lessened by care in the selection of his diet but pain never quite left him and for some time previously to his admission he had restricted his diet almost entirely to fluids. The patient was a thin, worn man with a drawn, anxious face. The odour of his breath was heavy and his tongue was coated. His teeth were few and bad and he wore a plate of false teeth which he stated were not comfortable. His skin was inelastic and his bowels were constipated. His heart and lungs were sound and there was no history of syphilis.

On examination some pulsation was visible in the epigastric notch and extending over to the left of the middle line. On deep pressure over this area a sense of resistance was made out but no definite tumour. On auscultation over this region a faint blowing murmur was heard, localised to a space of about the size of a five-shilling piece. It was not heard in the iliac arteries and there was no diminution of the pulse wave. An x ray photograph gave no shadow.

Under treatment, for some time the patient seemed to improve but latterly he complained of the increasing pain both in the epigastrium and in the back. These pains rapidly became worse and often took place at times quite unconnected with food, occurring often at night and disturbing his sleep and necessitating the use of morphine. One night nearly three weeks after admission the patient suddenly died.

Necropsy.—A post-mortem examination showed an aneurysm of about the size of a small pear involving the whole of the cœliac axis artery and the anterior wall of the aorta. It lay on the spine between the two crura, close up to the aortic opening in the diaphragm and partly covered by the posterior wall of the stomach. The splenic artery came right out of the wall of the sac, the cavity of which was nearly filled with ante-mortem clot. The wall of the aneurysm had ruptured and the peritoneal cavity was full of blood. The stomach seemed quite healthy.

The curious point about this case was that almost all the symptoms were referred to the digestive organs, which, I think, were little if at all affected. The bad teeth, coated tongue, and constipation all seemed to point in the same direction. The probable explanation seemed to be in the close relation of the sac to the stomach wall. It is conceivable that food by setting up peristaltic contractions would cause pain and irritation in the sac. Bland and unirritating, easily digested foods, such as peptonised milk, would by causing less peristalsis cause less pain. This latter fact would account for the apparent improvement under careful dieting.

Aldershot.

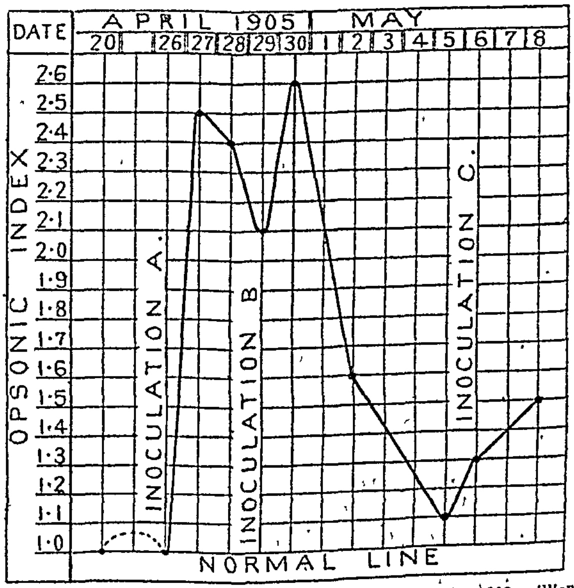
NOTE ON A CASE OF EMPYEMA TREATED BY PNEUMOCOCCUS VACCINE.

By THOMAS GLOVER LYON, M.A., M.D. CANTAB.,

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

THE patient was a man, aged 23 years, of temperate habits. On Feb. 22nd, 1905, Mr. J. L. Lawry (then house physician to the case) resected a rib, letting out two and a half pints of blood-stained inodorous pus. The acute symptoms were at once relieved but the subsequent progress of the case proved unsatisfactory. The patient remained of a bad colour and did not gain strength. The discharge became offensive and constant in quantity, about half an ounce daily. A probe could be inserted four inches into the sinus and provoked coughing. Cultures of the discharge showed a pure growth of diplococcus pneumoniæ and it was determined to try the effect of the inoculation treatment after Dr. A. E. Wright's method.[1] This was commenced on April 26th—i.e., nine weeks after the resection of rib. A record of the details of the injections and their effect upon the opsonic index of the patient's blood will be seen recorded upon the accompanying chart.

CHART OF VARIATIONS IN OPSONIC INDEX.



A, Inoculation 100 millions pneumococci. B, Inoculation 200 millions pneumococci. C, Inoculation 100 millions pneumococci.

Immediately after the first injection a remarkable change occurred in the condition of the patient. He rapidly gained strength and weight and the discharge ceased to be offensive. At the end of a fortnight after the first inoculation the wound had healed and the patient left the hospital on May 10th to resume his ten hours' daily work. It may be added that there was no constitutional or local disturbance attending the inoculations. The temperature, respiration, and pulse remained normal and no trouble arose at the seat of inoculation.

---

[1] THE LANCET, August 6th (p. 411) and Oct. 22nd (p. 1138), 1904.

The bacteriological investigations, preparations of vaccine, inoculations, and determinations of variation in opsonic index were performed by Dr. G. W. Ross, house physician to the case, at whose suggestion the inoculation treatment had been adopted.

Victoria-square, S.W.

A CASE OF LUDWIG'S ANGINA FOLLOWING INFLUENZA.

BY C. ASHLEY SCOTT LEGGATT, M.D. EDIN.

THE patient, a woman, aged 37 years, was first seen on Feb. 21st. She was suffering from tonsillitis of the follicular type usually associated with influenza and of moderate severity. The case ran a normal course and the patient was practically well on the 27th. On March 15th she again sent for me as she had a swelling on the right side of the neck which she thought was due to mumps. She said that she had been fairly well during the intervening fortnight but had not felt quite herself, and first felt pain in the glands of the right side of the neck at a dinner party on the night of the 13th. On the next morning there was a swelling under the right side of the lower jaw but when seen by me on the 15th there was no swelling of the parotid nor was there anything to be seen inside the throat though the patient complained of great pain in swallowing. The temperature was normal but the pulse was rather rapid from the first. During the next few days the patient suffered a great deal of pain but remained in much the same condition and on the 25th Mr. E. Venning saw her with me and advised the removal of a septic molar tooth thinking that it might be the source of mischief. No improvement followed, the pulse increasing in frequency, and the temperature beginning to rise every afternoon to 100° or 101° F., so on the 29th Mr. C. A. Ballance saw the case with me. During this day the pain had been severe and the pulse was 140 and at times slightly irregular, and immediate operation was decided upon. One incision was carried along the anterior border of the right sterno-mastoid and another shorter one was made at the posterior border of the muscle. Scarcely any pus was found but all the cellular tissue was grey-black in colour and gangrenous. The glands, too, along the internal jugular vein were in a state of infective inflammation; some of these were removed. It was then discovered that a coagulum occupied the interior of the jugular vein from the base of the skull to the level of the thyroid cartilage. The vein was divided between two ligatures and the proximal part containing the coagulum was fixed to the skin margin. The patient made a rapid convalescence and in three weeks was able to leave for the seaside.

It is difficult to say whether the tonsil or the carious tooth was the source of the infection of the spreading cellulitis of the neck. Carious teeth or caries of the alveolar process are a well-recognised avenue through which infection of the type of Ludwig's angina may arise in the cellular tissue of the neck. On the other hand, there is no reason why such an infection may not spread from an inflamed tonsil, a condition which has been known to occur in certain malignant scarlatinal cases. In this case the septic mischief in the tooth had been going on for years and probably the supervention of influenzal tonsillitis on the top of this was the immediate cause of the cellulitis. A point of great interest in the case is the thrombosis of the jugular vein which is of great rarity in cases of septic cellulitis of the neck. To this cause may be ascribed the slow onset of symptoms and the absence of severe constitutional symptoms. The blocking of the venous channel was nature's effort to localise the inflammatory process.

Walton-place, S.W.

THE DENTISTS ACT.—At Crediton, Devonshire, on June 14th, Mr. William Baker of that town was summoned for an offence under the Dentists Act of 1878. Evidence showed that the defendant had a brass plate at his house inscribed "W. Baker, surgeon dentist, Limited." The defendant stated that he was a doctor of dental surgery of Chicago, America, and that he had never represented himself to be a registered dentist under the Act of 1878. He was fined £5 and costs. The prosecution was instituted by the British Dental Association.

KING'S COLLEGE HOSPITAL.

A CASE OF ABSCESS OF THE LUNG FOLLOWING GASTRIC ULCER; RECOVERY.

(Under the care of Sir HUGH R. BEEVOR.)

FOR the notes of the case we are indebted to Mr. H. R. Allingham, senior house physician.

The patient, a female, aged 20 years, a domestic servant, had suffered from anæmia with much dyspepsia and constipation during the past two years, occasionally vomiting. On Feb. 24th, 1905, she sought advice for pain in the left anterior axillary line at about the ninth rib. Physical examination of the chest and the abdomen was negative and a mixture containing bismuth was prescribed. On the evening of the 26th, after a full and injudicious meal, the patient was seized with very severe pain in the abdomen, screaming out; she had the pulse of collapse and cold extremities. Morphine was given in repeated doses. Pain was localised to the splenic region with general abdominal tenderness. Next morning the pulse had recovered much, her temperature was 100° F., the abdomen was not distended, but there was no apparent movement on descent of the diaphragm. There were marked hypogastric tenderness and an appearance of menses. During the next two days her temperature rose slightly and leucocytosis was 14 000 per cubic millimetre, and Mr. F. F. Burghard was called in consultation. It was considered that the patient needed watching in hospital and she was admitted into King's College Hospital on March 2nd, 1905.

On admission the patient looked very ill, with a drawn and anxious face. Her temperature was 99·2° and her pulse was 120, of small volume. She complained of severe pain in the abdomen, mostly referred to the left iliac region. On examination the abdomen was slightly but uniformly distended, there was rigidity of the muscles of the abdominal wall, and the abdomen did not move on respiration. There was great tenderness, more marked in the left iliac region. There were slight dulness in each flank, and absence of liver dulness. Some vomiting occurred and constipation was absolute (the bowels not having acted for some days), in spite of the free use of enemata. Immediate operation was considered inadvisable on account of the length of time that had elapsed since the onset of the symptoms and the absence of symptoms localising the suppuration. The abdominal signs continued but did not increase in severity and the distension did not become greater. The pain was as before and the pyrexia ranged from 100° to 101°. By March 6th thoracic signs became evident; dulness was present on the left side from the base of the lung to the fourth rib in the axillary line and over the dull area there was loss of breath sounds, and vocal resonance and tactile fremitus. A blood count now showed a leucocytosis of 18,000. On the 9th exploration of the left chest withdrew two ounces of blood-stained serous fluid; the signs in the chest became more marked and the abdominal signs less evident, though pain continued in the abdomen. The apex beat was throughout in the fourth space, just internal to the nipple line. After the 11th the pyrexia steadily rose day by day with a feeble, rapid pulse (112), the respirations being 36, until on the 16th the temperature reached 104·4°, accompanied by a leucocytosis of 32,600 to the cubic millimetre. The pain became severe and was localised in the left side of the chest and the left shoulder. The physical signs were as before except that the mobility of the abdomen was improved. There was no cough or sputum at this stage. A second exploration withdrew a small quantity of blood-stained serous fluid containing a few cells and sterile on culture. An x ray photograph showed a slight depression and flattening of the left dome of the diaphragm and the area above the diaphragm showed a little opacity on the left side, as of a pleural effusion. The patient became drowsy and apathetic, only occasionally crying out with pain. By the 18th over the dull area tubular breathing and bronchophony were present from the third to the eighth space on the left side, and below the eighth interspace there were signs of fluid effusion as before. During the next few days her general condition became worse, a chronic deafness became more complete, and the pain in the left shoulder was severe, her temperature varying between 102° and 104·4°. Cough appeared on the evening of March 22nd and became frequent and distressing, but there was no expectoration. The pulse was feeble (140) and the respirations were 40. At last, on March 23rd, in the early morning, the patient suddenly brought up, by combined coughing and vomiting, over a pint of fluid. This was chiefly foul pus, with some stomach contents intermixed. At the same time the temperature fell from 102° to 97·4° and the patient was collapsed, with cold sweat, thready pulse (132), and respirations 52 to the minute. Stimulants were freely used and five minims of solution of strychnine were injected hypodermically every four hours. During the next few days the patient continued to cough up foul pus and this did not end for nearly eight days after the rupture of the abscess. The cough was frequent and distressing and great effort produced only slight expectoration. Pain on being moved was acute. On the 25th (two days after rupture of the abscess) signs of pneumonic consolidation appeared at the right base, with pleural frictions, and great pain was felt in the right side. Her general condition was very bad and stimulants were freely administered, combined henceforth with large doses of tincture of perchloride of iron. In view of apparent inability to cough up the pus, &c., emesis was induced with 30 grains of sulphate of zinc, but the result was not satisfactory. By the 29th in very slow stages the patient's condition had improved; the pyrexia, though very irregular, was less; and the condition of the lungs had improved, the right side resolving first. Cough continued very troublesome but expectoration became gradually merely bronchial mucus. Improvement slowly but steadily followed, only interrupted by a thrombosis of the left femoral vein which showed itself in pain and slight swelling of the limb and engorgement of the superficial veins of the leg and the thigh. The temperature did not become normal until so late as May 1st and it has continued so. At first during convalescence the heart's apex moved to the left and there were no normal breath sounds in the left lower lobe. The progress to normal sounds and rapidity of recovery of expansion of the left lung were more rapid than in cases of ordinary pleurisy. The measurement of the left chest is one and a quarter inches less than the right chest. The patient left the hospital practically quite well.

Remarks by Sir HUGH BEEVOR.—In the early days of this illness the symptoms pointed to a subdiaphragmatic abscess as much as a lung abscess, the diaphragm being evidently the site of inflammation. When the Roentgen rays localised the extension of the suppuration as being above the diaphragm any operation was precluded by the presence of serous effusion in the left pleura. In such conditions pneumothorax might have been expected to arise and cause more evil than any benefit to be gained by opening the abscess with such a complication added. But the chief interest in this case lies in the speed and thoroughness of recovery where the abscess was long in penetrating to a bronchus, where secondary pneumonia developed in the other lung, and where the patient was of poor physique. In the face of unsatisfactory results reported in many cases operated upon for pulmonary abscess the experience of this patient seems worthy of notice.

MIDDLESEX COUNTY LUNATIC ASYLUM.—On June 3rd Sir C. Francis Cory-Wright, Bart., D.L., formally opened the new asylum at Napsbury, near St. Albans, Herts. The buildings, which will accommodate about 1200, have been erected under the direction of the architect, Mr. Rowland Plumbe, and it is hoped that the needs of the county will be met for some years The buildings have, however, been so designed as to allow of future development. It is almost needless to say that great attention has been paid to the sanitary arrangements of the asylum and that everything which could add to the well-being and comfort of the patients has been carefully thought out and supplied.

Medical Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—The Onset of Fear and the Onset of Pain in Cardiac Disturbance.—Acute Cerebro-spinal Fever and Intoxication.

A MEETING of this society was held on June 7th, Professor JOHN CHIENE, the President, being in the chair.

Mr. ALEXANDER MILES showed four patients after operation for Acute Generalised Peritonitis resulting from Gangrenous Appendicitis. The patients were boys, aged respectively 9, 13, 16, and 16 years, and were all in the wards of Leith Hospital at the same time during March and April of this year. The cases illustrated the benefit which resulted from washing out the abdominal cavity with saline solution in general peritonitis. Mr. Miles had operated on 45 cases of acute generalised peritonitis associated with gangrenous appendicitis; of these 25 ended fatally and 20 recovered and in all the latter the abdomen had been washed out. Mr. Miles also exhibited a Spleen removed for Traumatic Rupture. The man is now following his usual occupation.

Mr. F. M. CAIRD showed a man after Trephining for Extradural Hæmorrhage. The patient had been found lying unconscious at the foot of a stair. There was only a slight bleeding from the ear and the case seemed to be one of cerebral laceration. A subnormal temperature lasted for three days and suggested a suppurative condition of the brain. The size of the pupils varied from day to day. Seven days after the accident the muscles of the face on the left side commenced to twitch and this soon extended to the arm and leg of the same side. On trephining over the fissure of Rolando on the right side a large, hard, cake-like blood clot, weighing four ounces, was found. Consciousness was regained almost immediately after the operation and though the ability to speak was at first poor it soon regained the normal amount. The patient recollected everything that had happened up to the moment of entering the passage leading to the stairs.

Mr. ALEXIS THOMSON showed a man who had suffered from Tropical Abscess in the Right Lobe of the Liver which had been treated by syphon drainage after the method of Sir Patrick Manson. The exploring needle having shown the presence of pus a large trocar was passed into the cavity in the anterior axillary line and at the seventh interspace and the pus was allowed to escape. A large catheter was then introduced and fixed in, while a tube attached dipped below into a vessel containing boric solution. This form of syphon drainage was established for three weeks, allowing the escape of much thick brown pus. The result was absolutely satisfactory.

Dr. GEORGE A. GIBSON showed a male patient suffering from Ophthalmoplegia Externa et Interna. The affection commenced five years previously in a slight drooping of the right eyelid and had progressively become worse. There was absolutely no movement in the right eye and in the left the superior oblique muscle had alone escaped. There was no alteration in the field of vision; all the cutaneous reflexes were exaggerated. Such cases had been described as superior tabes dorsalis. The disease consisted in a specific affection of the nuclei controlling the nerves of the eyeball.

Dr. GEORGE R. WILSON read a paper entitled "The Onset of Fear and the Onset of Pain in Cardiac Disturbance." The fears referred to were paroxysmal and transient and for the most part nocturnal—such as fear of suicide, fear of disgrace, fear of poisoning someone, fear of mis-signing a cheque, and so on. These symptoms were common in patients suffering from abuse of alcohol and tobacco. The occasion of the dread was probably a transient bradycardia. None of these dreads were of long enough duration to constitute an obsession. With these might be compared the night-terrors of children, nightmare, and the sinking sensation, and the referred pains of cardiac disease. Head's explanation of referred pains was convincing so far as it related to the sympathetic and dorsal mechanism. The primary symptom in all the above experiences was a general and more or less acute sense of uneasiness. Then followed a quick conscious effort at localisation. Both these phases and the subsequent result—a pain or a fear—should be discussed not only as mental processes but as a continuous nerve movement and as [illegible] listribution. With regard to such [illegible] aentioned it might be safely inferre [illegible] mechanism for them having well-defined connexions with the bulbar, sympathetic, and spinal mechanisms. There could be no doubt, for instance, that in the normal man there was a well-established mechanism to represent a sense of danger and that it was closely associated with the mechanism of general uneasiness which was stimulated *so frequently in* bodily diseases. In certain cases the route of the impulses from the cardiac plexus would be through the sympathetic fibres to the dorsal segment, thence to the medulla, thence to the cortex. From the mechanism for general uneasiness the route would be in some cases back to an overstimulated spinal segment where it was intercepted and *sent back again to the cortical mechanism representing*, say, the left arm, and there occurred in the intelligence a "referred pain" in the arm. In other cases a similar impulse from the cardiac plexus, after leaving the mechanism of general uneasiness, was reflected, not to a hyperæsthetic dorsal, but to a hyperæsthetic cortical mechanism and was again reflected to the mechanism of judgment and there occurred in the intelligence a "referred fear." (The term "irrelevant" might be preferable.) In both groups of cases the perversion of the impulse had been determined by a "tender" mechanism—in the one case by a dorsal mechanism which represented a "tender" surface area and in the other case by a cortical mechanism which represented a "*tender*" place in the mind; for, in the cases of transient fear before mentioned, the *fear* referred to some subject of almost constant anxiety. It was not suggested that cardiac disturbance was always the prime factor in these cases of transient terror.—Dr. T. S. CLOUSTON said that all heart pain was not attended [illegible]

[illegible] He called attention to the intimate relationship between melancholia and vascula [illegible] be poisoned *and so* mi [illegible] GIBSON said that in his [illegible] in cases of heart diseas [illegible] could recall many cases of fear, morbid anxiety, &c., in which there was no affection of the heart whatever.

Dr. ALEXANDER JAMES read a paper entitled, "Notes of Cases of Acute Cerebro-spinal Fever and Intoxication occurring recently in Edinburgh and in the Surrounding District Clinically Resembling Forms of Epidemic Cerebro-spinal Meningitis." He said that during the past 15 years he had seen serious and often fatal cases of cerebro-spinal intoxication and fever in which the ordinary causes of such symptoms could be apparently excluded and for the explanation of which some less ordinary infective or toxic agency had to be thought of. Within the past few months he had seen in the Royal Infirmary of Edinburgh and elsewhere a much larger proportion of such cases than usual. He then proceeded to sketch out the most prominent features in a few of the more interesting cases which had come under his observation. One of the patients was a boy, aged 13 years, who was found lying under a tree in a state of unconsciousness from which he could not be roused. He was pale, the pupils were dilated, the pulse was 80 per minute and feeble, his temperature was normal, and there was no paralysis. He had complained of headache previously. A few hours later twitchings of the facial muscles commenced with rel [illegible] supervened. The [illegible] some *hyperæmia* [illegible] medulla; all the [illegible] patient was a male, aged 18 years, who previously to his admission to the Royal Infirmary had suffered from broncho- or catarrhal pneumonia for 14 days. There was also a suspicion that he suffered from typhoid fever but no Widal reaction was obtainable. Examination of the sputum showed many cocci and diplococci but no typical pneumococci. On admission he could hardly be roused to answer questions; his pupils were equal, slightly dilated, and reacted to light, though slowly. On the day after his admission his temp [illegible] pulse and respiration were [illegible] r minute. Attacks resembling [illegible] ow showed themselves about every 20 minutes, with intervals of incomplete relaxation. In these intervals he complained of great pain in the head, neck, and epigastrium, due probably to cramp. Kernig's sign was markedly present; tickling the soles of the feet produced active drawing up of the legs, though knee-jerks could not be elicited. Priapism was present. Lumbar puncture was performed and 15 cubic centimetres of cerebro-spinal fluid escaped readily, indicating high tension. Marked improvement followed, the spasmodic attacks ceased, the patient's mental condition became clearer, and he was able to leave *the hospital five weeks after his admission. The fluid* obtained by puncture was quite clear and contained no organisms. Another patient was a woman, aged 24 years, who, when admitted to the infirmary, complained of great headache and was only semi-conscious; her temperature was 101·4°, her pulse rate was 124, and her respiration rate was 24. Both eyes were slightly prominent, with slight ptosis on *the left side. Kernig's sign was absent*, knee-jerks were present, and the pupils were equal and active. Lumbar puncture was performed and 22 cubic centimetres of fluid spurted out with great relief to the patient's symptoms. She made an excellent recovery. The fluid showed no excess of cells and no organisms. Another patient was a boy, aged eight years, who suddenly fell to the ground, complained of *great pain on the right side of his head*, and dragged his left leg on walking. He became dazed and partly unconscious and seemed paretic on the whole of the left side; his pupils were dilated and only slightly reacted to light. The plantar reflex was more marked on the left side than on the right and knee-jerks were absent on both sides. Four days after his seizure lumbar puncture was performed and *nine cubic centimetres of fluid were withdrawn*. From this time he gradually improved. The fluid contained staphylococcus albus and either staphylococcus aureus or citreus. Two forms of bacilli were also present, the one resembling pseudo-diphtheria organisms and the other being a short bacillus with rounded ends; no diplococci were present.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on June 14th, Dr. J. J. Pringle being in the chair.—Dr. H. Radcliffe Crocker showed a case for diagnosis of a Follicular Eruption occupying the thighs and knees of a woman aged 51 *years. The condition had persisted for six* months. Over the knees the skin was much thickened, reddened, and scaly, and this condition, together with the [illegible] s, inclined Dr. [illegible] rubra pilaris.— [illegible] probably lichen planus.—No other suggestions were offered.—Dr. Pringle showed *another case for diagnosis* of a Follicular Eruption covering the back and front of the trunk of a girl, aged 20 years, who gave the history of the eruption having lasted for five years; it was increasing in extent and was itchy. There was no evidence of seborrhœa or of excessive sweating.—Dr. Crocker, however, considered that it might nevertheless be of the nature of a sweat eruption.—Dr. J. H. Sequeira showed a case of Keratosis Follicularis (Darier's disease) of remarkable extent and severity in a woman who claimed to be of Welsh nationality. The eruption was particularly copious and pronounced upon the upper and inner surface of the thighs, upon the flexor aspect of the forearms and arms, and upon the neck and the abdomen. She had had the disease for from eight to ten years. A *section from the* affected skin was shown and the characteristic dilatation of the orifice of the pilo-sebaceous follicles by plugs of horny material was well marked. This case being only the second example of this rare disease which had been recorded in this country excited a great deal of interest.—Dr. Arthur Whitfield showed a case of Myoma Cutis in a man about 40 years of age. Numerous small tumours were grouped, somewhat like herpes, in the course of the cutaneous division of the right supra-orbital nerve. They were entirely painless, were found only in the position named, and had persisted for five years. It was a moot point whether they had appeared in the site of a previous eruption of herpes, a supposition supported by a history of original "blisters" in this position and by the very anomalous arrangement of the lesions. A section from one of the tumours was shown *at the meeting* and demonstrated that the tumour was undoubtedly composed of unstriped muscular tissue.—Dr. E. G. Graham Little also showed *a case* of Myoma Cutis in a woman, aged [illegible] who had small tumours of the size of a pea upon the neck where they had appeared in the first instance, upon the left arm and forearm, and upon the back of the shoulder. She had noticed the earliest of these about six months ago. They were perfectly painless and she suffered no inconvenience whatever from them, but they appeared to be getting larger and some fresh ones were still coming out. A microscopical section from a tumour on the neck showed characteristic muscle fibres in the deeper parts of the corium, massed together and constituting the greater part of the swelling.—Mr. George Pernet showed a microscopical specimen of Streptothrix which had been derived from a patch of Actinomycosis of the Skin from a case under the care of Dr. Crocker who explained that the patient had been an engineer who had possibly contracted the disease in West Africa where he had also contracted malaria.

MEDICO-LEGAL SOCIETY.—The terminal meeting for the session of this society was held on June 6th, Dr. F. J. Smith being in the chair.—Dr. W. Wynn Westcott read a communication on Suicide. Inquest juries only found about 1 per cent. of suicides guilty of *felo de se*; cases where no evidence was obtained as to the mental condition were regarded as temporarily insane. Patients were often prematurely discharged from asylums and the exigencies of home life led them to slay themselves. Alcoholism was the most common predisposing cause, then the presence of disease. An additional grievance or an overmastering passion was usually the proximate cause of the fatal act. The relation of the sexes was very consistent, three men to every woman. The rate of suicide per 1,000,000 of the population was constantly increasing; thus it was in 1861, 66; in 1881, 77; in 1891, 85; in 1901, 96; and in 1903, 105.—Dr. F. S. Toogood had never witnessed the fear of death in patients dying in the Lewisham Infirmary. Alcoholism, love affairs in the case of women, and the delirium of acute disease, were responsible for most attempts at suicide.—Dr. S. B. Atkinson instanced Sir Samuel Romilly as a case where an effective blood-letting led to speedy regret at the act of self-slaughter.—Dr. James Scott stated that few of those who came under him in Brixton Gaol for attempting to commit suicide could be regarded as insane. He had found that fewest of these cases were entered in February and most in July or August.—Mr. A. E. C. Franklin of the Federated Malay States instanced cases where pity, *ennui*, and even a desire to annoy had led Tamils and Chinese respectively to slay themselves.—Miss E. L. C. Appel, M.B., then read a paper on Feeling and Emotion, their Bearing upon Crime and Insanity. Self-responsibility was a purely human characteristic; to regard criminals as irresponsible robbed them of their manhood. Sensation was the function of the central nervous system; feeling of the sympathetic system. In man evolution especially concerned nerve structures which were influenced by the environment; hence remedial homes of detention were preferable to prisons for criminals. Further, in states of nervous fatigue, ill-health, and even sleep, acts might be performed which would be reprehensible at other times; the actors were not insane but were acting subconsciously. Attendants at public institutions should be chosen with great care, with a view both to watch the behaviour and to influence those committed to their charge.—Dr. Albert Wilson held the view that there was no such thing as free will; a man's impulses and desires were summed up by his intellect and called his will.—Mrs. Saunders Jacobs, B.A., distinguished the semi-conscious from the subconscious state; the brute creation at times manifested a sense of responsibility. Sensation was at the root of every faculty of the mind.—Miss Appel, in reply, said that our wills were bound by our past and to that extent were not free; we should try to improve the mental machine as it was being made in the young.

SAMARITAN FREE HOSPITAL FOR WOMEN, LONDON.—The new out-patients' department and nurses' bedrooms at this hospital were opened on June 14th by Lord Leigh, the president of the hospital, in the absence of Lord Portman, who was to have done so but who had been called to Windsor. It was now desired to instal the electric light and to erect a modern theatre to complete the hospital and a special appeal fund has been organised which will be glad to receive subscriptions. Communications should be addressed to Miss D. Royde-Smith, secretary of the Special Appeal Fund, at the hospital, Marylebone-road, N.W.

Reviews and Notices of Books.

Modern Methods of Treatment: The Open-Air Treatment of Pulmonary Tuberculosis. By F. W. BURTON-FANNING, M.D. Cantab., Physician to the Norfolk and Norwich Hospital; Honorary Visiting Physician to the Kelling Open-Air Sanatorium. London, Paris, New York, and Melbourne: Cassell and Co., Limited. 1905. Pp. 176. Price 5*s*.

THE benefits of the open-air treatment are now generally recognised. Although there are certain advantages, both from a curative and an educational point of view, to be obtained by residence in a regularly constituted sanatorium, nevertheless the treatment can be perfectly well carried out in private houses. In agreement with some other authorities Dr. Burton-Fanning maintains that the conditions which are absolutely necessary for the satisfactory adoption of the open-air system are to be found almost everywhere outside our cities. We regard this statement as rather too sweeping. The site of the building in which the treatment is to be carried out has to be selected carefully in regard to shelter from prevalent winds and a dry soil is obviously better than a moist one.

The early chapters of this book are occupied with certain etiological and clinical considerations and allusion is made to the differences in tractability to treatment which distinguish the various forms and stages of pulmonary tuberculosis. The importance of the early recognition of the disease is duly insisted on, for the success of the treatment is more dependent on the case being taken in hand at the very commencement of the malady than on any other one point. The remarks on this subject are well worthy of perusal. If there are found the assemblage of signs and progression of symptoms characteristic of pulmonary tuberculosis no difficulty will be experienced in arriving at a diagnosis, but certain symptoms may precede the physical signs or the latter may be anomalous and then grave doubts may arise which will be the cause of considerable anxiety to the practitioner.

In the chapters devoted to a consideration of the details of the open-air treatment the routine generally adopted in the case of a patient who is just embarking on such a course is first described. One of the principal points discussed is, Should the patient be wholly confined to bed or should he be allowed up for the whole or part of the day in the bedroom or out of doors? The answer to this question is chiefly supplied by the observation of the patient's temperature, but other points have also to be observed, more especially the rate of the pulse and the condition of the digestive system. Dr. Burton-Fanning's observations on these and other matters afford much valuable information and will greatly help those practitioners who have had no practical experience of sanatorium life. The treatment of the convalescent patient is equally well discussed and the daily routine is carefully laid down. The chapter on diet in the treatment of pulmonary tuberculosis is also a valuable one. Dr. Burton-Fanning objects to the "over-feeding" which was once in vogue. In this opposition we believe he is right. Success in sanatorium treatment depends largely on "individualisation"—that is to say, each patient must be studied separately and "is a law unto himself." Particularly is this the case in regard to diet; we agree with the author when he says: "Our object in the dietetic treatment of pulmonary tuberculosis is to bring the patient's nutrition up to a standard which is judged to be consistent with the highest level of general health and at the same time to improve digestion and assimilation." This can only be done by placing each patient on such a diet as he can properly digest and assimilate.

Another matter that has been too much lost sight of in the past is rightly emphasised in this work—namely, that the majority of the inmates of a sanatorium require life-long care and assistance if their recoveries are to be maintained. This is a subject that naturally bristles with difficulties and is at present receiving a good deal of public attention.

Dr. *Burton-Fanning* adduces some arguments in support of the contention that not only are elaborate buildings unnecessary but that they provide less efficient treatment than more primitive forms of accommodation. There is much to be said in favour of this suggestion when the patients to be dealt with are limited in number, but when upwards of a hundred have to be treated in the same sanatorium then we believe that the administration will be greatly aided by adopting the block or pavilion system.

A System of Practical Surgery. By Professor E. VON BERGMANN, M.D., of Berlin; Professor P. VON BRUNS, M.D.,
of Tübingen; and Professo
Translated from the Gerr
BULL, M.D., Professor of
and Surgeons, New Yoı
Norgate. 1905. Five volun
the text and 102 full-page plates in colours and monochrome. Pp. 4174. Price: extra cloth, £6 6*s.*; half leather, £7 7*s.*; half morocco, £8 8*s.*

THE mere statement of the number of the pages of this system of surgery will of itself suffice to show the elaborate nature of the work. More than 4000 pages of text and more than 2000 illustrations should surely be sufficient for the thorough description of the practice of surgery. The work in its German dress is well known to medical science throughout the world and it was therefore with no small degree of interest and curiosity that we turned to this presentment of the treatise. This is not merely a translation from the German; the work has been edited by Dr. Bull after the translation had been made from the revised second German edition, and the translators are all men of recognised position in surgery and they have added descriptions of methods of practice preferred by English or American surgeons, so that we have the benefit of these additions to the original work. The editor has done his work so well that the new matter has been thoroughly incorporated with the old and the two can rarely be distinguished the one from the other. For this reason we shall not attempt to discriminate between the original and the added matter in the criticisms which we may have to make.

First, as to the translation; it has been well executed so that it is generally difficult for the reader to recognise that he is reading a translation. There is, however, one matter with regard to which we must take exception. In many sciences, although the corpus of the science is identical in all the countries of the civilised world, the names in use in that science may differ considerably, and to this general rule the science of surgery is no exception. Many terms and expressions which are to be met with in surgical treatises in German are almost meaningless in the ears of an English surgeon unless he has an acquaintance with German surgical literature. We will give some examples of what we mean. Fig. 124 is entitled "Struma in Graves' Disease." What will most English-speaking surgeons understand by this? They will not know that in German "struma" is used for enlarged thyroid, seeing that the word is never thus used in English. Again: "If in a double cleft the union has occurred with a short philtrum, a marked shortening in the centre of the lip is the result." To the average reader what idea will the word "philtrum" give? Deficiencies of translation such as these are blemishes which could easily have been removed by the exercise of a little care. There are many real slips which mar the pages of the work. For instance: "The most important thing about this method, [taxis] is that it should not be fractured too energetically." Then we find the expression "labium majora." Again, "If the partitions between the two halves of the allantois fails a double bladder will be the result." Here the meaning may be guessed but the wording is at least curious. We are also informed that "unlike tuberculosis syphilis of the testicle is usually situated in the testis." We do not dispute this fact at all but its statement seems somewhat unnecessary. Of course, the real meaning is that tubercle attacks the epididymis while syphilis attacks the body of the testis. We have quoted these errors not to find fault with the work itself, which is deserving of the greatest praise, but merely to point out that a little extra revision would not have been misplaced.

We will now examine a few of the statements of the book with which we do not agree. In the description of the treatment of enlarged prostate no mention is made of the modern operation of the enucleation of the prostate through a suprapubic cystotomy wound. This is an important omission, for in this country at least this method of treatment is rapidly replacing all others. The origin of varicocele is still referred to the fact that the left spermatic vein enters the left renal vein at a right angle; and the author somewhat mysteriously adds "the pressure in the vena cava is distinctly less than that in the left inguinal vein," though what this has to do with the matter is entirely beyond our comprehension. Two other reasons are also given for the greater frequency of left varicocele: the fact that the left testis hangs lower than the right and that the left cremaster muscle is more stretched and less powerful than the right. These are very inadequate causes. The main reason is the pressure of a distended sigmoid flexure on the left spermatic vein.

In the section on the Diseases of the Mammary Gland we find the following sentence: "Kocher's report of eight cases in which the cancerous nodules of the breast were only partially removed shows how careful one should be in judging of the value of these statistics; six of these showed no signs of recurrence after three years." It is possible that this is only an error of the translator and that the author wrote that only the cancerous nodules were removed. As it reads now it can only mean that portions of the malignant growth were left behind, and yet recurrence took place in only 25 per cent. of the cases.

With a notice of one very striking passage we will conclude. In the account of the treatment of cleft palate we read, "although Wolff has shown that the operation may be performed still earlier, even in the first month of fœtal life......." We must acknowledge that we have never heard of the operation being performed at this early age and we should be glad to receive information on two or three points. In the first place, how is the diagnosis of a cleft palate made within the first month of fœtal life? secondly, is the operation done suprapubically or per vaginam? and thirdly, what is the prognosis for the mother and child? We may also mention that we were under the impression that the union of the two halves of the palate did not commence till the eighth week of fœtal life and therefore an operation for the closure of the cleft within the first month might often be supererogatory. A consideration of the size of the embryo at this early age does but serve to enhance our admiration of the skill of the operator. In the words of Goldsmith, slightly modified, let us add: "And when he next doth perform this operation may we be there to see." We would not have it thought that the passages which we have criticised are typical of the whole work. With the treatise generally we are well content and we regard it as a valuable exposition of modern surgery.

The main characteristics of the System are the fulness with which the subjects are treated and the wealth of illustrations. Many of these are in colours and are very successful examples of colour-printing. The vast majority of the articles are very good but we desire especially to praise those on Injuries of the Head and Diseases of the Breast.

The Preparation and After-Treatment of Section Cases. By W. J. STEWART MCKAY, M.B., M.Ch., B.Sc. Sydney, Senior Surgeon to the Lewisham Hospital for Women and Children, Sydney. With 10 plates and 134 drawings. London: Baillière, Tindall, and Cox. 1905. Royal 8vo, pp. 672. Price 15*s.* net.

To every surgeon the preparation and after-treatment of his abdominal cases must be a matter of the utmost importance, but whether the subject is so important as to warrant a volume of 672 pages being written about it may well be questioned. We cannot but admire the painstaking care with which Dr. McKay has compiled this book and it undoubtedly contains a great deal of most valuable information. The author, as he truly says in his preface, has set down anything and everything that will be a help to the young surgeon. The result is, as he himself admits, that the work has assumed undue proportions, yet there is but little we would wish to see omitted. Acting on the advice of the late Mr. Lawson Tait the author made himself acquainted with the work done in many of the clinics on the continent and he has embodied the knowledge thus gained in his work. The first 19 chapters are devoted to an account of the preparation of the patient, the sterilisation of instruments and dressings, the furnishing of theatres, and other details of antisepsis and asepsis. The next ten chapters are concerned with the after-treatment of the patients and the conclusions to be drawn from observations on the pulse, temperature, tongue, and so on, while the rest of the work deals with the various complications which may follow an abdominal section and their treatment.

In the chapter in which the fitting out of an operating room is considered stress is laid on the many advantages of moveable wash-hand basins over fixed ones. This is really an important point and even at the present time modern theatres are fitted with fixed hand basins which are almost impossible to clean and which can never be sterilised. The different methods of sterilising catgut are described at considerable length. The author acknowledges that he has lost a case from the use of this material and yet he appears still to employ it. For our own part we do not think that its advantages counterbalance the great difficulties experienced in completely sterilising it. Dr. McKay uses gauze sponges but he does not mention the very useful and safe method of using sterilised gauze as sponges in rolls sufficiently long to prevent their being lost in the abdominal cavity. Many operators now always use these in abdominal surgery. For disinfection of the hands the author recommends Lockwood's method of employing a solution of biniodide of mercury in spirit. He is strongly in favour of rubber gloves.

The part of the book which we consider most valuable is that dealing with the after-complications of abdominal sections. Dr. McKay has made a point of very carefully watching his cases and his descriptions of the symptoms, diagnosis, and treatment of those dreaded sequelæ severe shock, hæmorrhage, septic infection, and peritonitis are particularly good. Other chapters, too, which bear evidence of the author's accurate powers of clinical observation are those on the tongue, the pulse, the temperature, and the respiration. Dr. McKay has come to the conclusion that the only purgatives of any value in the treatment of cases of abdominal section are calomel, elaterium (best combined with the calomel), sulphate of magnesium, croton oil, and castor oil. He suggests the fact that calomel so often fails to act by itself is due to the great care with which it is manufactured at the present day. When the cheaper varieties containing some sublimate are employed it acts much more effectually. Schmiederberg, further, has pointed out that calomel acts chiefly on the intestinal ganglia and these are often partially paralysed and difficult to stimulate, especially in cases of shock or peritonitis. Dr. McKay finds that a combination of three grains of calomel and two grains of pulvis elaterini compositus acts most efficiently. In the treatment of the wound after removal of the stitches the mortise and tenon method of applying strips of plaster is described but nothing is said of the much better and more efficient plan of applying a many-tailed binder of strapping completely round the abdomen.

In discussing ileus and pseudo-ileus the author states that he believes, in contradistinction to Treves and others, that if even a small annular section of the bowel loses its contractility it is capable of acting as a complete obstruction to the passage of its contents and so an ileus or a pseudo ileus may be produced. He maintains that since true peristaltic contraction is a coördinated reflex carried out by the local nerve centres in the wall of the gut, the paralysis of a segment of the gut will prevent that augmentation of contraction above and inhibition of contraction below any point which are necessary before any object in the bowel can be moved on.

Some of the most interesting of the remaining chapters are those on peritonitis and its treatment, post-operative adhesions and intestinal obstruction, foreign bodies left in the peritoneal cavity, and post-operative hernia. The book is one which we can recommend strongly to every surgeon as even the most experienced will not fail to learn something from its perusal.

LIBRARY TABLE.

The Preparation and Mounting of Microscopic Objects. By THOMAS DAVIES. Edited by JOHN MATTHEWS, M.D. Edin., F.R.M.S. London: C. A. Pearson, Limited. 1905. Pp. 214. Price 2*s.*—This is a new edition of a well-known little book, the first edition of which was published in 1863, and it will be found extremely useful to all beginners in microscopy and for general work with the microscope. It is stated in the preface that additions have been made in order to extend "the usefulness of the book to a new class of readers—the medical student and the junior medical practitioner. To this end, besides other matter, a brief prefatory chapter has been added embracing the elements of preliminary histological manipulation." The references to blood and method of staining, for example, are, however, too brief for the purposes of the present-day medical student, while the biologist and the histologist will naturally refer to larger works. On the other hand, the book contains almost everything which the general, as distinct from the particular, student of microscopy may desire to know, and several useful suggestions are given for the improvising and making of home-made accessories. There are a good index and a few illustrations. So much excellent matter is provided at a low price that it is, perhaps, ungrateful to ask for more, but the addition of a chapter on the microscope itself would have made the book of still greater practical value.

Handbook of Travel-talk: Being a Collection of Questions, Phrases, and Vocabularies in English, French, German, and Italian. Nineteenth edition. London: Edward Stanford 1905. Pp. 688. Price 3*s.* 6*d.*—This small volume is intended as a pocket companion for ready reference and in apology to scholars the preface says at the outset that "even a scholar, who is able to read foreign works with tolerable facility, may find himself at a loss when he comes to attempt the colloquial phraseology of the roadside or the terms belonging to any particular art, science, or profession." The truth of this remark is well known to any of us who, with an academical knowledge of the language, have *attempted to travel in a foreign country.* The handbook is replete with information upon all practical points and quite up to date, a section having been added especially dealing *with motoring*. *In this* connexion the phrase, "I see a policeman; go slowly," is decidedly significant and proves that the salutary police-trap does not exist only on the *Brighton and Bath roads. The* book would be a most useful companion to any English traveller on the continent. By the way, why is develop twice on one page spelt with a terminal "e"?

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—The June number opens with an address by Professor J. Chiene dealing with the origin of tumours which he attributes to developmental defect—an excess of "maternal influence," the exact meaning of which is not very clear. An interesting paper on the Medico-Legal Relations of Intemperance is contributed by Dr. Stanley B. Atkinson, barrister-at-law. Mr. O. Ernest Pronger sets forth views similar to those recently urged by him in our columns (THE LANCET, June 10th, 1905, p. 1573) as to the far-reaching effects upon health of errors of refraction and gives notes of some cases illustrating this source of trouble. Dr. Walter Ker records certain facts which, in his opinion, tend to throw doubt upon the conveyance of small-pox by the air to districts in the neighbourhood of a small-pox hospital.

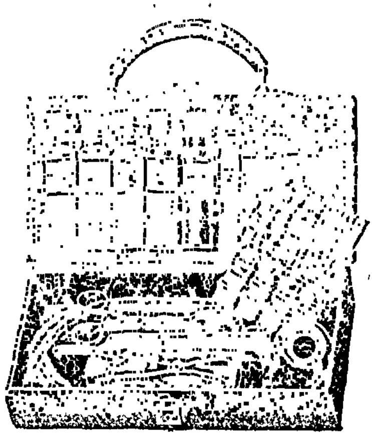
Scottish Medical and Surgical Journal (June).—An interesting address delivered to the Odonto-Chirurgical Society of Scotland by Dr. G. Lovell Gulland upon neuralgia forms the principal feature of this issue. The relation of pain to morbid conditions of the mouth is discussed and illustrations are added showing the distribution of such referred pain in the case of individual teeth. Dr. A. H. F. Barbour narrates a case of climacteric hæmorrhage due to sclerosis of the uterine vessels and refers to the literature of this condition, which is of some importance in that curetting is incapable of effecting permanent arrest of the bleeding and hysterectomy is necessary. Mr. Alfred A. Young records some cases of perforated gastric ulcers in which recovery occurred either with or without operation.

Birmingham Medical Review.—In the May number of this review is contained the first of the Ingleby lectures upon Mentally Defective Children, by Dr. James Kerr. It is full of interest, dealing as it does with conditions leading to defects of speech and of allied functions. The curious condition known as moral imbecility is also alluded to. We hardly think, that the term "ammoral" as a synonym of non-moral has much merit, and we hope that other writers will not be tempted to adopt it. Dr. Alex. Findlay continues his exposition of the application of physical chemistry to medical and biological science and gives some illustrations of the application of the theory of ionisation to explain physiological phenomena. Dr. W. Arthur Foxwell writes a short note upon insomnia, especially that occurring in gouty subjects, and the possibility of treating it in some cases without the administration of hypnotics.

New Inventions.

AN EMERGENCY POISONING CASE.

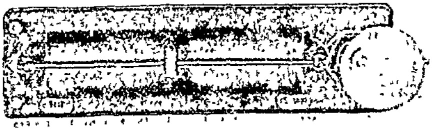
CASES of acute poisoning occur not infrequently in which proper treatment at the time would result in the saving of life or the averting of serious consequences. Ready and effective measures are indicated to obtain satisfactory results in such cases and the general practitioner is sometimes not in a position to take these measures. In order to supply this want I have recently devised an emergency case, an illustration of which is here given. The case is compact and handy and neatly finished in black leather. Its outside dimensions are 12 inches long, four and a quarter inches wide, and six inches high. The contents are as follows: one stomach tube, one tongue forceps, one mouth gag, one two-ounce glass syringe, and one hypodermic syringe. It also contains large bottles of magnesium sulphate, of zinc sulphate in 20-grain powders, powdered mustard, calcined magnesia, and chloroform. The one-ounce vials contain amyl nitrite, alcohol, dialysed iron, acetic acid, oil of turpentine, and aromatic spirit of ammonia. The half-ounce vials contain powdered ipecacuanha, powdered opium, potassium bromide, chloral hydrate, and potassium permanganate. The hypodermic tablets are of strychnine sulphate, morphine sulphate, pilocarpine muriate, apomorphine hydrochlorate, nitroglycerine, digitalis, and atropine sulphate. The case also contains a manual on acute poisoning, giving special symptoms, simple tests, chemical *antidotes*, *physiological antagonists*, and treatment.



New York City. JOHN W. WAINWRIGHT, M.D.

A RHEOSTAT FOR USE WITH THE CYSTOSCOPE.

THE accompanying picture illustrates the rheostat made for me by Mr. Trotter of Glasgow which I have found most useful whenever electric light is available, as it saves carrying secondary batteries. The rheostat works in connexion with the ordinary electric light and is reduced through a 50 candle-power lamp, so that a steady cystoscopic light is maintained without the anxiety of failure which so frequently occurs with secondary batteries. The cost of the rheostat is only 30*s.* and it is easily carried in an ordinary small operating bag. It has been so useful to me that I write this short note recommending it.



J. CRAWFORD RENTON, M.D. Edin.,
Surgeon and Lecturer on Clinical Surgery, Western Infirmary, Glasgow.
Glasgow.

SANITATION AND THE PANAMA CANAL.

THE SOLUTION OF CERTAIN CLIMATIC AND HYGIENIC PROBLEMS.

By John George Leigh.

III.[1]

Many circumstances conspired to lighten the task imposed upon the Health Department in the Panama Canal Zone. Indeed, it is not too much to say that, had they been vested with larger authority and more generously provided with funds, the chiefs of this department could not have been better situated for solving the important problems with which it was, and remains, their duty to cope. There is nothing mysterious or doubtful about the diseases which they are called upon to combat; these have been so closely studied during recent years that there no longer exists considerable uncertainty as to their causes and the best means of treating and controlling them. As a matter of fact, among the medical staff now in authority in the Isthmus are men of world-wide reputation in connexion with these very diseases and tropical sanitation generally. The climate and associated local conditions are noisome, as has been demonstrated, but their worst effects are well understood, and the data available respecting earlier disappointments and failures should now be invaluable as guides and warnings. Most important, however, of all the advantages referred to are those associated with the political conditions ruling in the Canal Zone. One of the leading purposes of the creation of this territory was to secure for the United States authorities ample opportunity for putting in force such sanitary rules and regulations as might be deemed necessary during the construction of the canal, and subsequently, for the preservation of public health. This will be sufficiently demonstrated by the following excerpts from the treaty between the United States and the Republic of Panama, which came into operation early last year:—

> Article II.—The Republic of Panama grants to the United States in perpetuity the use, occupation, and control of a zone of land and land under water for the ...... sanitation and protection of said canal ...... extending to a distance of five miles on each side of the centre line of the route of the canal to be constructed, the said zone beginning in the Caribbean Sea three marine miles from mean low-water mark and extending to and across the Isthmus of Panama into the Pacific Ocean to a distance of three marine miles from mean low-water mark—with the proviso that the cities of Panama and Colon and the harbours adjacent to said cities, which are included within the boundaries of the zone above described, shall not be included within this grant. The Republic of Panama further grants to the United States in perpetuity the use, occupation, and control of any other lands and waters outside the zone which may be necessary and convenient for the ...... sanitation and protection of the said enterprise. The Republic further grants in like manner to the United States in perpetuity ...... the group of small islands in the Bay of Panama, named Perico, Naos, Culebra, and Flamenco.
>
> Article III.—The Republic of Panama grants to the United States all the rights, power, and authority within the zone mentioned which the United States would possess and exercise if it were the sovereign of the territory within which such lands and waters are located, to the entire exclusion of the exercise by the Republic of Panama of any such sovereign rights, power, or authority.
>
> Article VI.—All damages caused to the owners of private lands or private property of any kind by reason of ...... the works of sanitation and protection herein provided for shall be appraised and settled by a joint commission appointed by the Governments of the United States and the Republic of Panama, whose decisions as to such damages shall be final and whose awards as to such damages shall be paid solely by the United States. ...... The appraisal of said private lands and private property and the assessment of damages to them shall be based upon their value before the date of this convention.
>
> Article VII.—The Republic of Panama grants to the United States within the limits of the cities of Panama and Colon and their adjacent harbours and within the territory adjacent thereto the right to acquire by purchase or by the exercise of the right of eminent domain, any lands, buildings, water rights or other properties for the construction, maintenance, operation, and protection of ...... any works of sanitation, such as the collection and disposition of sewage and the distribution of water in the said cities of Panama and Colon which, in the discretion of the United States, may be necessary and convenient. ...... All such works of sanitation ..... shall be made at the expense of the United States, and the Government of the United States, its agents or nominees shall be authorised to impose and collect water rates and sewerage rates which shall be sufficient to provide for the payment of interest and the amortisation of the principal of the cost of said works within a period of 50 years and upon the expiration of said term of 50 years the system of sewers and waterworks shall revert to and become the properties of the cities of Panama and Colon respectively, and the use of the water shall be free to the inhabitants of Panama and Colon, except to the extent that water rates may be necessary for the operation and maintenance of said system of sewers and water. The Republic of Panama agrees that the cities of Panama and Colon shall comply in perpetuity with the sanitary ordinances, whether of a preventive or curative character, prescribed by the United States; and in case the Government of Panama is unable or fails in its duty to enforce this compliance by the cities of Panama and Colon with the sanitary ordinances of the United States the Republic of Panama grants to the United States the right and authority to enforce the same.

It will be evident from the above that so far as treaty rights and authority are concerned the United States Government has everything in its favour, and that there was ample justification for the opinion expressed by Dr. W. C. Gorgas soon after his appointment as head of the health department that the conditions were such that "we ought to be able to get up a model sanitary department," rivalling on a small scale the most efficient and best-equipped of any modern nation. The Canal Zone, or territory immediately under the jurisdiction of the United States, consists of rather less than 500 square miles, with a population, exclusive of the canal staff but including many labourers on the works, of, according to a quite recent census, 9742. Of these people 807 live at La Boca and 540 at Ancon, which may be described as suburbs of the city of Panama; 1393 at Culebra and 933 at Emperador, in the neighbourhood of the great mountain cutting; 668 at Gorgona and Matachin; 723 at Bohio and the small adjacent villages; 555 at Gatun, and 1160 at Cristobal, in the vicinity of Colon. The cities of Panana and Colon, with populations of, respectively, 20,262 and 7214, are equally under American authority so far as health and sanitation are concerned; consequently, if we take into consideration recent immigration (see Table V.) and the probable demands of contractors and engineers it may be anticipated that a year hence the population along the canal line will exceed 50,000 and possibly even reach 60,000.

Table V.—*Immigration into the Canal Zone and Cities of Panama and Colon from July 1st to December 31st, 1904.*

Month.	Arrivals.	Departures.	Excess of arrivals.

December	2431	1828	603
Totals...	12,056	8414	3642

The French canal companies, it should be remembered, possessed no police powers and were therefore unable to exercise other than moral suasion (a frail reed on which to rely in such a campaign) upon the inhabitants along the canal route to cleanse their reeking villages and to observe the elementary laws of health. All they could do was to devote considerable sums of money to the erection and maintenance of hospitals for the treatment of their employés and occasionally other denizens in the Isthmus. During the first years of its existence the New Company devoted very considerable attention to the improvement of sanitary conditions, but more recently, thanks to its uncertain tenure of the canal property and the disturbed state of the country, its zeal very sensibly abated. Thus it happened that when the control of the enterprise passed to the United States the towns and villages along the canal line were more than normally filthy, while the hospitals were almost completely denuded as regards both staff and supplies. Fortunately there was at that time no prevalent sickness on the Isthmus; during the preceding 12 months there had been a few cases of yellow fever and small-pox, considerable mortality caused by consumption, but no cholera or plague. During the early months of 1904 the total deaths reported in Panama were: in January, 92; in February, 95; in March, 94; and in April, 63. Of these, beri-beri accounted for 16; dysentery for 17; malaria for 11; "fever," unclassified, for 47; tuberculosis for 46; and yellow fever for 4. The deaths from the last-mentioned disease during the years 1901, 1902, and 1903 were respectively 11, 182, and 48, the large mortality in 1902 being attributed to the presence in Panama of many soldiers, non-immunes, from the mainland of Colombia. It was found that in Colon the most common and fatal disease was

---

[1] Nos. I. and II. were published in The Lancet of June 3rd (p. 1530) and 10th (p. 1597), 1905, respectively.

[illegible] and [illegible] discovered, on taking possession of the properties of the canal company, that two of the hospital wards at Ancon were being used by a local society [illegible] with sickness at Panama. [illegible] ir condition and demanded [illegible] and minor alterations to be adapted to modern requirements. Their existing capacity was about 500 beds, but in case of emergency sufficient ward space was available for 200 additional beds. The hospital, which is built on the pavilion plan, is admirably situated, well elevated above the city, and surrounded by beautiful grounds. A less satisfactory report was forthcoming respecting the condition of the company's hospital at Colon, but the work of remodelling and putting into proper repair the various buildings is now, it is understood, complete, as also is the transfer to this institution of a second hospital at Colon heretofore under the control of the Panama Railroad Company. It was believed by the Canal Commission of 1904 that hospital buildings providing accommodation for 300 beds would meet all requirements at the Atlantic terminal of the canal; to-day, however, the situation is of such character as to demand the early erection of another hospital and an expenditure of $40,000 for this purpose has quite recently been sanctioned. Some years ago a large building was erected on the island of Taboga, in the bay of Panama, for the benefit of convalescent canal employés. This has been repaired by the American authorities and will soon, it is believed, be put to its former use.

Scant attention appears to have been paid by the native government of the Isthmus to the care of the afflicted or indigent population. In the city of Panama there is a municipal institution known as the Hospital San Tomas, to the small income of which patients contribute at fixed rates dependent upon their financial position. There is also in the same city an almshouse, the Asilo de Bolivar, with accommodation for about 70 inmates, hopelessly indigent or afflicted with chronic ailments. These buildings were found to be in a very unsatisfactory condition, which, however, has recently been somewhat improved. Up to last year the local government made little or no provision for the care of lepers or of the insane but in accordance with an agreement arrived at in December progress is now being made with the erection of a hospital by the Canal Zone authorities, to which the Republic of Panama may send persons insane or afflicted with leprosy and the indigent sick upon payment of a certain rate per capital. By the same and other agreements the Panama authorities granted to the United States complete sanitary and quarantine control over the cities and ports of Colon and Panama and power to exclude from the Canal Zone and other places under American jurisdiction any persons whose presence may be deemed to endanger the public health or in any manner impede the prosecution of the work of opening the canal.

Among the first acts of the late Canal Commission were the constitution of a Health Department as a sub-department of the Canal Zone government and the selection of two of their number, Mr. C. E. Grunsky and Mr. W. H. Burr, as a special committee on sanitation. It was arranged that the affairs of the department should be administered by a Board of Health of four members—namely, the chief sanitary officer (with authority as executive head of the department), the director of hospitals, the chief quarantine officer, and the chief sanitary inspector of the Canal Zone. Dr. W. C. Gorgas, Colonel, United States army, was appointed chief sanitary officer, with headquarters at Ancon; Dr. John W. Ross, United States Navy, director of hospitals, stationed at Ancon; Dr. H. R. Carter, of the United States Health and Marine Hospital Service, chief quarantine officer; Dr. Louis A. LaGarde, Major, United States Army, superintendent of the Ancon Hospital; Dr. L. W. Spratling, Surgeon, United States Navy, superintendent of the Colon Hospital; Mr. Joseph Le Prince, chief sanitary inspector of the Canal Zone; an [illegible] Dr. A. N. [illegible] of Colon, [illegible] and Dr. L. [illegible]

An engineering force was also organised for the special purpose of designing and constructing waterworks and sewer systems for the cities of Panama and Colon. To supply water to the former it was decided to build a reservoir at the headwaters of the Rio Grande, about ten miles from the city, and thence to convey the water in a 16-inch cast-iron pipe to a distributing reservoir having a capacity of 1,000,000 gallons constructed on the summit of a hill at Ancon. This water-supply system, which will, I understand, be shortly in operation, has been designed on the basis of a minimum supply per diem of 60 gallons per head for a population of 30,000. It is possible that eventually the chief source of supply for both Panama and Colon and the entire Canal Zone between these terminal points will be the reservoir formed by the great dam to be constructed at Gamboa or elsewhere for the purpose of controlling the Chagres floods. A very complete sewer and drainage system, estimated to cost £52,870, has been designed for the city of Panama and considerable progress is reported as regards its construction.

Greater difficulty and delay are involved in the case of kindred works at Colon. This city is built upon a flat sandy island, no part of which is more than a few feet above mean sea level; indeed, considerable portions are covered with water at high tides. Some years ago the Panama Railroad Company built a small reservoir near Mount Hope, about two and a half miles from the city, and from this water of indifferent character has been, and is still, supplied to what may be described as the official quarter of Colon, the remainder of the population having to content itself with rain water falling upon the corrugated iron roofs and buildings and collected in tanks. At the time of the last available report on the subject the problem of a water-supply for Colon seemed yet unsolved. The same must also be said concerning the design of an efficient system of sewers. The difficulties connected with this will probably have to be met by raising the general surface of the town and utilising for this purpose the excavation from the inner harbour constituting the entrance to the canal. Until recently the authorities appeared justified in regarding the delay as of less moment than would have been equivalent troubles at Panama, for Colon, once reputed to be even more dangerous to health than the Pacific city, enjoyed during the years 1893–1904 comparative immunity from infectious diseases and, indeed, quite escaped the yellow fever epidemics of 1897, 1899, and 1900. This has been attributed by Dr. Lacroisade and others to the minor sanitary works executed in the early "nineties," the filling up of the small swamps in and about the city, and the cleaning of streets which formerly were "veritable sewers," and up to last year, in the opinion of a majority of visitors, continued to merit the same description. Whatever be the value of these explanations as regards the past it is now certain that there should be no undue delay in materially improving the health conditions of the city, for, in addition to a general death-rate higher than for many years past, Colon has recently been visited with an outbreak of yellow fever peculiarly fatal to prominent canal employés, among the victims being Mr. Johnson, the chief architect, and Mr. West, the auditor.

It became evident to the United States authorities, immediately after the transfer of the canal property, that their first duty was to protect the Isthmus from the introduction from abroad of infectious diseases, and that this could only be done by acquiring control of the quarantine and strictly enforcing the necessary regulations. At Panama especially the inspection of shipping had hitherto been very lax, nor did there exist any equipment for the disinfection of vessels or isolation of infected cases. Fortunately, the Panama Government raised no objection, and on May 24th Dr. Claude Pierce was appointed quarantine officer for the port of Panama pending the arrival of Dr. Gorgas. It was not, however, until July 1st and 16th respectively that the Commission assumed control of the quarantine at Panama and Colon. A record of the principal work at these ports from the dates mentioned to the close of the year will be found in Table VI, to which might be added a note concerning the sanitary supervision of the hulks and tenders in the harbours and wholesale destructions of rats, by poison, traps, and fumigation.

Apart from the quarantine service and hospital work, to which fuller reference will presently be made, the energies of the Health Department have been mainly directed to improving the sanitary conditions in the terminal cities and along the canal route. This has very properly been regarded as an indispensable duty, preliminary to the introduction of the army of labourers required for the completion of the entei [illegible] can [illegible] for tl [illegible] of work so [illegible]

satisfactory to note that, generally speaking, the native inhabitants are accustoming themselves to the demands of the sanitary authorities and are even giving promise of eventual willing coöperation. The first step to this end has been a strenuous endeavour on the part of the authorities to combat the prejudice against hospital treatment which everywhere seems inseparable from ignorance. Dr. Gorgas found in this prejudice his chief difficulty during the severe epidemic of yellow fever in Havana and that the people at first would take the risk of any punishment rather than report their sick. Eventually, however, the reputation of the hospital overcame this trouble. Concealment of cases became more and more infrequent, until at last the disease was to all intents and purposes absolutely stamped out. There no doubt remain in and about Havana plenty of mosquitoes of the stegomyia variety, but they have had no opportunity during the past four years of biting a human being infected with yellow fever and are consequently themselves entirely harmless.

It is not too much to hope that a similar triumph of preventive medicine over not only yellow fever but also the more widely diffused malaria may attend United States' control in Central America. Dr. Gorgas is here employing (but, as has been shown, under more propitious conditions) the same methods which proved so successful in Havana—viz., a systematic cleaning up of the terrain, a no less systematic and wholesale destruction of the stegomyia and anopheles and their breeding places, and the treatment under screening of all infected or suspected cases. During the past ten years or more there have been many instances—e.g., at Ismailia, in Cuba, on the properties of several of the Gold Coast mining companies, and elsewhere in Africa, under Dr. Koch—of malaria being controlled by destroying the breeding places of the anopheles and so treating the infected human being that he could not poison the mosquito. All these trials, however, have been on a small scale as compared with the experiment now in progress on the Isthmus of Panama, which is practically an attempt to free an entire population from the malarial infection. Not the least satisfactory feature of the enterprise is the fact that Dr. Gorgas has approached the problem hopefully but without any false ideas as to its simplicity. "We shall," he has said, "no doubt, meet with many disappointments and discouragements, and shall succeed in the end only after many modifications of our plans and after many local failures."

The extent to which the natives of the Canal Zone are infected with malaria is demonstrated by a series of interesting experiments (Table VII.) made at Bohio and other villages along the canal line during October, November, and December last. The figures indicate (1) that not fewer than from 50 to 60 per cent. of the inhabitants of the Canal Zone are infected by the malarial plasmodium and that consequently the only essential for new arrivals to contract malaria is the presence of anopheles; and (2) the very positive value of quinine as a destructive agent for the malarial parasite. To the virulent character of the types of malaria endemic on the Isthmus striking testimony is given in Table VIII.

It will be remembered that this paper was prompted by two questions, of which the first had reference to the probable effects of the pernicious climatic and sanitary conditions of the Isthmus upon the vast army of immigrant labour required to complete the canal. The American authorities, including those charged with the health administration, estimated, when they assumed control of the Canal Zone and cities of Panama and Colon, that one year's work would effect such a wholesome revolution as henceforth to warrant the inclusion of the canal region among the most healthy of tropical countries. It is with unfeigned regret that I reach the conclusion that this anticipation has been woefully frustrated, and this I do without depreciating the gravity of the difficulties which it was only reasonable to expect and of others, infinitely more discouraging, caused by false economies, delays in furnishing supplies, and the inherent faultiness of the law under which the late Canal Commission was appointed. That both in the terminal cities and throughout the Canal Zone great sanitary improvements have been effected during the past 12 months no one can deny; but they fail to constitute a situation sufficiently favourable to justify defiance of the enormous hygienic dangers involved in a precipitate inauguration of the ambitious engineering programme to which I alluded in the introductory portion of this paper.

Evidence of the gravity of the task undertaken by the American sanitary authorities may be found in the fact, now generally admitted, that their energetic efforts have not yet effected any appreciable diminution in the Isthmian death-rate or, indeed, in the percentage of the population demanding medical or surgical treatment. This is the more serious because it cannot be pretended that under the existing Commission they possess inadequate powers or are short-handed to any considerable degree. Indeed, the gravity of the situation becomes more marked when one remembers that, thanks to the general cleaning up which has taken place, the systematic draining work in and about the towns, the removal of brush and long grass, the filling in of low and swampy land and other places admirably adapted for the breeding of the stegomyia fasciata, anopheles, and several varieties of culex, the frequent removal of night-soil pails and garbage cans, the inspection and fumigation of infected or suspected premises, and a widespread distribution of mosquito-proof water containers, the entire region must be unquestionably regarded as in a better sanitary condition than ever in its history. Nevertheless, as will be seen from Table IX., concerning the death-rate of Panama, and the following summaries of the work accomplished by the medical and surgical staffs of the Ancon and Colon hospitals and at the emergency hospitals and dispensaries established along the canal line, the hygienic condition of the people could not well be worse.

Patients admitted into Ancon Hospital from May 4th to Sept 30th, 1904, 477, discharged, 159; died 21 Admitted during October, 230 of

From these figures it would appear that during the course of very few months no fewer than 8756 persons out of a total population, allowing for the latest arrivals, of little more than 40,000 found cause to avail themselves of medical or surgical treatment—and this notwithstanding a marked improvement in the health conditions of the country. Later statistics not only signally fail to suggest a more hopeful outlook but even add to the gravity of the situation, for, quite recently, in addition to rising mortality and sickness returns the Health Department has been called upon to face unexpected and alarming epidemics of yellow fever. These visitations should serve to curb the impatience of many Americans concerning the alleged undue delay in commencing on a large scale the work of canal construction. It must now be evident, even to the most confirmed doubter, that yellow fever is still endemic on the Isthmus and that neither Colon nor Panama can be considered reasonably secure from a recurrence of dangerous outbreaks until each is provided with an ample and wholesome water-supply, for,

Of the 125 deaths reported in October 17 occurred in the Hospital San Tomas and 17 in Ancon Hospital. Of the latter ten were of patients sent in from the Canal Zone stations, and should, consequently, in estimating the death rate be deducted, as should also be 14 stillbirths The remaining 101 deaths represent an annual rate per 1000 of 59 80 During November, of the 17 deaths occurring in Ancon Hospital, nine were cases sent in from zone stations Deducting these and eight stillbirths the deaths represent an annual rate per 1000 of 52 70 Deducting six outside cases occurring in Ancon Hospital and ten stillbirths the total for December represents an annual rate per 1000 of 69 816.

pending such improvement, it is obviously impossible to prohibit the use of water containers, the favourite breeding place of the stegomyia mosquito. Nor can it be hoped, until the long-promised waterworks and sewers are in operation, that there will be any sensible diminution in the general death-rate. In view of all the circumstances, and apparently for some time to come, the only possible reply to the first point raised in the present discussion seems to be a direct and unequivocal negative.

In default of immediate and almost heroic measures to develop better sanitary conditions the Canal Commission may shortly find the operations of its engineering and other staffs seriously hindered, not only by difficulty in obtaining additional labour but also by panic among its existing force. Although it should now be matter of almost general knowledge that yellow fever is not contagious in the same sense as is small-pox or scarlet fever, the reported presence of this much-dreaded malady invariably excites an amount of terror quite disproportionate to the actual danger. Reports, no doubt exaggerated, respecting the recent outbreaks on the Isthmus have already produced such effects in Jamaica, Porto Rico, and other potential labour-recruiting fields as materially to lessen the supply of cheap labour arriving from these places. The proposal to get over this difficulty by importing a considerable number of Japanese and Chinese coolies will, it is to be hoped, signally fail, for it is notorious that Asiatics are the most susceptible of any people to yellow fever infection. Within the past few months a remarkable percentage of the Japanese in Panama have been attacked, and it is scarcely necessary to recall to memory the enormous mortality among the Chinese and Indian coolies in the days of the de Lesseps company and during the construction of the Panama Railroad. Even as regards the white employés, recent events have had untoward effects, for, according to Mr. John Barrett, the ex-United States Minister to Panama, himself one of the most optimistic of men concerning the canal, the frequent changes (caused by fear of yellow fever and other illness) among the foremen of all classes, the locomotive firemen and drivers, steam shovel operators, clerks, and engineers, have already much reduced the efficiency of the work accomplished. Unless conditions are improved and wages are greatly increased it is doubtful, says Mr. Barrett, if men of this class can be kept on the Isthmus—"there is no use in obscuring the truth in this respect."

I have left myself but short space in which to refer to the probable effects of the completed canal upon public health, nor indeed is it necessary at this moment to devote considerable attention to the question. Recent events may postpone by many months the recommencement on a large scale of the work of construction, for there is no doubt that in the course of what may be described as the preliminary campaign against climate and disease the American authorities have sustained a regrettable repulse. That they will eventually conquer is equally certain and the more decisive the victory is the more permanent should be its results. In order to insure for the completed canal the confidence and support of commerce its builders must so modify existing health conditions as to deprive foreign ports of legitimate cause specially to mistrust shipping newly arrived from the Isthmus. Even now it is well to remember that there are other places no less notorious for the dissemination of disease. There may be some doubt as to the climatic conditions necessary to propagate yellow fever, but no difference of opinion can exist as to the most favourable local requirements—defective drainage and decomposing organic matter. If supplied with the needful food, in the shape of filth the germs will thrive in spite of quarantine but if starved by cleanliness their development is checked. When, as may be hoped, the United States authorities are able to convince the outside world that, thanks to improved sanitation, yellow fever is no longer endemic on the Isthmus an object lesson will have been provided which should not fail to have widespread influence. With such example of success before them the health officials of ports in the Gulf of Mexico, in Eastern Asia, and on the eastern and western littorals of South America, which are now frequently visited by yellow fever and which by the completion of the Panama Canal will be brought into closer and therefore dangerous relations, may possibly be inspirited to a more comprehensive appreciation of their responsibilities. Thus it may happen that not only may the Panama Canal not endanger public health but even serve as a factor in its general promotion.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 23, 1827.

MAL-TREATMENT OF ASSISTANT SURGEONS IN THE NAVY.

To the Editor of THE LANCET.

SIR,—On a subject interesting to many of your medical readers, particularly those whose object it is to enter the public service of their country, I have taken the liberty to address you; and, as I am convinced from personal experience that many would never enter the naval medical service were they aware of its disadvantages, I hope that the following comparative view of the army and navy medical services will not be unacceptable.

When an assistant surgeon is appointed to a ship, he finds that he is to mess with the midshipmen; and if to a ten-gun brig, he is doomed to eat his meals in a berth about six feet by seven in extent, with from six to nine messmates. This, in a tropical climate, the thermometer ranging from 85° to 90°, is far from being an enviable situation. There is seldom any *scuttle* in the berth to admit air, and at dinner the heat is so excessive, that all are obliged to strip to their shirts. In order to accommodate the captains, and the gun-room mess, the midshipmen are obliged to dine at twelve o'clock, when the heat is greatest. Add to this the privation of fresh meat and vegetables at sea, sometimes for months together, and contrast the navy assistant surgeon's situation with that of the hospital assistant in the army, who sits down to the same mess table with his colonel and brother officers, considered to rank equally with them as a gentleman, dining in a comfortable airy apartment, and enjoying all the luxuries of the shore. For the assistant surgeon in the navy, no cabin is allowed, his place of repose is a hammock;* the lid of his chest must serve him as a dressing-table, and in the open steerage he has to perform all the necessary offices of ablution, &c. Look again at the army medical man, who has his quarters allotted him, with every convenience that can be procured on shore.

It is universally acknowledged, that the sea service is a much harder one than the land, and one would naturally suppose, that compensation would be made to the naval medical man in proportion; but what is the fact? The assistant surgeon in the navy may serve eight, ten, or twelve years before he obtains promotion, and instances have occurred, where the rank of surgeon was not attained until after sixteen years servitude. After all, he finds that only three years of that time will be considered as *servitude*.† Now the army hospital assistant is allowed every hour that he serves. What is the cause of this injustice?

Another thing the naval assistant surgeon has to complain of is, his being degraded to mess in the midshipmen's berth. Surely his education and respectability as a medical man, entitle him to rank with any lieutenant, master, purser, or marine officer in the navy. Why then compel him to mess with unruly boys? He is expected to study, to prepare himself for a second examination; surrounded by such troublesome companions how is he to study? The gunner, boatswain, and carpenter, who have severally risen from the rank of common sailor, are each entitled to a cabin; and yet a medical man is obliged to sleep in a hammock, like one of the lowest rank!

The condition of naval medical men calls loudly for reform, and reform must take place, or the naval service will not be provided with able and intelligent surgeons.

The assistant surgeon should have a cabin, be allowed to mess with the lieutenants, and be entitled to the same advantages of pay as the army assistant surgeon.

To those young medical men whose intention it is to become candidates for the appointment of assistant surgeon in the navy, it is to be hoped that the above observations may be acceptable, and the object of the contributor will be attained.

AN ASSISTANT SURGEON IN THE NAVY.

---

* A hammock is composed of a piece of coarse sacking, suspended at either extremity from the inferior surface of the deck, by bunches of cord called clews.

† See Navy List.

THE LANCET.

LONDON: SATURDAY, JUNE 24, 1905.

The Degrees in Medicine and Surgery of the University of London.

ALL those who are interested in the development of the University of London must experience a certain satisfaction in perusing the reports recently presented to the General Medical Council relating to the final examination for the degrees of Bachelor of Medicine and Bachelor of Surgery. It will be remembered that important changes in the regulations have been effected and the first examination under the new conditions was held last October and was attended by an inspector and a visitor on behalf of the General Medical Council. Perhaps the most important of these changes consists in the fusion of the degree of Bachelor of Surgery with that of Bachelor of Medicine. Formerly only a small proportion of graduates in medicine presented themselves for further examination in surgery and although an examination in surgery formed part of the final M.B. examination it occupied a very subordinate position and neither demanded nor received very much attention at the hands of the candidates. So long as it was recognised that the medical degree of the University of London was concerned primarily and essentially with medicine, in which the standard was certainly high, the surgical part of the examination was allowed to continue at a comparatively low level, with the feeling that those who wished for a higher surgical standard and for a degree in surgery could present themselves for the further examination for the degree of Bachelor of Surgery.

But circumstances recently combined to render the neglect of surgery in the examination for the degree of Bachelor of Medicine very inexpedient. The fusion of the examining boards of the Royal College of Physicians of London and the Royal College of Surgeons of England resulting in a Conjoint Board holding one set of examinations for a pass degree in medicine and surgery directed criticism to the methods of the University of London. The possession of the M.B. degree was a qualification to practise both medicine and surgery but the examination in the latter subject being inadequate placed the graduates in an unfortunate position compared to the holders of the double diploma of the English Conjoint Board. The graduates themselves, conscious of some inequality of the conditions obtaining in London as compared with those of other universities, had the right to feel aggrieved that, despite the work of a really high standard which they were called upon to do, they did not receive the attention to surgery which was given to the students at other centres and by other qualifying bodies. Still the surgical examination at the final M.B. examination of the University of London was regarded as a satisfactory test of knowledge despite a good deal of criticism until 1902 when after inspection it was reported to the General Medical Council by the visitor and inspector appointed under the Medical Acts that the examination in surgery "was not such as would secure the standard of efficiency required by the Council." The examination was then described as being on a distinctly lower level than the examinations in medicine, midwifery, and forensic medicine. Such an opinion necessitated change, even though the Council generously postponed consideration of the report of the Examination Committee. If the standard was to be raised to that of medicine there could be no reason for maintaining the separation of the degree of surgery from that of medicine, and the decision thus to raise the standard of surgery and to confer the two degrees has been welcomed on all hands. This, however, is only one of the alterations. The number of examiners has been increased both in medicine and in surgery and two new appointments have been made to allow a separate examination in pathology, while hygiene has been transferred from the examiners in medicine to those in forensic medicine, who are now styled examiners in "forensic medicine and hygiene." The examination, under the altered conditions, was visited and inspected for the General Medical Council in the past winter and the highly satisfactory result was reported to the Council at its last session.[1] The general scope of the different examinations is well illustrated by the papers which were appended to the report of the inspector and the number of marks allotted to each subject was also there given, the candidate having to obtain half marks to be permitted to pass, while the principle upon which honours were awarded lying outside the scope of the Council was not described.

An invariable recommendation of the General Medical Council that "a candidate should not be orally examined, except in the presence of two examiners" appears to have been disregarded, the *vivâ voce* examination being invariably conducted by a single examiner who himself fixed the marks awarded to the candidate. This course of action is condoned, even justified, by the inspector of the Council, by the difficulty and expense which would be otherwise involved when the number of candidates is large; and it is explained by the Academic Registrar that in the subject of medicine alone the work of every candidate was estimated independently by each of the four examiners, and this so thoroughly that it seemed to provide all the checks necessary against the unfair operation of the personal equation in the individual examiner. The knowledge of this will probably prove consolatory to those candidates, if there are any, who leave any part of the examination with a feeling of sorrow or resentment, but we are bound to regard any divergence from the scheme of inspection of which the General Medical Council has approved with some concern. However venial in a special case a relaxation may be, it still remains a good general rule that more than one examiner should conduct a *vivâ voce* test simultaneously. The report of the Examination Committee of the Council draws the attention of the Council to this departure from the usual recommendations, but arrives, nevertheless, at the conclusion that the final examination of the University of London in medicine, surgery, and midwifery is "sufficient," and more than sufficient, within the meaning of the Medical Acts. Such a conclusion must be very satisfactory to all who have had any share in arranging the details of the examination, and it is evident that the authorities are actuated by an ardent desire to make every part of the examination as complete and as practical as possible. The percentage of rejections appears to have been somewhat less than usual, which goes to prove that the new conditions are better adapted to the general teaching of the student.

The Diagnosis of Glanders.

AN able report by Dr. W. B. WHERRY, bacteriologist in the Government laboratories at Manila, has been presented, under the title "Glanders, its Diagnosis and Prevention," to the United States Department of the Interior and published as Report No. 24 of the Bureau of Government Laboratories, Manila, November, 1904. It is of particular interest to English medical readers at this moment when the increase of glanders among us is being made the subject of discussion. The report gives a short account of the general nature and distribution of the disease, including a description of two cases observed in man in the Philippine Islands. Glanders is now somewhat prevalent in Manila, since during the year between Sept. 1st, 1903, and August 31st, 1904, of 3764 horses imported 165 were condemned for glanders, killed, and cremated. Dr. WHERRY'S personal experience, therefore, of a most dangerous plague has been unusally large and his report forms a valuable *résumé* of the chief facts known about the disease. There is nothing particularly novel about his teaching but his words serve to recall to our memory the characteristics of a malady with which but few medical men are familiar.

The organism, the bacillus or bacterium mallei, occurs, of course, in the discharge from the nostrils, in the pus from the specific ulcers, in the more recent nodules in the internal organs, and occasionally in the blood in acute glanders. Although the organism has very feeble powers of resistance outside the body the disease is very infectious and is transmitted by contact, by inhalation, by food and drink, and by infected harness or clothing coming in contact with abrasions of the skin. There are four types of the disease according to Dr. WHERRY'S classification—namely, acute and chronic glanders, in both of which the mucous membrane of the nares, together with the adjacent lymphatic glands and the lungs, are affected and acute and chronic farcy where the process is limited to the skin and its lymphatics. Acute glanders is the common type of the disease in man and in the mule and ass, though less common in the horse. The incubation period, here, is from three to five days, when inflammatory symptoms appear at the site of infection and there are general febrile disturbance and malaise. A day or two later the mucous membrane of both nares becomes hyperæmic and may show punctiform hæmorrhages and later small pustular nodules. There is a copious discharge from the nostrils, at first thin and watery, but later muco-purulent and even streaked with blood. In the horse the submaxillary glands become enlarged on the affected side, nodules form in the lungs, and death occurs in one or two weeks. In man there is often intense pain in the joints and muscles, and abscesses may form in them. An eruption of papules developing into pustules appears on the skin, especially on the face and over joints. These may simulate small-pox pustules and be regarded as such, as occurred in one of the cases recorded by Dr. WHERRY in his report. This form of the disease is invariably fatal, usually within eight or ten days. In chronic glanders, which is rare in man but not infrequent in the horse, the onset is insidious and the course is indefinite. In the horse there is a sticky, muco-purulent secretion from the nose associated with the deposit of greyish nodules on the nasal septum which subsequently break down to form ulcers. Similar ulceration may occur in the frontal sinuses, Eustachian tubes, and larynx, and the lungs frequently present numerous nodules. In these cases, both in man and horses, diagnosis may be only possible by bacteriological tests. In farcy the disease is usually inoculated through the skin, nodules are formed in the skin and subcutaneous tissues and these may develop into abscesses which discharge externally. The neighbouring lymphatic vessels are inflamed and swollen and along their course secondary subcutaneous nodules appear, forming the so-called farcy buds. The neighbouring lymphatic glands become involved and embolic foci may form in the spleen and other viscera. Acute farcy is usually fatal in from 12 to 15 days, while the chronic form may last for months or even years.

The diagnosis can be established by the use of mallein as we pointed out in a leading article last week on the subject This test is of the greatest value in determining the presence of infection in doubtful cases or in "contacts." In healthy horses the injection produces no effect on the temperature or general condition, although a local reaction develops of much less extent than in glanders and lasts about 24 hours. All possible care should be taken in the diagnosis of suspicious cases, as the manifestations are not always typical and it is not uncommon for a case to go unrecognised. The two cases in human subjects reported by Dr. WHERRY illustrate in a marked degree the difficulties of diagnosis which were experienced in the case recently received into St. George's Hospital. Here it may be remembered the case was originally believed to be one of pneumonia. One of Dr. WHERRY'S cases was only suspected after death, when seen by a member of the Harvard Commission on Glanders, to be a case of glanders; it had been previously regarded as one of pyæmia or of acute rheumatism or possibly small-pox; while in the second case the diagnosis was not established until just before death. The prevention of the spread of the disease can only be effected by the systematic stamping out of foci of the disease as they occur, and by the disinfection of infected yards, stables, harness, and utensils.

Wood *v.* Bailey.

THE case of WOOD *v.* BAILEY, heard on June 7th at the Isle of Wight county court, before his honour Judge PERCY GYE, furnishes a curious illustration of the perverted view sometimes taken by the public with regard to pecuniary responsibilities to medical practitioners. The plaintiff, Dr. G. BENINGTON WOOD of Shanklin, sued the defendant, Mr. JOHN BAILEY, a draper of the same place, for £13 10s.

for medical attendance upon his son. With regard to the facts there appeared to be no dispute. The defendant's son returned home convalescent from pleurisy and soon after his return suffered from a fresh attack of the same malady. The plaintiff was called to him in February, 1903, attended him until the 10th of the following April, and had at least one consultation about the case with Dr. T. A. ROSS of the Royal National Hospital for Consumption at Ventnor, who approved of what was being done. On April 10th the defendant wrote to inform the plaintiff that he had decided to put the case into other hands and to have an "unfettered opinion," which he does not seem to have obtained until two days later when Dr. J. COWPER and Dr. J. A. B. HAMMOND were called in and took charge of the case. They performed paracentesis and the patient eventually made a good recovery. The plaintiff, in acknowledging the defendant's letter of dismissal, wrote that he relinquished the case with a clear conscience; and in due course he sent in a claim for his professional charges, which were nevertheless suffered to remain unpaid. When applied to for a settlement in April of the present year, and therefore two years after the termination of the attendance, the defendant not only denied his liability but said that he had been put to an expense of £200 by the plaintiff's "wrong treatment" and that he ought to have compensation instead of being called upon for payment. There was absolutely no defence. Dr. J. WARD COUSINS, Dr. ROSS, and Dr. TURNER all testified to the propriety of the plaintiff's treatment of the case; and Dr. COWPER, who superseded him, declined to criticise this treatment in the witness-box. His honour, of course, gave judgment for the amount claimed, with costs, mentioning the total absence of any evidence that the plaintiff had failed to do what was necessary and adding that it was important for the public to understand that they could not resist the payment of medical fees because the patient died or was not cured. He might have added that there was still less ground for such resistance in the fact that he was not cured within some specified time; and this, so far as we can gather from the report, was all that could be urged on behalf of the defendant.

It is sometimes not uninteresting to try to look dispassionately at the conceivable grounds of an erroneous view. Every practitioner is aware that his charges will occasionally be disputed by people who know them to be perfectly just and reasonable but who do not like to pay them and who trade on the frequent unwillingness of members of the profession to insist upon their rights. This unwillingness has its most usual foundation in the knowledge that illness is more or less a misfortune, and in a feeling resembling that of CHAUCER'S Persoun, who was "ful loth to curse for his tythes." It is strengthened by the press of daily occupations, by the "glorious uncertainty" of the law, by the possibility that a verdict may, after all, be unproductive, and sometimes, perhaps, by a consciousness that strict insistence upon the most undoubted rights may be impolitic. On all these considerations dishonest debtors trade; but we will assume that the defendant in WOOD v. BAILEY was not influenced by them and that he was an honest man who, by some mental twist difficult of comprehension, had really persuaded himself that a medical practitioner ought not to be paid unless the friends of the patient were satisfied with his conduct of the case. He evidently recognised his perfect right to dismiss his son's medical attendant and to employ another, for he acted upon this right, if not as soon as he felt dissatisfaction at all events as soon as the feeling became sufficiently acute. The difficulty is to conceive the course of reasoning, if so it may be called, which led him to believe that his dissatisfaction, which does not appear to have been based upon any suggestion of neglect, could exonerate him from pecuniary liability for the attendance that he had already sanctioned. A medical man is bound, of course, to bring reasonable knowledge and skill to the service of his patient and a manifest failure to do this would necessarily vitiate his claim. Mr. BAILEY does not appear to have had any ground of this description. The plaintiff had called in consultation a well-known physician of the locality, whose fee was presumably paid by the defendant, and who concurred in the propriety of the treatment that was being pursued. It is true that Dr. COWPER and Dr. HAMMOND are said to have performed paracentesis and to have given exit to a collection of pus, but it was also in evidence that Dr. WOOD had previously tested the character of the fluid in the pleural cavity with the aid of an exploring needle, had found it to be serous, and had arrived at the conclusion that paracentesis was not then indicated. That it was indicated and performed on a subsequent occasion is a fact entirely irrelevant to the issue raised at the trial. Even if the question of performing it at any given time had been one as to which Dr. WOOD differed from those who succeeded him he would manifestly have been bound to act upon his own opinion and not upon theirs, even supposing that he had been made acquainted with it. Under whatever aspect we look at the defence we can attribute it to nothing else than sheer wrongheadedness.

We are entitled to suppose that Dr. COWPER, who was called for the defence and who declined to criticise the plaintiff's treatment, was an unwilling witness; and hence we must exonerate him from all responsibility for the defendant's resistance to a just claim. It would, nevertheless, be satisfactory to the profession to hear from him that he had endeavoured to prevent a defence which he must have foreseen to be futile and that he had striven to enlighten Mr. BAILEY with regard to the true nature of his position and his responsibilities. A medical man who supersedes another during the actual progress of an acute illness is placed in an extremely critical and responsible situation, and is bound, so far as may be possible, to guard the reputation of his predecessor. He is not bound to agree with him, in diagnosis, in prognosis, or in treatment; but, more especially if his opinion should appear to be justified by results, he is bound to point out the extent to which, in the given circumstances, a different view might have been entirely legitimate. The public are prone to suppose, when the erroneous character of any medical opinion or medical treatment has been shown by time, that the error must have been obvious from the first to any properly instructed person; but, if this were so, the art of medicine would be much easier than it is. No one but a practitioner can appreciate the anxieties that frequently arise from the obscurity of the conditions with which he is called upon to deal, or the watchfulness necessary to be observed in order to miss none of the indications, veritable straws it may be, but showing the direction of the wind, by which the obscurity may at some given moment be lightened or removed. Reading between the lines of the report it seems highly probable that the defendant in WOOD *v.* BAILEY would try to justify himself to his own conscience by saying, "Dr. WOOD did not perform paracentesis and my son was very ill; Dr. COWPER did perform it and he recovered; therefore Dr. WOOD ought to have done it at an earlier period." Such a course of reflection might not be unnatural in an ignorant person, but it is none the less absolutely unsound; and, as regards the pecuniary liability, the phraseology of the judge leaves nothing to be desired in the way of explicitness. A person who employs a medical man is responsible for paying his proper and customary charges and cannot escape from this liability by pleading any amount of personal dissatisfaction with his conduct of the case. Absolute neglect or malpractice established by skilled evidence would place the question upon a different footing, but neither of these was even alleged as against Dr. WOOD. The profession generally are much indebted to him for his determination to insist upon receiving his proper dues; and the Medical Defence Union, by which the case of the plaintiff was conducted, has given one more proof of its signal usefulness to those for whose protection it was called into existence.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND: ELECTION OF MEMBERS OF COUNCIL.

FOR the four vacant seats on the Council of the Royal College of Surgeons of England six candidates have been nominated. Two of them, Mr. Edmund Owen and Mr. Rickman J. Godlee, have already served a term on the Council and now offer themselves for re-election. There can be no question as to the propriety of reappointing them. They have both proved useful members of the Council and from their work and their position in the profession they thoroughly deserve a renewal of the confidence of the Fellows, but their election must not be taken for granted because of the unfortunate proclivity that the Fellows have for plumping. We cannot but look upon plumping as a shirking of responsibility and deplore that so many Fellows should be willing to waste their votes. If Mr. Owen and Mr. Godlee are re-elected there will remain two other vacancies, and for these, in order of seniority, the following candidates are presenting themselves: Mr. Andrew Clark of the Middlesex Hospital, Mr. C. H. Golding-Bird of Guy's Hospital, Mr. Harrison Cripps of St. Bartholomew's Hospital, and Mr. W. Bruce Clarke, also of St. Bartholomew's Hospital. Inasmuch as one of the two vacancies on the Council has been occasioned by the retirement of Sir Henry G. Howse it would be only right that Mr. Golding-Bird should be elected in his place. Guy's Hospital is a very important medical school and at present it has only one representative on the Council, Mr. R. Clement Lucas. Mr. Golding-Bird is one of the full surgeons of that institution and occupies a deservedly high place in British surgery. At a previous election he almost secured a seat. Between the three remaining candidates it is somewhat difficult to make a choice. Mr. Andrew Clark is surgeon to the Middlesex Hospital which already has two strong representatives on the Council, Mr. Henry Morris and Mr. A. Pearce Gould. A very similar difficulty confronts us when we consider the claims of Mr. Harrison Cripps and Mr. Bruce Clarke. They are both members of the staff of St. Bartholomew's Hospital and that hospital already has four representatives on the Council. With a full appreciation of the part that the school of St. Bartholomew's plays in the medical world we must confess that we think four representatives are sufficient, but we think also that two representatives are sufficient for the Middlesex Hospital. We must, however, suggest the addition of a representative either to one or the other. A consideration of the relative professional claims of the candidates does little or nothing to diminish our embarrassment, for they all hold a high place in contemporary surgery and have contributed to the literature of the science. We acknowledge that the claims are well balanced, but only one of the three has hitherto manifested any special interest in College politics. Mr. Bruce Clarke had much to do with the Association of Fellows a few years ago and for a time he was secretary and this fact gives him an additional claim on the suffrages of those Fellows who are interested in the well-being and the progress of the College. We venture therefore to think that the vacant seats would be best occupied by Mr. Edmund Owen, Mr. Rickman Godlee, Mr. Golding-Bird, and Mr. Bruce Clarke.

"THE ACCURSED KNIFE."

"THE phrase," writes an Italian correspondent, "is Antonio Gallenga's, who lost no opportunity of impressing on his compatriots the urgency of a radical reform in their penal code if they were not to maintain that 'sinister priority' in homicide which has made them a by-word among the nations. Amid the universal horror at the assassination of the Hellenic Premier there was one note of consolation in Italy that 'the assassin this time was not an Italian'—though his victim's rank, his methods, and the instrument he employed seemed to favour the presumption that he must have hailed from the 'classic land of homicide,' or, at least, have qualified in the school of Caserio, of Luccheni, and of Bresci, the assassins of President Carnot, the Empress of Austria, and King Umberto. The Italian press, in the day now passing, is once more in 'full debate' on the gruesome topic of the 'Codice Penale e le Coltellate' (the Penal Code and Stabbing Cases), welcoming every aid to its discussion, even from outsiders, and giving particular attention to the article in the *Rassegna Nazionale* by Sir Willoughby Francis Wade, sometime a leading consultant in the Midlands and President of the British Medical Association. Sir Willoughby Wade, in his Tuscan *villeggiatura*, has for some years been studying the topic and in a previous article in the same periodical threw out, with practical English sense and the impartiality born of 'detachment,' a series of suggestions embodied in the Bill for penal reform promised last spring by his Excellency Signor Ronchetti, Minister of Grace and Justice, in concert with the Prime Minister and the Minister of the Interior. That artic dealt mainly with the lethal weapon employed and wo ld up with practical indications as to the form of knife ich might be exclusively permitted for sale under Gove ment sanction and be legitimately carried by its owr. Th article now under notice takes cognisance of th enalties attaching to the wounds inflicted and concludes n ano er series of suggestions not less practical, as the omoters o the Bill will doubtless find in its committe age. The are too elaborate and too detailed for env ration or cussion here but their acceptance or a ication wil effective and salutary only in the degree in which certain ethnographic and historical conditions are realised and allowed for by the Legislature. 'Italians,' says Sir Willoughby Wade, 'are of an impressionable and ardent temperament, qualities which are not without their redeeming side. But *corruptio optimi pessima*, and all of us have the defects of our qualities. It is due, in part at least, to this temperament that "vendetta" is so deeply rooted in Italy'—a 'vendetta' of a kind for which the knife is peculiarly adapted. Baron Garofalo, professor of criminal statistics in the University of Naples, attributes the prevalence of vendetta to an ineradicable distrust of the impartiality of the law—a distrust all too closely connected with the miserable remuneration allowed by the State to the heads of tribunals—and to the consequent suspicion of venality and the temptation to 'take the law into one's own hand.' The same authority, in a memorable paper, illustrated the helplessness of 'education' to antagonise this 'vendetta'—in which he has the support of Sir Willoughby Wade, who points out that education in Italy, though leaving much to be desired, has, on the whole, reduced the numbers of the *analfabeti* (absolutely unlettered), while stabbing cases, fatal or non-fatal, are officially declared to be on the increase. The abolition of capital punishment, universal throughout Italy for 30 years, is now being reluctantly admitted to have coincided with an augmentation of *fatti di sangue* (cutting and wounding with fatal result) and it is even recommended in certain quarters that, as an initial remedy at least, flogging, which stamped out the garrotter in the British Isles, might be tried in Italy towards minimising such *fatti*. The whole subject bristles with difficulties, insomuch that a commission to consider it and devise measures *ad hoc* seems to be the first step indicated for the remedy of a state of things which is becoming, in the words of an Italian, a 'European scandal.' Such a commission should be composed of experts in which medicine as well as law and practical legislation should be represented, dealing as it must with details in which the expert in anatomy, surgery, psychology, criminal psychiatry, jurisprudence, criminology, and even the steel industry, can alone be heard with advantage. Signor Ronchetti, honourably associated with the reform of the penal code, might earn further distinction by organising such a commission, 'which,' concludes Sir Willoughby Wade, 'I have great confidence will one day be set on foot.' *Quod felix faustumque sit.*"

THE DEVELOPMENT AND SUSPENSION OF THE JAWS.

IN an interesting paper communicated to the Transactions of the Odontological Society (Vol. XXXVII., No. 5) Mr. J. T. Carter gives the results of his investigations into the development and suspension of the jaws. Mr. Carter's research has been mainly in connexion with fish and reptiles and shows much careful and thoughtful work. At the commencement of his paper he points out that all anatomical investigation to be of value must be based on the evidence of comparative anatomy. Adult skulls of members of each family must be examined and compared but unless this method is associated with an embryological examination of certain species the investigator is liable to be misled by analogies due to convergence of types. Also he should never consider that similarity of gross structure implies community of origin until the embryology of the creatures under consideration has been carefully worked out. With the assistance of a large number of slides and specimens it is shown that the first elements of a skull to appear are a pair of curved flat rods—the parachordals—which abut on each side of the anterior end of the notochord. Anteriorly to the parachordals another pair of cartilaginous rods appear—the trabeculæ cranii. The parachordals and the trabeculæ eventually fuse with the anterior end of the notochord to form a floor for the support of the brain. Three pairs of sense capsules—olfactory, optic, and auditory—next appear and as the sides of the basilar plate grow upwards to invest the brain these capsules enter into intimate relation with the primitive brain case. In addition to the above structures a number of cartilaginous rods, formed in the walls of the pharynx between the gill slits, must also be considered as part of the skull. The anterior pairs of these rods, though primarily connected with the respiratory function, become modified to assist in the prehension and comminution of food and so form jaws. In the selachians all these elements are practically distinct but ascending the vertebrate scale it is found that they enter into closer relation with each other until in the higher animals all are intimately blended. In the elasmobranch fishes the skull consists only of cartilage the perichondrium of which may be hardened by superficial ossification taking place therein. In recent forms there are no true bones. True bones first make their appearance in the cartilaginous ganoids where is seen superficial ossification on, or just beneath, the surface. In sturgeons, polypterus, and so on, these bones do not enter into close relation with the cartilaginous skull. Dermoid ossification appears to affect the underlying tissues and to stimulate a corresponding ossification in the perichondrium, the differently derived bones more or less fusing together. Dr. Ridewood[1] has recently pointed out that there is no essential difference in the two methods and that dermal ossification, whether due to coalescence of denticles or to hardening about sensory canals, was the primitive form. Even in those cases where the bone is pure cartilage bone the ossification of the cartilage owes its origin phylogenetically to a predisposing dermal ossification which no longer appears in ontogeny. So, in the teleostei, there are both ectosteal and endosteal ossification. In the physostomi the ectostoses are still separable from the chondrocranium with its endostoses, but in the remaining orders the investing bones become very closely united. Mr. Carter then shows that from this point upwards in the phylum, through dipnoi, urodela, anura, reptilia, and mammalia, there is a gradual replacement of the primitive cartilaginous cranium by the secondary osseous cranium and that the same applies to the jaws and branchial arches; that the cessation of branchial respiration led to a reduction of the visceral skeleton and that the disused parts were largely utilised in the elaboration of the organ of hearing. In conclusion stress is laid on the great importance of a thorough application of the lessons gained from the comparative consideration of the morphology of the jaws in the treatment of various abnormal conditions which nowadays the dentist is so often called upon to rectify; for the effect of heredity extending back to remote ancestors (how remote the most ardent evolutionist can scarcely realise) is probably far more potent in the causation of variations than is the influence of factors which have only been at work for a few generations.

THE EMPLOYMENT OF CHILDREN.

UNDER the Employment of Children Act, 1903, the London County Council has drawn up a set of by-laws which have been submitted to the Home Secretary for confirmation as required by the Act. These by-laws, which are intended to safeguard the moral and physical well-being of children, can be obtained from the clerk to the council and they deserve the serious consideration of all who appreciate the important bearing which the matter has upon future generations. Some objections having been raised to them the Home Secretary has issued a notice announcing his decision that a public inquiry shall be held into the proposed regulations and Mr. Chester Jones, a barrister, has been appointed to hold the inquiry at the County Hall, Spring Gardens, London, S.W., on Monday next, June 26th, at 11 A.M. On the whole the by-laws seem to us wise and temperate, though there is perhaps some ground of objection to the first, which states that a child under the age of 11 years shall not be the subject of any employment. This may mean some hardship to the very poor, but although the tiny runners of errands may not be asked to do anything beyond their powers children ought not to be looked upon as bread-winners. The by-laws relating to street employment by persons under the age of 16 years should go a long way towards bettering the condition of kerb-merchants and of preventing these young people from being exposed to many of those evils which street trading necessarily implies.

RED RUBBER.

IN a letter published in THE LANCET of June 10th, p. 1610, Mr. F. A. Pond drew attention to the fact that sulphide of antimony is an important constituent of red rubber and he produced certain evidence which in his opinion lent colour to the view that there was possibly a connexion between the use of red rubber rings in the stoppers of mineral water bottles and appendicitis and other intestinal disorders. It is not the first time that an indictment against red rubber has been made and the fact that it contained sulphide of antimony was discussed at a meeting of the Royal Medical and Chirurgical Society in 1876[1] in connexion with tracheotomy-tubes. As far back as 1879 some correspondence appeared in the pages of THE LANCET[2] "On Effervescing Drinks and their Effects," in which one writer asserted that acetate of lead was used in the preparation of indiarubber bands for mineral-water bottles and he was of the opinion that some children had been unwell from drinking lemonade from these bottles. In a letter by another writer the use of acetate of lead was denied and in an editorial note to this letter it was stated that "we, too, have made several analyses of them—i.e., vulcanised rubber bands—and in no case have we found even a trace of lead to be present." The vulcanisation of rubber with sulphide of antimony is carried out on a large scale, and every piece of red rubber which we have examined—including rubber bands, washers, tubing, and rings—proved to contain this substance. According to our analysis the average amount was 16·83 per cent. of penta-sulphide of antimony, which is equivalent to about 10 per cent. of metallic antimony and 1·94 per cent. of sulphur in addition to that combined with the antimony. We could find no zinc nor could a trace of arsenic be detected in the sulphide. As to the possibility of mineral waters exerting any appreciable solvent action on the sulphide of antimony we think this is improbable as, excepting by the aid of hot strong acids or strong alkali, sulphide of antimony is with difficulty soluble. However, in order to clear up this point a number of experiments were made in which soda-water (containing sodium bicarbonate), potash water (containing potassium bicarbonate), lemonade (containing citric acid or tartaric acid and sugar), and beer were left in contact with rubber rings containing 16·83 per cent. of penta-sulphide of antimony. The test was somewhat severe as the liquids were shaken vigorously and frequently in contact with a large surface of red rubber and they were left for four days. On testing the liquid for antimony not a trace could be found. Nor was any soluble antimony found in a number of specimens of mineral waters contained in bottles provided with red rubber rings. In some instances, however, small specks of rubber were found in the liquid and the rings showed decided signs of wearing away. This effect of constantly turning the stopper on the rubber ring would, of course, be the same on other materials free from antimony, as, for example, grey rubber, cork, wood, and so on. The question remains whether if these pieces of detached antimonial rubber were swallowed they would set up an irritating action in the direction indicated. Chemically speaking, it is difficult to dissolve the sulphide of antimony out of red rubber. Prolonged treatment in hot strong alkali or acid will, of course, effect solution and will take out some sulphur, but physiological reagents are neither hot nor concentrated. And even if the red rubber were disintegrated the amount of antimony would be small, since it does not exceed, according to our analysis, 10 per cent. of the metal and the wearing away of the ring in the aerated water bottle is spread over a long time. Still, the use of a mineral compound containing an undoubtedly poisonous metal is always undesirable, even in small quantities, when articles of food and drink are concerned and the conviction that no harm is likely to ensue in such cases can only be carried home by doing away altogether with the suspicious component.

THE "FAKING" OF HIGH TEMPERATURES.

OF the value of the thermometer in clinical medicine there can be no question. Before the utilisation of the thermometer in practice some idea could be formed of the temperature of the patient by palpation but to be able to estimate exactly the degree of increase of temperature was an enormous step and, moreover, in some conditions, as in the cold stage of malaria, the sensation communicated to the hand of the physician is a very fallacious guide to the temperature of the patient. The great trust, however, which is placed in the indications of the clinical thermometer is not always justified, for patients have found that it is by no means difficult in one way or another to induce a thermometer to indicate a far higher temperature than that of the body. The motives for these deceits are various. Sometimes it is to obtain treatment as an in-patient of a hospital; sometimes it is merely to excite notice or sympathy, while in other cases the sole motive is to contribute to the amusement of the patient himself. The excitement caused in a ward by the occurrence of a temperature of 106° F. or even higher is not likely to be forgotten by any patient present at the time, and many patients will wish to emulate this achievement. The means by which a thermometer is induced to indicate a pyrexial temperature are numerous. The simplest is the utilisation of hot food. A cup of tea will send the mercury upwards in a rapid and surprising manner, and even hot potatoes or pudding will be equally efficacious. A poultice, too, or a fomentation will serve the purpose, and a hot water bottle has also been requisitioned. This is the easiest method and will suggest itself to the veriest tyro. The next mode that may be mentioned utilises the effects of friction. If a clinical thermometer be grasped firmly near its lower end and the bulb rubbed smartly on any texture—flannel is the most suitable material—the mercury will soon rise and, indeed, the bulb may become too hot to be pleasant. This method puts a good deal of strain on the constriction just above the bulb and the thermometer is likely to give way there. In some instruments the mercury can be thrown up the scale by an energetic jerk but this should never deceive an observant physician, for there will be a very obvious break between the constriction and the lower part of the mercurial column. The desire for thermometers which act rapidly has necessitated the production of instruments the bulbs of which have very thin walls. In these thermometers it is possible by pressure very carefully adjusted to compress the bulb to a minute extent, causing a small portion of the mercury to leave the bulb and to pass into the tube, so that a high temperature is indicated. Malingerers exert this pressure chiefly by means of the teeth and therefore this method works best when the temperature is taken in the mouth. The pressure required is not great when the thermometer is suitable. In some very thin subjects it seems possible that even an axillary temperature can by pressure be made to appear unduly high. These are the methods by which pyrexial temperatures can be "faked" and it is necessary for the physician to be on his guard against them. We do not venture to say that all the cases of very high temperatures, such as 115°, 120°, 125°, and even higher, that have been recorded are fraudulent, but we have no hesitation in declaring that in the vast majority of cases there has been fraud. It is often exceedingly difficult to detect, but it is always possible, if sufficient care be taken, to demonstrate that the thermometric readings are untrustworthy. The most important point is to have several thermometers; one in each axilla, one in the mouth, and one in the rectum. If these all give widely divergent readings it is clear that fraud is being employed. In many conditions, such as hemiplegia, there may be a well marked difference between the temperatures taken in the two axillæ, and this has to be borne in mind, but a marked divergence between the results will infallibly point to deceit. The rectal temperature is by far the most trustworthy, but for absolute certainty the thermometer must be held in position the whole of the time. Should it occur to any of our readers to experiment in the direction of "faking" high temperatures we would suggest the desirability of laying in a good supply of thermometers, for some are sure to be broken. The pressure method is especially fatal.

ACUTE OBSTRUCTION OF THE DUODENUM IN POTT'S DISEASE OF THE LUMBAR SPINE.

IN the *Archives Générales de Médecine* of March 14th Dr. Gaussel has published a case in which Pott's disease of the lumbar spine led to the formation of an abscess behind the duodenum and acute obstruction of that organ—a complication which does not seem to have been recorded previously. A man, aged 46 years, was admitted into hospital under the care of Professor Grasset in August, 1903. Since 1890 the patient had suffered from attacks of bronchitis accompanied by hæmoptysis. In front on the left side the chest was hyperresonant, expiration was prolonged, and there were numerous sibilant râles; on the right side at the apex there were dulness and subcrepitant râles. Behind auscultation gave the same signs. The cardiac dulness was absent and the heart sounds were masked. There was no pyrexia. Chronic bronchitis, emphysema, and tuberculous softening of the right apex were diagnosed. The sputum contained tubercle bacilli. The patient quickly improved and was able to get about and make himself useful in hospital. But in October he complained of pain in the lumbar region which impeded walking and caused him to curve his body to the right. The pain radiated into the left flank and was increased by pressure on the spine at the level of the fourth lumbar vertebra. There was no projection of the spine and radioscopy was negative. The pain persisted in spite of local applications and was not relieved by rest in bed. Indeed, it seemed to the patient to be increased when he lay on his back. At the beginning of December the pains still persisted and there was further weakness of the legs in walking, which was always performed with the trunk curved to the right. On Dec. 4th examination revealed slight atrophy of the left lower limb; Babinski's sign was not present. There was paresis of the flexors of the thighs on the pelvis, for the patient could not raise himself to the sitting posture without the aid of his arms. The presence of this paresis and of the pain at the level of the fourth lumbar vertebra pointed to pressure within the spinal canal on the cauda equina. Tuberculous meningitis at this spot was thought of, for the negative result of radioscopy seemed to exclude caries. Under rest in bed improvement took place and the patient was able to leave hospital in April, 1904. The paresis had not progressed and he could walk better. On June 16th he was readmitted suffering from profuse hæmoptysis and dyspnœa. The hæmoptysis seemed to come from the right apex where there were signs of great congestion. On the left side there was generalised bronchitis which tended to invade the small bronchi. The evening temperature was 101·3° F. On the 20th he complained of acute abdominal pain and vomited a large quantity of greenish liquid containing much bile. The pain was situated in the right hypochondrium and was spontaneous but increased by attempts at palpation. There was also hiccough. The vomiting was continuous; all liquids taken were rejected mixed with bile after a short sojourn in the stomach and injections of morphine and heroin pills had no effect. Duodenal obstruction below the ampulla of Vater was suggested. On the 23rd the vomiting persisted, the pain was always acute, and incessant hiccough exhausted the patient, who lay helpless in his bed. Only nutrient enemata and injections of morphine were given. On the 24th the vomiting had ceased but the pain was always acute and the hiccough continued. On the 26th milk could be taken by the mouth but the hiccough persisted. The patient became weaker and died from the thoracic disease on July 1st. It was thought that the duodenal obstruction was due to tuberculous peritonitis localised in the neighbourhood of the duodenum. The necropsy showed great congestion of the lungs. At the right apex was tuberculous softening; the lung was full of small tubercles surrounded by fibrous tissue. There were no signs of peritonitis, but behind the duodenum, in connexion with the fourth lumbar vertebra, was a chronic abscess of the size of a large walnut. The spinal membranes were normal. The abscess contained tuberculous pus and communicated with a cavity in the fourth lumbar vertebra. A probe was passed into the latter and on slight pressure it perforated the thin barrier of fibrous tissue which separated the abscess from the spinal canal. Although the meninges and nerves at this spot appeared normal microscopical examination showed the existence of neuritis. Dr. Gaussel thinks that the duodenal obstruction was due to spasm provoked by the abscess.

THE PIETERMARITZBURG LABORATORY.

THE annual report of the Government bacteriologist and director of the Pietermaritzburg Laboratory for the year ending in December, 1903, serves to show that in matters affecting the public health at least we can not only "think imperially" but can convert our ideas into labours for the good of the empire. The establishment of such laboratories as this at Pietermaritzburg is primarily intended for the benefit of the colonies in which they are situated, but the work done in them has a far greater area of usefulness. The director, Mr. H. Watkins-Pitchford, reports the growing use made of the laboratory by the health and veterinary departments, the private practitioner, and by the criminal investigation departments. The routine work consists in examinations for the diagnosis of enteric fever, diphtheria, malaria, &c., the analysis of water-supplies, and the preparation and supply of some half-dozen varieties of vaccine. Of the vaccine for quarter evil alone some 17,000 doses were distributed during the year. In addition to the routine work a very valuable bacteriological investigation of plague in Natal in 1902-03 was undertaken. The morphology and vitality of the bacillus pestis as met with in this epidemic were carefully studied. The report is lavishly illustrated with reproductions of excellent photographs and forms a very complete account of the variations in morphology produced by alterations in the composition of the media employed and changes in other cultural conditions. A valuable series of experiments was undertaken to control the important results obtained by Professor W. J. Simpson at Hong-Kong, which showed the possibility of the infection of many varieties of domestic animals by the ingestion of infectious food. The results obtained in Natal were very different from those obtained in Hong-Kong and agree with the earlier observations of French investigators. It was found practically impossible to infect South African herbivora, pigs, and birds. The director is to be congratulated on the issue of this excellent report.

THE THAMES STEAMBOATS.

THE London County Council has done many things; for some of which it has been heartily praised and for others equally heartily condemned. Its latest venture, however, can, we imagine, meet with few detractors. Anything which encourages Londoners to know their own river well deserves warm approbation and anything which serves to relieve their over-congested roads perhaps even warmer praise. A steamboat service which is likely to meet both these ends to a large extent is therefore an achievement on which the Council may be cordially congratulated. It is a truism that those who inhabit fine towns rarely know the fine sights of their own city so well as the occasional visitor does. They do not set about seeing these things, knowing that they are always at hand. Thus it happens that there are thousands of Londoners who have never realised all that there is which appeals to the eye and to the imagination that can be seen in a trip from Greenwich to Battersea even. Such ignorance should now no longer remain possible. From the hygienic point of view as well as from the artistic there is much to be said for the river-way. And the business man or clerk who is fortunate enough to be able to reach his daily destination by water has a boon that is denied to him who travels in a crowded carriage on the Metropolitan or the Tube railway. The air is fresh on the water even though that water runs through the midst of a mighty city.

RADIUM AND VITALITY: "RADIOBES."

CONSIDERABLE publicity has been given in the lay press this week to the results of a remarkable series of experiments made in the Cavendish laboratory at Cambridge by Mr. John Butler Burke on the spontaneous action of radioactive bodies in gelatin media. The first account of these experiments appeared in a signed letter published in *Nature* of May 25th, and in this account the writer promised more details "shortly," but so far as we know no further communication has been published. Briefly the experiment consisted in placing radium salts in sterilised gelatin culture, care being taken to sterilise both the salt and the broth before commencing the experiment. After 24 hours or so in the case of the bromide and about three or four days in that of the chloride a peculiar culture-like growth appeared on the surface and gradually made its way downwards until after a fortnight in some cases it had grown fully a centimetre beneath the surface. The controls showed no growth whatever. At first sight on microscopical examination the growth appeared to be due to microbes but as they did not give subcultures when inoculated in fresh media they could scarcely be bacteria. Their presence would appear to be due to the spontaneous action of the radium salt upon the culture medium and not solely to the influence of anything which previously existed therein. Mr. Burke concluded after a careful and prolonged examination of their structure, behaviour, and development that they are highly organised bodies, although not bacteria, and that they arose in some way from the action of the invisible particles of radium. He has proposed to give these bodies the name of "radiobes" as indicating their resemblance to microbes as well as their distinct nature and origin. It has been suggested that they are, after all, crystals, but Mr. Burke is confident that they are not of the nature of crystals. Whilst admitting the extreme interest of these results the evidence that gelatin culture has been vitalised by purely physical and inorganic agencies, that life has been established out of inanimate materials, is not at the present stage of the experiment convincing and further results will be awaited before the opponents of the "spontaneous theory" may be induced to abandon their position.

THE MEDICAL OFFICER OF HEALTH OF THE GLOUCESTERSHIRE COMBINED SANITARY DISTRICT.

A CONFERENCE of representatives of the urban and rural districts comprised in the Gloucestershire combined sanitary district, convened at the request of the Local Government Board, was held at Gloucester on June 19th. The object of the meeting was to consider the present position, in view of the recent action of the Chipping Sodbury council, in reference to the appointment of medical officer of health. All the councils in the combined district were represented with the exception of Chipping Sodbury. Motions favouring a continuance of the combination were adopted, reference was made to the length of time of Dr. F. T. Bond's services and to the efficient manner in which he had carried out his duties, and the Chipping Sodbury council was urged to reconsider the matter.

CHILDBED MORTALITY.

IN a paper on the Mortality of Childbed read before the Obstetrical Society of London Dr. Robert Boxall compared the records of the York-road Lying-in Hospital and those of the Registrar-General for London, England and Wales, Scotland, and Ireland.[1] The conclusions at which he arrives are interesting. In spite of the large number of severe cases sent in the death-rate in the hospital is much lower than that recorded in the Registrar-General's returns. Both with regard to the accidents of childbed and septic diseases the hospital death-rate is less than that of private practice. If the mortality of childbirth for the last 25 years in the hospital and that for the last three years for which figures are available in England and Wales are compared the ratio is as 3 to 4. During the last 16 years only four fatal cases of septic disease, all introduced from without, have been treated in the hospital. Dr. Boxall in calculating the death-rate has based it upon the number of registered births and from his statistical studies draws the following conclusions. The total death-rate from childbirth has not diminished in England and Wales, in Scotland, or in Ireland, where it is abnormally high as compared with the other divisions of the kingdom, but in London it has declined considerably. The death-rate from the accidents of childbirth has declined slightly in each division of the kingdom but is abnormally high in Ireland and in London has markedly diminished. The death-rate from puerperal septic diseases has, if anything, shown a tendency to increase in each division of the kingdom but in London has been declining for at least the last decade. It is most interesting and encouraging to note that the total death-rate in these cases is diminishing in London and we may justly draw the conclusion that the stricter training of both students and nurses is at last bearing some fruit. No doubt in Ireland the ignorance of the midwives and the difficulty of obtaining proper medical attendance are both very great and this may well explain the abnormally high death-rate prevalent in that country. We may certainly hope that in another ten years' time, when the influence of the new Midwives Act begins to make itself felt, the death-rate not only in London but all over the kingdom will show signs of a steady decrease. In view of the very high death-rate in childbed which Dr. Boxall has shown to prevail in Ireland it is all the more to be regretted that the new Act does not apply to that country.

---

[1] THE LANCET, May 13th, 1905, p. 1269.

A MEMORIAL TO THE LATE DR. GEORGE VIVIAN POORE.

WE have much pleasure in announcing that it is proposed to place a memorial in University College Hospital to Dr. George Vivian Poore who died in October, 1904. For 30 years he was on the hospital staff as assistant physician and physician and at University College he was for nearly 20 years professor of medical jurisprudence and afterwards professor of medicine. His distinguished services to the hospital and medical school, his personal merits, and the practical value of his literary work justify an appeal to his numerous friends and old pupils to establish a permanent memorial of him. If a sufficient sum is collected a bed in the hospital will be named after him, as was done in the case of his friend, the late Mr. Marcus Beck, and a medallion portrait will be placed in some appropriate position. The necessary arrangements are being made by a large committee, consisting of past and present members of the hospital staff, together with the Right Hon. Lord Reay, President of University College, the Right Hon. Lord Monkswell, vice-president of University College and treasurer of University College Hospital, Sir Richard Farrant, treasurer of University College, Dr. T. Gregory Foster, principal of University College, and Mr. Henry Lucas, chairman of the hospital committee. Dr. Sidney Martin is the secretary to the committee. Subscriptions may be sent to the treasurer, Mr. R. J. Godlee, F.R.C.S. Eng., 19, Wimpole-street, Cavendish-square, London, W.

RECURRING SUBLUXATION OF THE FEMUR AFTER INJURY.

IN the *New York Medical Journal* of June 3rd Dr. P. Le Breton has published an important case in which recurring subluxation of the femur followed an injury which he regards as "incomplete fracture of the neck of the femur" but which probably would be more correctly described as impacted fracture. A girl, aged 15 years, was seen on Nov. 17th, 1903. 14 months before she had fallen on the left hip in the street. Although in considerable pain she was able to walk home. She did not go out for three weeks but limped about the house. After the injury she always walked with the leg and thigh flexed and stepped on the ball of the foot, rotating the leg slightly outward. After the three weeks she began to go to school again. She complained of slight pain which was relieved by adopting the attitude described for walking. Five months later she received a push from another girl which strained the hip and increased the pain. For the last three months she had noticed on attempting to extend the thigh while in the upright position a sudden jerk or slip at the hip which caused sharp pain. On examination she was found to be a well-developed, strong girl. While standing or walking she kept the thigh and leg somewhat flexed and the heel off the ground. There were slight outward rotation of the limb and prominence of the great trochanter. On lying down the limb was easily placed in a normal position but on rising the deformed position was immediately assumed. On attempting forcibly to straighten the thigh in the upright position the trochanter suddenly moved forward and became less prominent. It seemed as if the head of the femur slipped into its socket over the edge of the acetabulum or an abnormal ridge. A fulness could be felt under the gluteal muscles which disappeared as the slipping occurred. The sensation resembled that produced on reducing a congenital dislocation. Voluntary muscular spasm resisted every movement of the thigh but there was no limitation of motion. The left leg was three-eighths of an inch longer than the right, which was probably due to overgrowth. Slipping of the bone did not occur in the prone position. A skiagraph showed thickening of the neck of the femur and diminution of its angle but not enough to give rise to the symptoms of coxa vara. As the parts were in a normal position when the patient was recumbent a modification of Lorenz's treatment was advised. A plaster-of-Paris bandage was applied in this position to fix the leg in place until the tendency to subluxation was overcome. To prevent the patient from assuming her old position it was found necessary to extend the plaster from the lower ribs to the ankle. She walked well without pain and brought the sole to the ground for the first time in over a year. After three months the plaster was removed and she walked normally except for a limp which later disappeared. There was no tendency to subluxation and the slipping movement could not be reproduced. All the movements of the hip were normal but the knee was stiff from its confinement. Some months later recovery was complete. Dr. Le Breton thinks that the accident caused an incomplete fracture of the neck of the femur which nature repaired and that to favour repair the girl adopted a position which resulted in stretching of the capsule of the hip-joint and finally in subluxation, so that on standing the head of the femur was not in the acetabulum. But it seems more probable that the injury involved the capsule as well as the neck of the bone and that some tear in the former was the cause of the subluxation.

VOYAGES D'ÉTUDES AUX EAUX MINÉRALES.

THE annual "voyage" of medical men and students will this year comprise the most important stations in the Western Pyrenees. It will start from Luchon on Friday, Sept. 1st, and will terminate at Arcachon on Thursday, Sept. 14th. The price to be paid, which includes everything between these two places, is £12. There are no extras of any kind. The travelling is by first-class special train and the accommodation is the best which each place has to offer. In order to reach Luchon a ticket (first- or second-class) at half-price will be issued from any selected point on French territory and a similar reduction will be made on the ticket from Arcachon to the point of departure from French territory. The district to be visited is remarkable for its extreme beauty and interest as are the stations for their therapeutic value. Among them are such well-known resorts as Luchon, Cauterets, Saint-Sauveur, Eaux Bonnes, Pau, Biarritz, Dax and Arcachon, together with many of minor importance. The particular features of each place are briefly described by Dr. Landouzy, professor of clinical medicine at the University of Paris. Medical men (who may be accompanied by their wives), medical women, and students in medicine are eligible to take part in the trip. Names must be sent in so as to reach Paris on or before August 15th. They should be accompanied by the subscription (£12) which may be in the form of an ordinary English cheque payable to Dr. Carron de la Carrière, 2, Rue Lincoln, Paris, or to Dr. Leonard Williams, 8, York-street, Portman-square, London, W., from either of whom any further particulars may be obtained. Dr. Boyd B. Joll writes to us to say that Luchon may be reached *viâ* Bordeaux by the General Steam Navigation Company's boat which will leave London on Saturday, August 26th, and which will return to London on Sept. 19th, but those wishing to proceed to Luchon *viâ* Paris will be able to cut the trip shorter by about five days.

THE FRENCH HOSPITAL.

OUR London contemporary, *La Chronique*, gives an excellent account of the French Hospital in London and the convalescent home at Brighton. The former is still further to be enlarged, as the committee, through the energy of M. Pondepeyre, the secretary, has been fortunate in acquiring the freehold property adjoining, so that when the new addition is completed it will occupy the whole block situated between the present site and the junction of Shaftesbury-avenue with Great St. Andrew-street. A large addition has been made to the convalescent home which is now completed and is to be opened by the French Ambassador. The annual banquet was held two weeks ago and in spite of the present financial depression the sum of £3600 was collected for the benefit of the charity. The Ambassador proposed the toast of "Le Corps Médical" and in thanking him on behalf of his colleagues Dr. George Ogilvie concluded by referring as follows to the hospitality which they had received in Paris: "Cette fête fut splendide, et nous fûmes reçus avec une hospitalité toute Française. Que dire de plus!"

EXPERIMENTS ON LIVING ANIMALS.

A RETURN showing the number of experiments performed on living animals during the year 1904 has been issued as a Parliamentary paper. In addition to the reports of the inspectors for England and Scotland and for Ireland, appointed under the Act, it contains lists of registered places, the names of licensees who performed experiments and of those who, though possessing certificates, did not perform experiments, and the number and the nature of the experiments. The total number of experiments performed in England and Scotland, both with and without anæsthetics, was 32,562, being 13,478 more than in 1903, the principal increase being in the number of simple experiments, such as inoculations, hypodermic injections, and some few other proceedings performed without anæsthetics. In Ireland there were 155 experiments which were for the most part inoculations or injections. Only 11 were of a physiological and 11 of a pathological nature. As the certificates differ in their nature and many licensees hold more than one certificate it is to be expected that there should be an occasional error of judgment on the part of the licensees but only the following cases occurred in England and Scotland while in Ireland there was none:—

1. A licensee, who held Certificate A for the performance of inoculation experiments without anæsthetics, made injections into two rabbits under a local anæsthetic. 2. A licensee, who held the necessary certificate, made injections into guinea-pigs for testing samples of milk at a registered place for which his licence had not been made available. 3. A gentleman, whose licence expired on Feb. 29th, performed ten inoculation experiments on mice before his licence was renewed. 4. A licensee, who held a certificate entitling him to perform eight such experiments, made inoculations for the purpose of diagnosis from eight cases of suspected disease into 17 rabbits. These must be counted as 17 experiments, in accordance with the principle laid down by the Secretary of State that the number of animals used shall not exceed the number of experiments allowed.

In each of the divisions of the United Kingdom the report states that the animals were always found to be suitably lodged and cared for, while the licensees acted in every way in accordance with the letter and spirit of the Act.

THE annual prize-giving of the London (Royal Free Hospital) School of Medicine for Women will take place on Thursday next, June 29th, at 4 P.M., when Mr. H. T. Butlin will present the prizes. The annual distribution of prizes to the students of the Medical School of St. Mary's Hospital will take place on the same day at the same hour. The prizes will be distributed by Sir John Gorst. The distribution of certificates and prizes at King's College, London, will be made by the Rev. James Gow, Litt.D., Headmaster of Westminster School, on Wednesday, July 5th, at 3 P.M. The museums and laboratories will be open to visitors.

THE Epidemiological Society of London will celebrate the fifty-fifth anniversary of its foundation on Friday, June 30th, when the annual dinner will take place at the Grand Hotel, Trafalgar-square, London, at 7.15 P.M. The President, Dr. B. A. Whitelegge, C.B., His Majesty's Chief Inspector of Factories, will take the chair.

THE Bishop of Ripon, chairman of the executive committee of the proposed National League for Physical Improvement, will give a dinner, "to meet the members of the League," at the Hotel Cecil, Strand, London, to-day (Saturday) at 7.30 for 8 P.M.

WE deeply regret to announce the death of Professor Mikulicz, the celebrated Austrian surgeon, at the comparatively early age of 55 years.

THE ARMY MEDICAL REPORT FOR 1903.[1]

FIRST NOTICE.

WE congratulate the Director-General of the Army Medical Service on having to submit to the Secretary of the Army Council a favourable report, which has just been published, on the health and the sanitary condition of the army for the year 1903. The report is a full and voluminous one and, as usual, includes records of the health of every home and foreign station where troops are serving.

If we remember aright it was Anthony Trollope who, regardless of the first principle of statistical science, jocosely remarked that he did not believe any statistics above six. And notwithstanding that statistical safety is only to be found in large numbers it must be confessed that to the general reader statistical reports—and these annual volumes are necessarily largely made up of statistics—can scarcely be regarded as a pleasant and diverting form of light literature. Still, there is much interesting information concerning the health of troops serving at home and abroad which can obviously only be obtained in this way. It is therefore necessary to deal with it and we shall strive to do so as succinctly as practicable and in close adherence to the report itself. In the first place, then, and as a broad, bald statement of fact, the average strength of European troops serving at home and abroad in 1903 was 242,182 warrant officers, non-commissioned officers, and men. The total number of admissions to hospital was 183,598, the total deaths were 1881, and the total number of men finally discharged from the service on account of disease and injuries was 4922. The admissions represent a ratio of 758·1 per 1000 of strength; the deaths one of 7·13 per 1000 on a strength of 263,888, which includes detached men not shown in the returns received. These ratios compare very favourably on the whole with those of the preceding year and with those for the decennial period from 1893 to 1902.

The troops serving in the United Kingdom in 1903 numbered 110,565. The admission, mortality, and constantly sick rates were 586·9, 3·41, and 35·23 per 1000 respectively. The report states, as in our opinion it is quite warranted in doing, that the admission-rate, seeing that the returns include all classes of sickness, both mild and severe, compares favourably with that of other armies, while the death-rate cannot be regarded as excessive when it is borne in mind that it is not merely a rate resulting from sickness originating in the United Kingdom but that the deteriorating effect of conditions of tropical service has also to be taken into account. The returns, moreover, include many diseases contracted during service abroad—and we need scarcely point out how serious and fatal these often prove to be. In these respects no real comparison can be made between the British and other armies. Taken as a whole the figures for 1903 make a good record, especially as compared with 1902, when the strength was less than in 1903. For England and Wales the admission- and death-rates show a decrease; in Scotland the admissions to hospital were less but the death-rate was higher; while in Ireland both rates were reduced.

---

[1] Army Medical Department Report for the year 1903. Vol. XLV. London: Printed for His Majesty's Stationery Office by Harrison and Sons, St. Martin's-lane [illegible] His Majesty. And to be purchased, either [illegible] y bookseller, from Wyman and Sons, Limited, [illegible] Oliver and Boyd, Edinburgh; E. Ponsonby, 116, Grafton-street, Dublin; or Eyre and Spottiswoode, London, E.C. 1905. Price 2s.

Only two cases of small-pox occurred in 1903 and the admission-rate for other eruptive fevers was lower than in the preceding year and as compared with the decennial average rate. There were 92 admissions and 28 deaths from enteric fever (a relatively high mortality). Aldershot had 27 cases and, as illustrating what we have already said, 16 of these are reported as having probably contracted the disease in South Africa or on the voyage home.

Turning to foreign stations and passing these rapidly in review, there is nothing calling for special attention at Gibraltar. At Malta the most noticeable point is that the prevalence of Mediterranean fever was much in excess of previous years; it caused 404 admissions, with nine deaths amongst the men, and 133 had to be invalided. 54 cases occurred amongst the officers, 21 of whom were invalided, while there were 70 cases amongst the women, with one death, and 33 cases amongst the children, also with one death.

In the South African command, with an average strength of 27,680, the admission, death, and constantly sick rates were 797·8, 11·06, and 60·03 per 1000 respectively. One [illegible] There were 145 cases of [illegible] been introduced into the [illegible] from England. Enteric [illegible] It caused 1155 admissions, 138 deaths, and the invaliding of 212 men. The disease shows, we are told, a regular periodic prevalence which is associated with the hot and wet season. Its prevalence usually begins in October and declines about May and invariably the fever is in almost complete abeyance during the dry cold weather of June, July, August, and part of September. The key to the prevention of the disease in South African experience, as in that of India, is to be found, the report says, in the *prevention of soil pollution.*

It is noteworthy that at Mauritius, in which colony plague was very prevalent during the later months of the year, only one case (the patient recovered) occurred among the European [illegible] ises amongst the non- [illegible] he troops in Ceylon was [illegible] for enteric fever.

Passing on to India, we are glad to call attention to the fact that the health statistics for the year were exceptionally [illegible] that for any of the [illegible] decrease in the [illegible] rates. The chief [illegible] venereal diseases. As regards enteric fever there was an increase in the [illegible] indeed to sanitarians generally.

In connexion with this we may refer the reader to the report "On the Health of the European Troops serving in India," *vide* pp. 219 to 252. There is no need to enter any further into this subject now. It suffices to say that the sources of infection are manifold and as having a close bearing on this subject the reader is referred to THE LANCET [illegible] review of the "Report on the [illegible] Fever in United States Military [illegible] r of 1898." Considering the very extended period during which the bacillus may be detected in the urine (typhoid bacteriuria) of those who have suffered from the disease, the infection is very difficult to be guarded against. In addition to the rigorous system of sanitation and hygiene enforced in the Japanese army and to the great attention paid to personal cleanliness, the Japanese soldiers are said to have recourse to creasote pills with which they are supplied on field service as a prophylactic, but whether their use has contributed to the relative immunity of the Japanese troops to enteric fever in the present war is more than we can say.

In the remarks on dysentery in India, which caused 1133 admissions and 42 deaths as compared with 1238 admissions and 44 deaths in 1902, it is stated that— [illegible]

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XVII.[1]

REFORM IN THE MEDICAL PROFESSION.

A Recapitulation of Prominent Grievances.—The Organisation of the Medical Profession.—The British Medical Association.—Local Medical Unions.—Medical Defence Associations.

THE object of writing these chapters has been to display the present state of the medical profession from a sociological point of view rather than to suggest methods of reform for admitted abuses, though in many instances the remedy for such admitted abuses has been pointed out. This has been done only when there was no doubt about either the existence of the evil or the procedure which should be used to combat it. The cause of reform generally, however, should be benefited by the bringing together of material for debate where subjects of dispute are touched upon, and by an attempt to appreciate the grievances of the medical profession at their proper value and to regard them with some sense of proportion. Although the main aim has been not to inaugurate any course of action so much as to furnish material upon which action can be taken, certain obvious directions in which reform should occur immediately may now be indicated. Most of them depend upon two things. Medical union is wanted—medical combination in an intelligent and liberal form, a professional union based upon the public needs and not a trade union directed towards the amelioration of a class as against the community. And a better understanding with the public is also sorely needed. When these tw [illegible] hat is now hard [illegible] and unj [illegible]

Take, for example, [illegible] ice in the navy, in the army, and in the Indian army. They can be altered at a moment's notice at the instance of the respective powers that be; all that is necessary is to convince those authorities that such alterations are advisable. Substantial improvements have been made in the conditions of employment in all three services of late, as has been shown, and it is necessary that allowance should be made for the things that have been done when the plea for more is put forward. It is impolitic as well as inaccurate to continue to speak as if no self-respecting medical man could accept commissions in the three services. Talk of this kind, as well as threats of boycotting, perpetuate and confirm the most unfortunate thing in the present position—viz., the social disadvantage under which the services seem to lie. It is a fact that the recent failure of a popular service club in London has been attributed openly to the action of the committee in electing medical officers. Consider the significance of such a statement even though it contains not a modicum of truth! It stands to reason that candidates for the services may be prevented by such stories from entering for commissions, which may be a very serious thing for the services, although there has been of late more competition to join them. The matter is one that is not much discussed in the medical press, for many who have the dignity of the profession at heart consider that in commenting upon the exclusion from clubs of medical officers undue stress is laid upon a mere act of snobbery, but I think no excuse is necessary for referring to it again here. The natural dislike of a young man to being reduced, through no fault of his own, to a position of social inferiority is one of the chief things that has kept commissions vacant, while the undermanning of the services, especially of the Royal Army Medical Corps, has been at the bottom of many of the troubles that have occurred of late years. It is no answer to the objectionable action of certain clubs to say that *if a medical man is a good fellow* he is never left out in the cold. Every other officer is admittedly the social equal of his brother officers *unless he is a very bad fellow*, which is a completely different thing. The situation, however, bids fair to be altered. Recently one of the best service clubs in London, at a special meeting, revised the ill-considered attitude of a previous election which had resulted in the exclusion of the medical officers, and there is good reason to suppose that this particular trouble is now over. It would never have occurred if the public, as represented by the army, had been in the least cognisant of medical aims and ideals and if the spokesmen for the Army Medical Service had kept those ideals in the van of their arguments. The various directions in which the warrants might be amended—nay, should in justice be amended—have all been mentioned in the chapter dealing with the military and naval medical service and there is not an alteration asked for that could not easily be granted. No opportunity should be lost by any member of the medical profession in pressing the just claims of the medical officers of the navy, the army, and the Indian army, but exaggerations and threats of boycott should be eschewed. The sense of the country is all in favour of a good medical service both in the army and the navy, and if the country could see that the civilian members of the medical profession were in complete sympathy with the equitable claims of the service members there would be less reluctance to reform on the part of the Government departments.

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., and XVI. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), May 6th (p. 1218), 13th (p. 1287), 20th (p. 1373), and 27th (p. 1449), and June 3rd (p. 1533), 10th (p. 1584), and 17th (p. 1657), 1905, respectively.

In a similar way, if the country and the Houses of Parliament could be made to understand that the difficulties of medical officers of health and Poor-law medical officers in different parts of the kingdom are not only very real but form sources of danger to the community at large those difficulties would soon receive attention. There is at the present moment before Parliament a little Bill[2] which has the support of the British Medical Association and which has two simple objects. It would insure that none but those properly qualified should be appointed as medical officers of health or sanitary inspectors, and it would give to all such officers and inspectors similar security in their tenure of office to that enjoyed by London medical officers of health. Security of tenure for medical officers of health and sanitary inspectors, so that the public health of the community may not be dependent upon the caprice of imperfectly constituted authority, would seem at first sight to be a measure of reform about which there need be no hesitation. There need not be any confirmation in office of unsatisfactory officials and there need be no difficulty about the removal of anyone who did not do his duty. No one suggests that the cause of sanitation demands such over-protection of medical officers; but to secure the public safety it is necessary that the executive officers should have a position commensurate in some degree with the importance and responsibility of their posts. The medical officers of health all over the country should be placed somewhat in the position which they enjoy in London—that is, they should be safe from individual spite and should be able to carry out a well-considered policy extending, it may be, over a term of years. No private interests of theirs or of anybody else should conceivably come between the public officers and their public duty. The community should see this, when Parliament would at once see it. The differences between the job work of the tradesman and the professional work of the sanitarian are not clear to the public but surely they could be made so if the medical profession were, as a whole, resolved that they should be.

The special grievances and drawbacks under which the medical profession labours in Ireland and Scotland can be removed at once by direct legislation aimed at patent abuses, but again the necessary prelude is unanimous opinion on the part of medical men. The eccentric subordination of the Scottish parish officers to a parish council and the harsh treatment of the Irish dispensary officers, who form nearly half the general practitioners of their country, are matters which require no further discussion to make clear the immediate necessity for their remedy. The Irish dispensary medical officer should have proper pay, proper pension, and proper treatment as a Government officer; the Scottish Poor-law medical officer should be fairly subsidised in the districts where subsidy is needed and should be protected from parochial tyranny. The position of education in Ireland, and the warring of the two great divisions of the Christian faith, produce in that part of the United Kingdom particular complications, and it must be recognised that the question of creed accounts for some of the difficulties in Ireland that may have only a professional aspect. It is rash to make any suggestion of reform here, for, in respect of Irish affairs, whoever does not agree with a proposition always considers its proposer an ass, and generally says so. However, it seems to me that the institution and subsidy of two new universities in Ireland would meet all the troubles due to the lack of higher education in that country. The need of a Roman Catholic University in Ireland arises from a feeling on the part of the Roman Catholics against the education of their children with the children of other faiths. The logicality of this feeling is much in dispute, but it is a strong and general one on the part of the majority of the inhabitants of Ireland and must be respected as such. The endowment of a university for the north of Ireland which, though nominally upon non-sectarian lines, would tend to become a Protestant institution must accompany the extension of privileges to the Roman Catholic community, and probably the course which would give the greatest satisfaction would be the re-establishment (as has been suggested by Sir William Whitla) of the old Queen's University in headquarters at Belfast.[3] The educational position arising out of the mixed religions of the community has been dealt with more or less successfully in Canada. In Ontario, where the majority is Protestant, and in Quebec, where the majority is Roman Catholic, good educational standards are obtained by a dual system. Why should politicians despair of obtaining the same in Ireland?

In all the circumstances so far alluded to, reform should follow immediately upon the definite action of a superior authority, whether it be Imperial Parliament, the War Office, or one of the Local Government Boards, having the desire to remove the abuse. And if the medical profession were properly organised, so that a common opinion upon many matters of medical politics were seen to be held, it would not be so difficult as it is to move Parliament or any constituted authority in the proper direction. A steady plea for justice, made with determination and moderation and backed by incontrovertible argument, has told already in several directions, but a unanimous expression of opinion from the medical profession would make the cause of reform much simpler. This, however, is lacking and it sometimes seems as if the medical profession were without a coherent view upon some of its most vital interests. A man may know what affects him personally in his professional life, but he seems never to appreciate that a similar thing may also affect his professional brother, while the medical men who do think about the conditions under which they work in something of a statesmanlike manner are rare. This is easy to understand, though it is none the less regrettable. Those who have few or no grievances cannot be expected to press for front places in the ranks of reform, and it happens that those who have few or no grievances are exactly those who would have most influence in obtaining redress, while those who suffer from the existing conditions have no time to make protest or no position from which to do so influentially. They possess no individual power and absence of organisation deprives them of the power of their numbers. Isolated members of this class see the immediate evil that threatens themselves and lift their voices in protest. But they do not see the troubles of other members of their own profession and they fail to take into account any general social factors that may be playing a part. Unbacked by any following of their own profession and unprepared with any arguments (save arguments that tell in favour of a limited class) why they should be listened to, they have no chance of effecting anything. Legislation will never be obtained for the benefit of medical men as a class, and no apology is needed for repeating this fact. What is good for the medical profession is good for the public, for it is to the public advantage to be served by a properly paid, properly organised, and self-respecting medical body. Demands for the redress of medical grievances on this ground will command weight, but here again it must be noted that neither the public nor Parliament can be stirred to the quick by generalities. It must be shown to Parliament that the public will be benefited certainly, and benefited primarily before legislation will occur, and to demonstrate these things requires organisation.

---

[2] THE LANCET, March 4th, 1905, p. 587.

[3] The University Question in Ireland, by Sir W. Whitla, M.D. Irish University Education, by William Delany, S.J.

The medical profession is not, of course, entirely without organisation, and there are grounds for thinking that its power for safeguarding its interests is growing. The British Medical Association was newly constituted in 1902 with the distinct intention of forming a more vital medium of union between members of the medical profession, and sufficient time has not yet elapsed to show how far this intention will be fulfilled. By the new articles of the Association the central government is kept ingeniously in touch with the whole constituency, and representatives, whose travelling expenses are paid by the Association, can make the wants of medical men in all parts of the country known to the centre. That is to say that the British Medical Association in its present shape possesses a fine fighting machinery. Take, for example, the question of contract practice. If a member of a division of the Association intimated through that division to the branch of which it formed a part, and so to the council of the Association, that he was resigning a certain post because the conditions of tenure were unprofessional, it would be possible for the Association to ostracise all members of the Association who accepted the post which had been resigned. Again, every branch might constitute itself into a court of honour and so a system of ethical conduct might be evolved. The British Medical Association is in short a powerful combination. It has numbers, it has a sound working scheme, and all its members are, perforce, educated people who do not hanker after trade-union methods, but who merely desire the fair treatment that will enable them to do their work under proper conditions. With all these advantages we are right to expect great things from the British Medical Association in the direction of reform, but the body of members, if their attitude at general meetings may be taken as a criterion, are not yet sufficiently interested in the matter. They have, perhaps, not yet learned the powers of the body to which they adhere.

In the meantime a fair number of medical unions have been called into being with a view of establishing a consensus of professional opinion upon such matters as contract practice. Their members have perceived the conditions and the necessity for combined action. It is important that these societies should not cease from their task, although in the future the British Medical Association may be in a position to supersede them. At the present moment it is conceivable that the very completeness of the scheme of the Association is against its smooth working in the case of local troubles. The all-important thing in local troubles is speedy action, while the developments of the Association are towards a concentration of responsibility at headquarters which usually leads to delay. The time may come when the branches or divisions of the Association may be so familiar with the details of medical defence, with the methods of sanitary authorities, and with the aims of medical-aid associations as to be able to muster with promptitude behind an injured practitioner the full force of the Association. But at the present time this is not what occurs, and much of the work of protecting the practitioner from the effect of unfair competition has fallen upon local organisations.

In one direction the members of the medical profession can make use of machinery that has been ably and successfully planned for their protection. There exist in the Medical Defence Union and the London and Counties Medical Protection Society means whereby medical men can secure themselves against unjust treatment at the hands of the public, while the disciplinary functions of the General Medical Council can be assisted at the same time. Each of these two bodies is excellently managed and each has met with distinct and meritorious success in championing oppressed medical men. The ease with which accusations against the moral character or professional skill of medical men can be made is well known and swiftly perceived by all with a taste for *chantage*. To read the annual report of each of the two associations is to see how manifold are the risks which the medical man runs at the hands of the unscrupulous in the daily work of his life, while the many cases of triumphant defence prove that against organised resistance the tactics of the blackmailer are almost bound to fail. The Medical Defence Union and the London and Counties Medical Protection Society, covering the same ground in their efforts and located in the same city, would probably gain in utility to their clients by amalgamation, and such a fusion of funds and interests has long been debated as a policy that would make alike for economy and effectiveness; but, though the joint work that the two societies could do might more than double the total that they now accomplish separately, the value of their labours must not be belittled on this account. These two societies represent the best corporate attempt in the medical profession to deal with existing hardships, and the fact that they have been able to do so with a large measure of good fortune shows how much might be achieved by corporate effort of a more general character.

One of the principal objects of the change in the constitution of the British Medical Association was to place at the service of the medical profession an institution which should combine the advantages of a local medical society with those of an imperial organisation. The probability is that in time this object will be realised, but the present is a period of interregnum and only such already existing local societies as feel that they have not accomplished their aims are likely to exterminate themselves before seeing that the Association will be willing as well as able to fight their battles for them. There are several local societies which watch over the interests of their members with keenness and success. None of them is a particularly strong or influential body, but all have the merit of being prompt to act and familiar with the situations that may arise in the locality. I may mention, for example, the Northumberland and Newcastle Medical Association which has secured for medical men the respectful attention of mine-owners and miners who had previously regarded them as fair game for exploitation. Reform, if the word is to imply doing rather than talking, for the present depends, it seems to me, upon the multiplication of such bodies. This does not imply the creation of a crowd of new associations. In every populous centre the medical society—there is always such a body—should be prepared to deal with ethical questions and might be erected into an authority to decide upon professional matters. This would in no way change the character of the society as a scientific body, for the political and scientific sides could be kept apart in their working, while each would gain by the union. Thus, each section of the medical profession would become familiar with the needs of other sections, the stupidity of dissension would become patent, and the public would range itself on the side of well-founded demands for reform. Then reform would follow.

(To be continued.)

EPSOM COLLEGE.

A BRIEF ACCOUNT OF ITS FOUNDATION IN 1851, WITH PARTICULARS CONCERNING THE BENEVOLENT AGENCIES OF THE PROFESSION FROM 1840 TO THAT DATE.

IN view of the celebration of the jubilee of the opening of Epsom College on July 1st, when the council and the head-master will entertain a large party of old Epsomians at the College, our readers will no doubt be glad to have a brief sketch of the foundation of the College by Mr. Propert in 1851 and of the efforts made for some years before to inaugurate institutions to transact the two branches of work which are now so successfully carried out by the College—namely, the provision of a first-rate education for the sons of medical men at a moderate charge and the relief of medical men and their families when in distressed circumstances. Many old boys who were present at the opening of the College, or who went there very soon afterwards, have accepted the council's invitation and it is easy to imagine the satisfaction which they will experience at calling to mind the buildings of their time which were just sufficient to accommodate 150 boys and stood in about 17 acres of land, whilst comparing them with the numerous buildings now standing in close upon 80 acres of land, comprising the hostel, a lower school to accommodate 100 junior boys, a head-master's house, a chapel providing 380 seats, three laboratories, a very large swimming bath, a carpenter's workshop, a reading and art room, a lecture theatre, a detached sanatorium, a library, and a gymnasium.

To take as a starting point the year 1840, there were at that time numerous medical benevolent agencies in existence, the most important of which was the Society for the Relief of Widows and Orphans of Medical Men. Having been in existence 57 years it possessed in 1845 217 life members and 126 annual subscribers and was giving assistance to 35 widows of deceased members and to 22 of their children. The British Medical Benevolent Fund was established as the "Medical Benevolent Fund" in 1836, but the scope of its work in the early days was very restricted, the receipts for the year 1841-42 being only £202 and the disbursements £56. The Surrey Medical Benevolent Society, founded in 1812, had from the first been judiciously managed, the result being that it possessed in 1855 funds amounting to £5500, at which time the claims upon the society did not exceed one-eighth of its income from dividends. Its committee therefore negotiated the purchase of four scholarships at the College in order to further the objects of the society. The "Medical Benevolent Society for the Town and County of Leicester" was founded in 1788, but no meetings having been held since July, 1818, and as no claims had for many years been made the trustees handed over to the College the residue of their funds. There were also the Devon and Exeter Benevolent Medical Society; the Birmingham Medical Benevolent Society, established in 1821; the Essex and Hertfordshire Benevolent Medical Society, founded so far back as 1786; the Kent Benevolent Medical Society, established one year later; the Lincolnshire Medical Benevolent Society, founded in 1804; and the West Riding of Yorkshire Medical Charitable Society, founded in 1828.

In 1844 a committee was appointed at the annual meeting of the Provincial Medical and Surgical Association, which was the title of the British Medical Association prior to 1854, to consider the establishment and organisation of schools for the education of sons of members of the medical profession on such low terms of expense as might be consistent with a course of education of a high character. The committee, which was requested to lay its proposals before the council of the Association or before the next general meeting of the members, consisted of Dr. Forbes, Dr. Kerr, Dr. Heygate, Dr. Edwards, Dr. Hodgkin, Dr. Hardwick, Dr. Budd, Mr. Hodgson, Mr. Nunneley, Mr. Daniell, Mr. Wallace, and Mr. Martin. Dr. Forbes of London was appointed chairman and Mr. Thomas Martin of Reigate secretary. The appointment of the committee took place at Northampton, but it was found that most of the members were too far apart from each other to admit of convenient meetings being held, hence it was decided to form a subcommittee of those gentlemen residing in or near London—namely, Dr. Forbes, Dr. Hodgkin, Dr. Hardwick, Mr. Wallace, and Mr. Martin, any subjects of great importance to be laid before those members living at a distance by letter. The salient features of the scheme which was eventually proposed were as follows:—that a sum of £10,000 should be raised in shares, donations, and benefactions; that at first only one school, to educate from 200 to 300 boys, should be established in London; that pupils should be admitted by nomination only, the sons, grandsons, nephews, or wards of members of the medical profession to be admitted at the charge of 30 guineas per annum for board and education, with an entrance fee of £3 3*s.*; other boys to be admitted at the annual charge of 40 guineas, with the same entrance fee, but the latter not to be nominated in a larger proportion than one in three; that the government of the institution should be in the hands of a council consisting of 24 medical men, the members to continue in office three years and to retire in sections of thirds, but to be immediately eligible for re-election; and that the annual meetings of shareholders and donors should be held in London, at the school, or wherever the council might consider to be most eligible.

In presenting the scheme to the members of the Provincial Medical and Surgical Association and to the profession generally, the committee observed that it entertained no misgivings as to the probabilities of its being successfully carried out and it appended to its report the names of 12 subscribers and benefactors as follows: Dr. A. Robertson, £100 donation; Mr. E. Daniell, one share of £25; Mr. Thomas Martin, one share of £25 and £100 donation; Mr. J. Hodgson, £100 donation; Sir Benjamin Brodie, Bart., £100 donation; Dr. John Forbes, £100 donation; the Misses Wallace, £25 benefaction; Mr. Edward Wallace, one share of £25 and £20 benefaction; Dr. A. Hardwick, £20 donation; Sir James Clark, Bart., £100 donation; Mr. T. Nunneley, one share of £25; and Mr. P. J. Martin, £25 donation. It may be added that the first idea of the committee was to raise the whole sum by means of shares only, but finding that there were strong objections against this plan in the minds of some it proposed the alternative in the form of donations. The class of benefactions was created for those who did not wish to incur the responsibilities and duties of the shareholders and donors. This report, signed by the chairman and the secretary, was dated Dec. 26th, 1844, but in spite of the generous offers referred to the scheme eventually fell through. It is interesting to note, in view of statements which have been made that Mr. Propert intended Epsom College to be exclusively for the sons of medical men, that in this scheme, proposed some years before the initiation of the College, it was intended that more than one-third of the boys should be sons of those not members of the medical profession.

The General Medical Annuity Fund.

In the following year Mr. Edward Daniell of Newport Pagnell delivered an address at Sheffield on the thirteenth anniversary of the Provincial Medical and Surgical Association containing proposals for establishing a General Medical Annuity Fund for disabled members of the medical profession, their widows and orphans, and at the conclusion of his speech proposed the following motion which was seconded by Dr. Robertson of Northampton and carried unanimously:—

> That a committee of the Association be appointed immediately to consider, discuss, and arrange the best preliminary steps for the establishment of a self-supporting institution connected with the Provincial Medical and Surgical Association, to be called an "Annuity Fund for Decayed Members of the Association and for Widows and Orphans of Members."

The first meeting of the committee was held on Sept. 8th, 1845, when there were present: Dr. A. Robertson (in the chair), Dr. W. Kerr, Mr. E. Daniell, Mr. H. Terry, Mr. John Faircloth, Mr. Robert Ceely, and Mr. John G. Appleton. It was ultimately resolved to establish a fund for the payment of annuities to superannuated or disabled members of the medical profession, their widows and orphans, the title of the institution to be "The General Medical Annuity Fund," the appointment of officers to be vested in the Provincial Medical and Surgical Association. It was decided that an annual subscription of one guinea should entitle a legally qualified medical man in the United Kingdom to become a member of the Fund and at the expiration of the fifth consecutive year of his subscription such member, or his widow or orphans, would become eligible to receive an annuity. For every 100 subscribers there were to be three annuities, not exceeding £25, for superannuated or disabled members, and three annuities, not exceeding £15, for widows and orphans. It was decided that the directors of the fund should report the general state of the affairs of the institution at the annual meeting of the Provincial Medical and Surgical Association, and that elective members should consist of not fewer than ten members of the Provincial Medical and Surgical Association, of whom not fewer than four were to be resident in the district where the annual meeting of the Provincial Medical and Surgical Association was to be held. The officials selected were as follows:—President: Dr. Charles Fox Favell. Treasurer: Dr. Archibald Robertson. Managing Director: Mr. Edward Daniell. Elective managers: Mr. Richard Faircloth, Mr. J. G. Appleton, Mr. J. G. Crosse, Mr. Thomas Paget, Mr. Francis Elkington, Dr. William Budd, Dr. Charles Cowan, Dr. Edward Holme, Mr. Peter Martin, and Mr. W. Kent. Secretary: Mr. Joseph Staines (Newport Pagnell).

By the end of the second year some modifications of the rules were made. It was decided that a subscription paid in advance for 20 years, or a donation amounting to 20 guineas, should constitute the subscriber a member for life and that for every 100 subscribers the directors should grant four annuities of £25 each; but it was provided that no member or his widow or children should be eligible for an annuity unless the subscriber had been a member of the society five years from the payment of his first subscription. Ultimately the society was severed from the Provincial Medical and Surgical Association. Although in the course of four years from the foundation of the society Mr. Daniell obtained 182 subscribers and received a considerable sum in donations it was acknowledged that he had failed in carrying out his object in founding the society to any practical purpose. As its severance from the Provincial Society rendered the remodelling of the fund necessary, apart from the fact that it was difficult to carry on the work in the country, and ascertaining that there were some practical defects in the original plan, Mr. Daniell resigned the direction of his society in 1849. A committee was appointed to place the institution on a new basis and in October of that year a new title, "The National Medical Annuity and Relief Fund Society," was proposed, but it was ultimately decided in July, 1850, to adopt the designation, "The British Medical Fund, a Provident and Relief Society for Medical Men, their Widows and Orphans." The institution was enrolled as a benefit society, Mr. Hawtayne was [illegible] members of the society to assure for themselves deferred annuities, to effect assurances upon their lives in sums not exceeding £200, to afford the means of securing for themselves a certain weekly provision during sickness or other bodily or mental infirmity, and to secure a definite annual provision by way of maintenance for their widows or children. The object of the relief branch was to provide by donations, subscriptions, bequests or otherwise, a fund for the purpose of granting temporary or permanent relief to persons who were or had been members of the society, or to their widows or families. Sir Benjamin Collins Brodie, Bart., was elected President and the following were appointed directors: Dr. John Forbes (chairman), Dr. J. R. Bennett, Mr. J. Bird, Mr. T. B. Curling, Mr. H. Hancock, Mr. E. Headland, Mr. J. Propert, Dr. E. H. Sieveking, Dr. J. Spurgin, Mr. G. J. Squibb, Mr. S. Stedman, and Mr. T. Taylor.

In spite of the carefully thought out programme and of the unremitting efforts of the directors the society was doomed to failure. Members of the profession generally did not avail themselves of the advantages offered by the society; there can be no doubt that the lack of a substantial reserve fund was an important factor in its failure and perhaps the ambitious programme of the reconstructed society had a share in its failure, since its rules, tables, &c., filled 40 octavo pages. Nevertheless, the directors had faith in their scheme, for in their report submitted to the special meeting of members on June 2nd, 1852, at which the society was dissolved, they wrote as follows:—

> [illegible] and vigour.

Commenting on the directors' report the *Medical Times and Gazette* of June 12th observed:—

> Judging from some statements in the report we should imagine that, if the sum of £2000 could be at once subscribed, it would be sufficient to accomplish the great end in view.

The London and Provincial Medical Protection and Benevolent Society.

It was probably about 1847 or 1848 that a society was founded under the above title, the objects of which were to create a higher tone in the public mind towards the medical profession and to secure the more regular payment for professional services from those who possessed the means but not the disposition to remunerate medical men. There was also a proposal to establish a fund to be devoted to the erection and support of a college for the education of the sons and daughters, orphans or otherwise, of medical men and also to provide houses for the reception of distressed members of the medical profession or their widows. Mr. Propert consented to be its president; the bankers appointed [illegible] eet-street, E.C.; [illegible] Robert Gosling; [illegible]; Mr. T. Ballard, Mr. A. B. Barnes, Dr. Adolphus Barnet, Mr. T. T. Campbell, Mr. F. Clarke, Mr. G. W. H. Coward, Dr. W. Crellin, Mr. R. Dunn, Mr. R. Edgcumbe, Mr. George Fincham, Mr. F. Godrich, Mr. G. Harwood, Mr. J. Ince, Mr. F. G. Johnston, Mr. C. F. J. Lord, Dr. W. Major, Mr. W. C. Meates, Mr. S. Pearce, and Mr. J. Sharp.

In an article which appeared in THE LANCET of April 5th, 1851, the history of this unfortunate society was given. It seems that Mr. Propert lent the influence of his name in every legitimate manner to forward the interests of the institution and, as he believed, of the great body of its members, having full confidence in the integrity of the immediate movers of the scheme. But the society proved to have been mismanaged and the liabilities of the conductors were great, the result being, as might be expected, the irretrievable ruin of the institution. With great generosity Mr Propert undertook to pay out of his own pocket all debts due to members under £10 in amount. The investigation of the accounts of the defunct society brought to light the fact that one of the causes of the impoverished condition of medical men was their inability to obtain payment of their accounts. When it is stated that the books of this single society showed that the enormous sum of considerably over a quarter of a million was due to its members for unpaid debts, it will be seen that there was certainly scope for the foundation of a school where the sons of medical men could obtain efficient education at a lower rate than that charged by the leading public schools of England.

It was on the failure of this society that Mr. Propert contemplated the foundation of Epsom College and in an article which appeared in THE LANCET of April 5th, 1851, an extract from which is given below, the matter was referred to; in fact, this was the first notice of the proposed College which appeared in the press; but at that date Mr. Propert had not definitely settled the details of his scheme. The Editor wrote as follows:—

> Could the veil be uplifted fron [illegible] of the now humble homes of thos [illegible] though now widowed and orphane [illegible] the scenes presented would quail [illegible] the history of a country surgeo [illegible] eloquence in the *Times*, in conne [illegible] that picture, far from being overcharged, might have been painted in still darker colours. The after-history of such a family, particularly where there are six or seven, instead of two children, would be too painful to dwell upon. Honour, then, to those who would avert such calamities! And especially at this time would we do honour to the efforts that are being made by that most respectable member of our profession, Mr. Propert, to establish an institution to remedy the evils of which we have spoken

With regard to the reference to the "iniquitous income-tax" it will be remembered that this tax was reimposed by Sir Robert [illegible] een in abeyance for 26 years; [illegible] was imposed on all incomes exc [illegible] practitioners, with their heavy necessary expenses, bad debts, and unpaid accounts, were probably more affected by the tax than members of any other profession.

The scheme for the establishment of Epsom College, as foreshadowed in this article, was somewhat indefinite, for reference was made to a school for both the sons and daughters of medical men, and it was implied that the College would be to some extent a reconstructed medical protection society with a debt-collecting department. However, Mr. Propert must have lost no time in applying himself to the details of the proposed institution for within one month he had definitely settled his scheme and it has ever since been carried out on the broad lines then decided upon—namely, a school for the sons of medical men and others, the former to be educated and maintained at as moderate a cost as possible, and the support of pensioners. In the early part of the nineteenth century the favourite mode of maintaining pensioners was to provide them with furnished apartments in almshouses, yet it is surprising that a long-sighted man like Mr. Propert, who succeeded in launching an institution when, as we have seen, others had laboured indefatigably but failed, did not see the incongruity of placing the failures of the profession permanently before the eyes of schoolboys, many of whom would aspire to follow that profession. In an article in the *Provincial Medical Journal* in 1851 attention was drawn to the fact that objections had been raised to the idea of almshouses as being degrading to the medical profession. Referring to Mr. Propert's scheme, the Editor of THE LANCET on May 3rd, 1851, wrote as follows :—

> We highly approve of the plan of supporting a number of medical pensioners, but we give our special support to the collegiate department of the proposed institution. The school for "the education and maintenance" of the sons of medical men ought to entitle the proposed college to the support and peculiary contribution of every legally qualified medical practitioner in the kingdom.

Another extract from this article will prove of special interest to old Epsomians and others who for many years wished the title to be changed from "The Royal Medical Benevolent College," an alteration which was effected at a special general meeting of the governors in 1903.

> We wish, then, the proposal of Mr. Propert good speed. We should like to see the term "Benevolent" omitted from the title, but for the objects of the institution, whether for eleemosynary or educational purposes, we have but one word and one thought, that of hearty cooperation and support.

There are probably few persons living now who were present at the general meeting of members of the medical profession and others which was held at the Hanover-square rooms on Wednesday, June 25th, 1851, under the presidency of Earl Manvers, to consider the propriety of establishing a "Medical Benevolent College." A complete list of those present on that occasion does not appear to have been preserved but the following were amongst those who attended: Dr. Aldis, Dr. Allison, Mr. John Bowling, Mr. Henry Cancellor, Mr. Nathaniel Clifton, Mr. Benjamin Bond Cabbell, M.P., Dr. John Forbes, Mr. James William Freshfield, M.P., Mr. George J. Guthrie, Mr. Henry P. Fuller, the Rev. Thomas Garnier, Sir Robert Harry Inglis, Bart., the Rev. J. Jennings, the Rev. David Laing, the Bishop of London, Mr. Charles F. Lord, Sir Thomas Phillips, the Rev. George Pocock, Mr. John Propert, the Bishop of Ripon, Dr. Spurgin, and Dr. James Arthur Wilson. In his address to the meeting Mr. Propert adverted to the many cases of distress which existed in the medical profession and in families of medical men deceased, arising in many instances from premature widowhood and other contingencies which were peculiar to the profession, and having informed the meeting of the principles upon which it was proposed that the Medical Benevolent College should be founded he briefly alluded to the success which had up to that period attended his exertions in furtherance of the object. He pointed to the benefits likely to follow the establishment of such an institution and appealed to the public and to the profession in its support.

At the conclusion of Mr. Propert's speech, it was moved by the Bishop of London, seconded by Sir Robert Harry Inglis, Bart., and resolved unanimously :—

> That this meeting, under a sense of the claims of the medical profession upon the public at large, hereby declares the formation of the Medical Benevolent College on the plan suggested by John Propert, Esq., and pledges itself to promote its success by every means in its power.

Earl Manvers consented to accept the office of President, Mr. Robert Gosling was appointed treasurer, and it was decided that the council should consist of the President, the vice-presidents, and 26 gentlemen appointed at the meeting. The public initiation of the College having taken place Mr. Propert lost no time in organising his enthusiastic band of workers. A few months after the initiation of the College a rumour became current that it was to be essentially a "class" school and as this was contrary to the intentions of the founder and was likely to be prejudicial to the success of the institution the council lost no time in contradicting the rumour through the columns of THE LANCET. In the issue of Nov. 29th, 1851, the Editor wrote as follows :—

> It has gone abroad as an objection to the scheme that the school will not only be exclusively for the sons of medical men but for those sons only who are intended for the profession. The idea is monstrous. We have authority for stating that the school will not be confined to the sons of medical men but the foundation will be exclusively for the orphans and sons of distressed members of our own profession, whatever be their future destination, and that they will be educated in a manner to fit them for first rate mercantile pursuits, Government offices, or any of the professions or respectable trades.

Those who were present at the special general meeting of the governors in November, 1903, when the title of the institution was changed to "Epsom College," will recollect that a letter was read from Mr. John Lumsden Propert giving his views as to the intentions of his father in establishing the College. It is remarkable how closely these views approximate to those held by the founder as expressed in the article quoted above. But though money came in freely it was not without unremitting work on the part of friends throughout Great Britain. The lack of interest which proved fatal with other medical benevolent societies was conspicuous in the case of the College and in commenting on this THE LANCET frankly stated in its issue of Jan. 3rd, 1852, that at the outset of the scheme many medical men doubted its final success and therefore declined to attach their names to what they conceived to be a failing cause. This hesitation was but natural, since both the London and Provincial Medical Protection and Benevolent Society, which had failed, and the reconstructed General Medical Annuity Fund, which was wound up in 1852, had enjoyed the support of some of the most eminent men in the profession. THE LANCET therefore appealed to those who had not so far come forward to permit their names to be added to the list of contributors and the appeal evidently bore fruit, for in the issue of Feb. 7th, 1852, it was stated that the final success of the College could not be doubted in any quarter, its failure being no longer a possible contingency. Between £6000 and £7000 had already been collected and subscriptions were pouring in every day and almost every hour. Local secretaries were multiplying—volunteer collectors were starting up in every part of the country and some who had been once cold, cautious, and doubtful had become warm and zealous.

On Dec. 1st, 1852, the council formally took possession of the land at Epsom, on which occasion there was a gathering of friends. After the ceremony the party proceeded to the Spread Eagle Inn, where about 80 sat down to dinner. Mr. J. W. Freshfield, M P., was in the chair, Mr. John Propert, who had succeeded Mr. Gosling as treasurer, was vice-chairman, and amongst the company were the Rev. G. Pocock Dr. Conolly, Dr. Cooke, Dr. Sieveking, Dr. Gibson, Dr Goodfellow, Dr. Tuke, Dr. Price, Dr. Power, Dr. Semple Mr. H. Pownall, Mr. N. Clifton, Mr. G. T. Dale, Mr. W Self, Mr. John Lewis, Mr. R. D. Edgecumbe, Mr. Joh Chippendale, Mr. G. Fincham, Mr. S. Roots, Mr. G. Pilche Mr. T. Hunt, Mr. W. Carr, Mr. C. F. J. Lord, Mr. W. C Meates, Mr. Robert Dunn, Mr. John Ince, Mr. Georg Curtiss, Mr. J. F. France, Mr. P. Martin, Mr. W. Hart, M W. T. Iliff, Mr. J. Churchill, Mr. John Harris, Mr. E. Clifto Mr. T. J. Ryder. Mr. G. W. Driver, Mr. H. T. Davies, Mr. F Crew, and Mr. T. F. Clarke.

On July 6th, 1853, the President, Earl Manvers, very kindl undertook to lay the foundation-stone of the College at a fe hours' notice. His Royal Highness Prince Albert ha graciously promised to perform that function and in view c the Royal visit triumphal arches had been erected and a ver large gathering of friends of the institution had assemble But about 4 o'clock a rumour was circulated that His Roya Highness could not attend and shortly afterwards M Propert read to the assembled visitors the following lette from Colonel Grey :—

> Buckingham Palace, Wednesday, July 6th, 1853.
>
> DEAR SIR,—I regret to have to write to you, by command of th Prince, to say that it will be quite impossible for him to attend th ceremony to-day for laying the first stone of the Medical College. H regrets much the disappointment this may occasion to the promoter of this institution and was anxious himself to make every effort t attend, but His Royal Highness has a severe attack of indispositio and his medical advisers are peremptory in their directions, that h should not think of leaving the Palace.

The numerous ladies present showed their interest in th College by presenting the sum of £1600 in donations of fi guineas each.

On Sept. 6th, 1853, the contract for the building wa signed, all legal arrangements having been duly made. I was originally proposed to build almshouses for 100 pensioners but the impracticability of providing accommodatio for this large number was evidently realised in course o time, for 24 residences was the largest number built and te years elapsed before even all these were erected. At th annual festival dinner held on Feb. 27th, 1855, the followin letter was read announcing that Her Majesty the Queen ha graciously extended her patronage to the College :—

> Buckingham Palace, Feb. 27th, 1855.
>
> DEAR SIR,—I have had the honour to submit to Her Majesty th Queen the purport of the conversation which I had with you th morning with respect to the Medical Benevolent College and I have th pleasure to inform you that Her Majesty has been pleased to grant he patronage to the College and to approve of the alteration of its designation to that of the Royal Medical College.—Yours truly,
>
> C. B. PHIPPS.
>
> To John Propert, Esq.

Was it by accident or by design that Colonel Phipps omitte the term "*Benevolent*" in mentioning the new title of th institution which had been approved of by Her Majesty? I the first part of the letter to Mr. Propert he referred to th institution by its existing title "The Medical Benevolen

College" but at the conclusion he clearly stated that the Queen had approved of the alteration of its designation to that of "The Royal Medical College."

It should be mentioned that Mr. Henry Tudor Davies rendered invaluable services as honorary secretary in these early days of the College and both Miss Propert and her sister, Miss Harriet Propert, laboured incessantly in assisting their father. Mr. Davies was succeeded by Dr. Edward H. Sieveking in 1853, who continued in office until 1856, when Mr. Robert Freeman was appointed secretary. The first office of the College was at 4, Hanover-square, but in September, 1853, it was removed to 37, Soho-square, W., so that the council has held its meetings for over 50 years in the present handsome room facing Soho-square.

On June 25th, 1855, the ceremony of opening the College was performed by His Royal Highness Prince Albert who was accompanied by H.R.H. the Prince of Wales (His present Majesty the King). Prince Albert was attended by the Marquis of Abercorn, Colonel the Hon. C. B. Phipps, Captain the Hon. de Ros, and Sir James Clark, and having been received at the entrance porch by the officers and council His Royal Highness was conducted by Earl Manvers, Mr. Propert, and Mr. Hancock to an apartment prepared for his reception. The proceedings of the formal opening commenced at the entrance of the building where the following address was read by the Bishop of Oxford:—

Royal Highness is aware, by the voluntary subscriptions of many connected with the Medical Profession, who know and feel for the

with all who suffer, and believe that you are in this especial case further not unwilling to testify your gratitude to that Profession which aims, with God's blessing, at removing disorders and relieving suffering from which, in this world of sorrow, the highest in virtue and the most elevated in rank can claim no more exemption than the poorest or least worthy of the common family of man. May God abundantly return into your own bosom the kind assistance you have this day rendered to us!

To this address His Royal Highness replied in the following terms:—

[illegible] back to their families.

The Bishop of Winchester then read a psalm and offered up prayers, after which His Royal Highness formally declared the Royal Medical Benevolent College to be opened. He was then conducted over the principal parts of the building; on returning to the reception room he received the company assembled, and soon after 5 o'clock the Royal party left. About 500 visitors partook of a *déjeuner*, at which Earl Manvers presided. After the loyal toasts had been enthusiastically received and the toasts to the Army, Navy, Bishops, Clergy, and Chairman had been drunk, Mr. J. Lloyd Davies, M.P., proposed the health of "The Founder." Mr. Propert's reply, as under, cannot fail to be interesting, and it is needless to say that on rising he was repeatedly cheered:—

I am quite sure that the warmth of human kindness which has brought you here to [illegible]

[illegible] our profession, to console the afflicted widow, and to rescue bereaved orphans from the bonds of indigence and want, and to put them in a way of procuring a livelihood so as to be a credit to themselves and an ornament to society. When I look back upon what has been done I cannot find words to thank you for your kind support to the undertaking. There is one circumstance connected with the day's proceedings of which I cannot but feel proud, and that

rising to its present position. You have all done your duty—and I hope and trust that our building will endure and be a blessing to generations yet to come.

After some other toasts the party adjourned to the dining hall, where, as the report of the day's proceedings states, dancing was enjoyed until the time arrived for the departure of the special train. Thus ended the day of the opening of Epsom College, the jubilee of which will be celebrated on July 1st.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7437 births and 4016 deaths were registered during the week ending June 17th. The annual rate of mortality in these towns, which had been 14·6, 14·7, and 13·5 per 1000 in the three preceding weeks, further declined last week to 13·4 per 1000. In London the death-rate was 13·3 per 1000, while it averaged 13·5 in the 75 other large towns. The lowest death-rates in these towns were 5·1 in Handsworth (Staffs), 5·1 in Leyton, 5·6 in Hornsey, 6·6 Ipswich, 8·0 in East Ham and in Great Yarmouth, 8·1 in Devonport, 8·2 in Brighton, and 8·5 in Croydon; the highest rates were 17·0 in Middlesbrough, 17·1 in Birkenhead, 17·3 in Newcastle-on-Tyne, 18·5 in Preston, 19·1 in Merthyr Tydfil, 19·8 in Sunderland, 20·5 in Wigan, 22·5 in Barrow-in-Furness, and 23·3 in Tynemouth. The 4016 deaths in these towns last week included 355 deaths which were referred to the principal infectious diseases, against 414, 410, and 413 in the three preceding weeks; of these 355 deaths, 134 resulted from measles, 77 from whooping-cough, 66 from diarrhœa, 32 from diphtheria, 25 from scarlet fever, 19 from "fever" (principally enteric), and two from small-pox. In Croydon, Hornsey, Portsmouth, Walsall, Rochdale, Blackburn, South Shields, and in eight other smaller towns, no death from any of the principal infectious diseases was registered; while they caused the highest death-rates in Hanley, West Bromwich, Coventry, Warrington, Barrow-in-Furness, and Middlesbrough. The greatest proportional mortality from measles occurred in Walthamstow, West Bromwich, Coventry, Birkenhead, Warrington, Barrow-in-Furness, Sheffield, and Merthyr Tydfil; from whooping-cough in Middlesbrough and Tynemouth; and from diarrhœa in Middlesbrough and Rhondda. The mortality from scarlet fever, from diphtheria, and from enteric fever showed no marked excess in any of the large towns. One fatal case of small-pox was registered in Derby and one in Preston, but none in any other of the 76 towns. The number of small-pox patients remaining under treatment in the Metropolitan Asylums Hospitals, which had been ten, nine, and nine on the three preceding Saturdays, had further declined to seven on Saturday last, June 17th; three new cases were admitted during the week, against one and three in the two preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2200, 2268, and 2285 at the end of the three preceding weeks, had further risen to 2356 at the end of last week; 292 new cases were admitted during the week, against 312, 351, and 269 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 218, 235, and 191 in the three preceding weeks, further declined last week to 189, but were 47 above the number in the corresponding period of last year. The causes of 49, or 1·2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Leeds, Newcastle-on-Tyne, and in 47 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, St. Helens, Manchester, Sheffield, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·1, 16·9, and 16·4 per 1000 in the three preceding weeks, further declined to 15·7 per 1000 during the week ending June 17th, but was 2·3 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·6 in Leith and 12·5 in Aberdeen to 18·3 in Paisley and 24·4 in Perth. The 528 deaths in these towns included 29 which were referred to whooping-cough, 26 to measles, 15 to diarrhœa, two to "fever," one to scarlet fever, and one to diphtheria. In all 74 deaths resulted from these principal infectious diseases last week, against 76, 80, and 62 in the three preceding weeks. These 74 deaths were equal to an annual rate of 2·2 per 1000, which was 1·0 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 24, 24, and 23 in the three preceding weeks, rose again to 29 last week, and included 14 in Glasgow, eight in Edinburgh, five in Paisley, and two in Dundee. The deaths from measles, which had been 33 and 17 in the two preceding weeks, rose again last week to 26, of which 16 occurred in Glasgow, eight in Edinburgh, and two in Perth. The fatal cases of diarrhœa, which had been 16 and 14 in the two preceding weeks, rose again to 15 last week, and included ten in Glasgow and two in Aberdeen. The deaths referred to different forms of "fever," which had been three in each of the three preceding weeks, declined last week to two, both of which were registered in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 107, 88, and 89 in the three preceding weeks, further declined last week to 63, and were 30 below the number in the corresponding period of last year. The causes of 16, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·0, 19·4, and 19·3 per 1000 in the three preceding weeks, declined to 17·2 per 1000 during the week ending June 17th. During the past four weeks the death-rate has averaged 18·7 per 1000, the rates during the same period being 14·1 in London and 16·2 in Edinburgh. The 125 deaths of persons belonging to Dublin registered during the week under notice were 15 fewer than the number in the preceding week and included three which were referred to the principal infectious diseases, against four, eight, and five in the three preceding weeks; of these, two resulted from whooping-cough and one from diphtheria, but not any from small-pox, from measles, from scarlet fever, from "fever," or from diarrhœa. These three deaths were equal to an annual rate of 0·4 per 1000, the death-rates last week from the principal infectious diseases being 1·2 in London and 2·6 in Edinburgh. The two fatal cases of whooping-cough corresponded with the number in the preceding week. The 125 deaths in Dublin last week included 17 of children under one year of age and 27 of persons aged 60 years and upwards; these numbers were respectively five and 24 below those recorded in the preceding week. Five inquest cases and two deaths from violence were registered; and 56, or nearly 45 per cent., of the deaths occurred in public institutions. The causes of three, or more than 2 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: G. Ley to the *Juno* and H. L. Penny to the *Argonaut*, on recommissioning. Surgeons: W. B. Maurice to the *Egmont* for the *Maine*; J. S. Dudding to Haslar to assist in instruction of surgeons on entry; and C. M. Woods to the *Juno*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. G. MacNeece, from Dublin, has been appointed Principal Medical Officer at Malta, with promotion to Colonel. Lieutenant-Colonel H. W. Hubbard takes up temporary duty under the Director-General of the Army Medical Service. Captain E. C. Hayes is appointed member of a medical board for examination of university candidates for commissions in the Regular Army.

VOLUNTEER CORPS.

Rifle: 20th Middlesex (Artists'): Surgeon-Captain H. D. Brook to be Surgeon-Major (dated May 29th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Seaforth and Cameron Bearer Company: John William Mackenzie to be Lieutenant (dated June 17th, 1905).

ROYAL ARMY MEDICAL CORPS EXAMINATION.

An examination of candidates for not less than 40 commissions in the Royal Army Medical Corps will be held on July 27th next and following days. Applications to compete should be made to the Secretary, War Office, 68, Victoria-street, London, S.W., not later than July 17th, on which date the list will be closed. Candidates who are over the regulated limit of age at the date of the examination will be permitted to deduct from their actual age any period of service in the field after Oct. 1st, 1899, that they could reckon towards retired pay and gratuity if such deduction will bring them within the age-limit. The presence of candidates will be required in London from July 25th.

THE JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The June number of this journal is a good one and is well illustrated with plates, diagrams, and tables. Among the original communications and clinical and other notes we may call attention to the article by Lieutenant-Colonel A. M. Davies, R.A.M.C., dealing with the Direct Transmission of Enteric Fever, to the continuation of Researches on Malaria contributed by Major Ronald Ross, C.B., F.R.S., D.Sc., and to the paper On the Further History of Five Cases of Arterio-venous Aneurysm of the Neck, with some Remarks on the Condition Generally and its Treatment, by Mr. G. H. Makins, C.B., F.R.C.S. Eng., surgeon to St. Thomas's Hospital. There are several other papers which are also well worth reading.

VENEREAL DISEASE IN INDIA.

The Army Medical Report for 1903, just issued and dealt with in another column (p. 1740, contains a table showing the admission-rates for all forms of venereal disease per 1000 of strength of European troops serving in India from 1897 to 1903. From this it will be seen that there has been on the whole a large decrease of this class of disease since 1899. Notwithstanding this reduction, however, and despite the efforts of the military and medical authorities, the admission-rate for 1903 was still as high as 249·5 per 1000.

THE WAR IN THE FAR EAST.

There is an absence of any trustworthy news regarding the peace negotiations. There are no signs of any immediate armistice; on the contrary, Marshal Oyama has apparently commenced his final movement against General Linievitch and the greatest battle, as far as stupendous numbers are concerned, remains to be fought. Will it prove to be a final *débâcle* like that of Sedan? As far as can be gauged by what has appeared in the Tokio press public opinion in Japan is, and quite naturally, strongly opposed to any armistice. Nothing will now satisfy Japan short of granting her the full rights of a victor and the placing of peace in the Orient on a durable and permanent basis. The Japanese leave nothing to chance and their success has not simply been the result of their patriotic courage but of the application of science to the art of war, and in no respect, perhaps, has this been more observable than in their medical, sanitary, and hospital arrangements.

PROPOSED NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.—On Wednesday, June 28th, at 4.15 P.M., at the Mansion House the Lord Mayor will preside at a public meeting with the object of forming a league to stimulate public interest in the physical condition of the people throughout the kingdom; to establish close association and centralisation of all societies and individuals trying to combat such influences as tend to produce national physical deterioration; to aid existing organisations; and to start organisations for physical health and well-being wherever none exists. The movement will be on strictly non-political and undenominational lines and the council is formed of representatives of all orders, professions, and institutions throughout the kingdom. Further information can be obtained on application to the interim secretaries, care of Twentieth Century League, 28, Victoria-street, London, S.W.

Correspondence.

"Audi alteram partem"

THE METROPOLITAN HOSPITAL SUNDAY FUND.

To the Editors of THE LANCET.

[illegible] places of worship of the metropolis on behalf of the hospitals and dispensaries for the treatment of the sick poor.

This year the council has 220 institutions seeking to participate in the Fund. The needs of all these charities, if only to reimburse them for last year's outlay on the London poor, would not be covered by £100,000.

Mr. George Herring has again promised to add 5*s.* to every sovereign raised this year in places of worship or in the City up to a total of £100,000. This means that the hospitals can receive up to £125,000 towards the maintenance of their patients (not anything for building). The whole collection last year was £63,000.

There are 10,000 beds in the various London hospitals and 105,000 in-patients occupied them last year.

There is happily no necessity for me to enlarge on the merits of these institutions, but I desire to point out the unique character of this annual collection and the oppor- [illegible] practical sympathy [illegible] [illegible]spective of creed, is offered the privilege to easily gratify his sympathy with the suffering poor. He is not subjected to pressure, and of imposture there can be no fear.

Should any of your readers be absent from public worship, or not in London on Sunday next, they may remit their contributions to me at the Mansion House.

I am, Sirs, yours faithfully,
JOHN POUND, Lord Mayor.
The Mansion House, E.C., June, 21st, 1905.

INFANTILE SPLENIC ANÆMIA.

To the Editors of THE LANCET.

SIRS,—Having read the extremely interesting and carefully investigated case of Infantile Splenic Anæmia, recorded by Dr. S. G. Scott and Dr. W. H. Maxwell Telling in THE LANCET of June 17th, p. 1638, I should like to point out that, as it seems to me, the case belongs to a group which is by no means limited to infants. In fact, there appears to me nothing peculiarly "infantile" in the main features of the case except the fact that the patient was a baby. The case fits in with some of those which have been described in Germany under Leube's heading "leukanæmia" and in France by Vaquez and others as "myeloid splenic anæmia." In this group grave anæmia, with or without a moderate increase in the total number of white cells, is combined with "myeloid" changes in the spleen, &c. In my case of leukanæmia, described in the Transactions of the Pathological Society of London (1904, vol. lv., p. 288), the patient was a man, aged 58 years. There was at one time an absolute leucopenia, yet at the necropsy the enlarged spleen and liver were found loaded with erythroblasts, myelocytes, and large mononuclear cells, the liver in addition containing a considerable number of giant cells. The enlarged hæmolymph glands, besides lymphocytes and erythrocytes, contained erythroblasts and large mononuclear cells similar to those permeating the splenic pulp and likewise a few coarsely granular eosinophile cells and giant cells. In my case the bone marrow had undergone a connective-tissue change which, though probably not an essential feature of such leukanæmia cases, doubtless contributed towards the transformation (reversion) of the spleen and liver into blood-producing organs. On the whole, it seems likely that cases of leukanæmia in adults similar to mine are to be regarded as instances of grave anæmia from any cause in which the [illegible] some of the lymph gland [illegible] which is partly of a co[illegible] Dr. Scott and Dr. Telling it also appears that at least some cases of grave "splenic anæmia" in infants are to be explained in the same way.

I am, Sirs, yours faithfully,
Harley street, W., June 17th, 1905. F. PARKES WEBER.

THE PRINCIPLES OF HEREDITY.

To the Editors of THE LANCET.

SIRS,—It is hardly fitting that I should enter into a discussion concerning the demerits of my own book. But perhaps Mr. M. D. Eder will allow me to trespass a little on his kindness. He states that "a Bolivian garrison on the upper Amazon, to which I had been sent as medical officer, was besieged for six months. The garrison consisted originally of some 350 Bolivians, mainly Indians, and some 40 civilians, North Americans, Italians, Swiss, &c. Beri-beri broke out during the siege, a disease unknown both to the Indians who were from the Bolivian highlands and to the Europeans. Although all were exposed to similar conditions, insufficient food, sleep, &c, over 100 of the Indians died, whilst of the Europeans only one had it (mildly) after having been taken prisoner and severely ill-treated."[1] The remarkable circumstance here is not that the Indians suffered greatly under the very severe conditions but that the Europeans did not. Observers seemed tolerably agreed that in other parts of the world Europeans have no special immunity. For example, to quote Sir Patrick Manson: "*Race.*—This has probably no influence one way or another further than that the superior hygienic conditions of the European in tropical climates imply a less frequent and less intense exposure to the specific cause than is the case with the coloured native. The European enjoys no absolute immunity; under suitable conditions he contracts the disease readily enough."[2]

Assuming that Mr. Eder is not mistaken in his observations it would seem, then, that there is some surprising peculiarity in the waters of the Upper Amazon or the neighbourhood which confers all but absolute immunity on Europeans, even under the most "suitable conditions," though not on the natives. If Mr. Eder could amplify his account so as to elucidate this interesting point he would confer a valuable service on science and humanity.

I am, Sirs, yours faithfully,
Southsea, June 18th, 1905. G. ARCHDALL REID.

To the Editors of THE LANCET.

SIRS,—I have not yet read Dr. Archdall Reid's new book and therefore hold no brief for it, but Mr. M. D. Eder's criticisms seem themselves to require some explanation. For instance, the fact of drunken *individuals* being found among the Jews is supposed to controvert a general principle that the Jews as a *race* are not hereditarily drunken. Surely it is recognised by us all, whether we agree with Dr. Reid or not, that a man may obtain from out of his environment that which has not descended to him from his ancestors. And I think, moreover, that as a fact, and quite apart from any biological significance it may have, it is universally admitted that the Jews as a race *are* exceedingly moderate drinkers.

With regard to malaria, Dr. Reid's critic is not justified in attempting to demolish the law of the establishment of immunities (by continuous elimination of the unfit) by saying that under this law the English should now be malaria proof, because "until quite recently malaria was very prevalent in our island." First of all, malaria was never general in England; it was confined within comparatively narrow limits over what in those days was a very isolated tract of country, inhabited by an exceedingly sparse population. We know, too, that up to comparatively recent times—a century at the outside—it was the habit of the people of the countryside to [illegible] in consequence [illegible] contact with the disease would be strictly limited to an exceedingly narrow section of our population, and that, too, a section which hardly supplies the probable visitors to malarial countries. At any rate, if it does it is quite fair to assume that the few impervious members of the white communities so situated are derived from it and that the susceptible persons are derived from that greater mass of

---

[1] THE LANCET, June 17th, 1905, p. 1675.

[2] System of Medicine, Allbutt, vol. ii., p. [illegible]

Englishmen which has never been exposed to the malarial influence.

Shifting his ground, Mr. Eder says: "There is nothing to suggest that the parasite that once flourished here was different from that now existing in other countries." Then why does he suggest it? As a matter of fact, it is a suggestion well worth our consideration, judging from the analogies presented by proved and established conclusions as to the effects of different environments upon the *causæ causantes* of other parasitic diseases. It is quite conceivable that the malaria parasite in this country was as modified in its relation to the malaria parasite of the West Coast as the red grouse of Scotland is modified from the willow grouse of the continent. I am, Sirs, yours faithfully,

June 19th, 1905. W. GEORGE CRESWELL.

To the Editors of THE LANCET.

SIRS,—I observe that Mr. Eder (in his letter on the above [illegible] in THE LANCET of June 17th, p. 1675) [illegible] principle of natural selection, denies that heredity has any influence in the causation of tuberculosis, and even doubts whether it plays a part in causing insanity. *May I ask his reasons?—I am, Sirs, yours faithfully,*

Wimpole-street, W., June 19th, 1905. HARRY CAMPBELL.

THE CENTRAL MIDWIVES BOARD AND THE BELFAST UNION MATERNITY HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I have read with much interest and appreciation your very just and well-deserved strictures on the action of the Central Midwives Board towards the Belfast Maternity Hospital in refusing to recognise the nurses who have been trained there. Allow me to bring to your notice what seems to me its equally unjust and harsh action in regard to the nurses trained in the Belfast Union Maternity Hospital.

This hospital has been recognised by the Central Midwives Board as a training school for the future as the conditions existing there fulfil all its requirements, but it has refused to enrol any of the nurses trained in this hospital prior to March 31st of this year, except those who were in *bonâ-fide* practice for one year prior to the passing of the Act and (this is what makes it so absurd) who had exactly the same training as those who were refused. The Central Midwives Board has taken this action notwithstanding that it was pointed out to it: (1) that no change has been made in the conditions of training in this hospital for the past ten years, except that formerly the period of training was six months instead of three as required by the Central Midwives Board; (2) that all these nurses before obtaining certificates had to pass the very severe examination of the Ulster Examining Board of Midwifery, a board composed of such eminent men as Professor J. W. Byers, Dr. John Campbell, Dr. Brice Smyth, Dr. Alexander Dempsey, Mr. Andrew McConnell, Mr. Robert Hall, and Dr. J. Lynass, all of them, except the last three, being unconnected with the hospital; (3) that all these nurses prior to beginning their obstetrical course had had two years' medical and surgical training and passed a searching examination in these subjects; and (4) that many of the nurses go each year to England to follow their profession.

It seems to me that no nurses could undergo a more thorough preparation, that this is the class of nurse the Midwives Act was intended to encourage, and that a great injustice has been done by the Central Midwives Board in refusing to place these thoroughly trained and experienced nurses on its roll of certified midwives.

I am, Sirs, yours faithfully,
JOHN MCLIESH, M.B., D.P.H. R.C.P.S. Irel.,
Physician in Charge of Belfast Union Maternity Hospital.
Belfast, June 17th, 1905.

DEATH CERTIFICATION.

To the Editors of THE LANCET.

SIRS,—All who correctly appreciate the national value of accurate and uniform certification of causes of death to public health and sanitary progress must feel grateful to "A Provincial Surgeon" for his timely and useful suggestion, in THE LANCET of June 17th, p. 1677, that every medical student should receive, before completing his curriculum, systematic instruction as to the manner of filling up death certificates and for calling the attention of medical practitioners to the gravity of their responsibilities to the public, imposed upon them by statute, to certify "to the best of their knowledge and belief" the cause of death of each patient attended by them during his or her last illness. There can be do doubt that this responsibility has recently been rendered increasingly onerous, among other causes, by the phenomenal development of industrial insurance, which has to a great extent degenerated into a most dangerous form of gambling. It is an open secret that medical practitioners are now frequently urged by relations or friends of deceased patients to certify the cause of death in such a way as not to endanger the payment of insurance money or even to alter a certificate accurately filled up in order to facilitate the payment of such money. This and other unpleasant and inconvenient consequences of the responsibilities to which "A Provincial Surgeon" calls attention appear to have borne fruit in the deliberate and startling suggestion to eliminate the Cause of Death column from the death register. That such a fatal blow to sanitary progress would ever be sanctioned by statute it seems impossible to believe. It would, however, be well for those who have favoured this suggestion to consider seriously what its effect would be on public health administration.

While fully recognising the value of your correspondent's letter it is impossible to endorse his opinion that the present system of death certification, governed by the Births and Deaths Registration Act, 1874, "would be absolutely perfect" if the medical practitioner, the legal informant of the death, and the registrar were to carry out their respective duties in strict accordance with that Act. It has long been urged and fully admitted by all those interested in public health and in the value of mortality statistics that the Act referred to urgently requires amendment, at any rate, in the following directions: (1) to secure the due certification of the cause of death of any person dying without the attendance during his or her last illness of a registered medical practitioner, if an inquest is not held concerning such death; and (2) to secure the more satisfactory certification and record of all alleged cases of stillbirth. I am, Sirs, yours faithfully,

Surbiton, June 20th, 1905. NOEL A. HUMPHREYS.

MEDICAL CERTIFICATES IN RESPECT OF SCHOOL ATTENDANCE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 27th, p. 1442, you have an annotation with the above title upon the fees offered by the Kent education committee to medical men for supplying certificates of sickness to parents whose children are unable to attend school. I should like to state that I am in entire agreement with the remarks you have made on the subject and to point out that the fee which this division of the British Medical Association proposed as suitable for acceptance by medical men was 2*s*. 6*d*. for examination and certificate at the house of the medical man and 5*s*. if a visit were necessary to the child's home. I am induced to publish our conclusions in the hope that further action by education committees in the future may be met in a similar way in other parts of the kingdom to prevent the evils you have pointed out.

I am, Sirs, yours faithfully,
OSBORNE D. MARRIOTT, M.D. Glasg.
Sevenoaks, June 19th, 1905.

A NEW ELECTRO-CYSTOSCOPE.

To the Editors of THE LANCET.

SIRS,—Under this title Dr. W. K. Otis of New York describes his new cystoscope in THE LANCET of June 10th. He claims that the area visible with his cystoscope is as large as the ring A (diameter 75 millimetres) and with a Nitze-Leiter cystoscope as small as the ring B (diameter 43 millimetres). As far as the instruments made by Leiter are concerned this is a mistake, as the diameter of the area seen is 65 millimetres, while the prism is at a distance of 40 millimetres *from the object.* Dr. Olis's instrument does, therefore, not give a field four times as large, as he claims; it is only 1·3 times as large.

The diameter of the field has been altered twice in the Nitze-Leiter cystoscopes. When they were first brought out

17 years ago it was rather narrow, but a few years afterwards the lenses were altered at the instigation of Mr E Hurry Fenwick and the diameter of the field was for many years quite as large as *that of Dr Otis s instrument*, but it was found that better optical results—i e a more perfect and uniform sharpness over the whole field—could be obtained by reducing the field a little and other lenses were therefore adopted a few years ago Nearly all the European cystoscopes of normal size give now the same size field of 65 millimetres diameter

It seems to me that the Nitze Leiter cystoscope which Dr Otis compared with his new instrument must have been an old pattern The other improvements which he mentions—i e the possibility to inflate the bladder with air, to withdraw the whole optical apparatus to wash out the bladder and cold lamps with central pin contact—have been in use here some years already

I am Sirs yours faithfully

New Cavendish street W K SCHALL

THE ALTERED TREATMENT OF PNEUMONIA DURING THE LAST QUARTER OF A CENTURY

To the Editors of THE LANCET

SIRS—I can confirm Mr H Ivers Kirkpatrick s statement in THE LANCET of June 10th p 1609 as to the good results obtained by blistering in pneumonia For the last 30 years I have invariably applied this form of counter irritation and the longer I live the more convinced I am of its efficacy in most cases (not all) As a country practitioner in my early career I found pneumonia and pleurisy to be the most common of the acute diseases and had many cases through my hands in 14 years These were chiefly of the sthenic or active type, attended by well marked physical signs and often urgent symptoms. When

returning as the first sign towards resolution I can recall more than one case apparently desperate where the consultant held out no hope of recovery but which pulled
and the aid of brandy to keep
sease subsided When I mention
I am generally met with a faint
smile and the remark that ' blistering is not necessary I will however, trust the " bridge that bears me safely over The emp lytta spread on sticking plaster leather or thick brown paper acts better than any liquid vesicant It is longer in its action but more pronounced in its effect of causing absorption of the exudation in the air cells

I am, Sirs yours faithfully

Hospitals and Endowments

ONE rarely looks at a hospital report without finding two
work has increased and is
that funds are wanted so
Two recent cases may be
taken During the present month an appeal from the committee of the Ancoats Hospital for £15 000 appeared in the papers It is an admirable institution, with 114 beds and cots with wards for men women, and children and a convalescent home near Alderley Edge for 26 patients This home was built, through the great generosity of an anonymous friend on land given by the Lewis trustees and also equipped at a cost of £12 000 The convalescent home is found to cost in maintenance about £800 a year The committee ' wish to collect at least £15 000—£10 000 to form an endowment fund for the convalescent home and the remainder to clear off the debt The other case is that of the Children s Hospital The in patient department at Pendlebury can admit 168 patients and is well known to be one of the best in the kingdom but the out-patient department at Gartside street which was built 30 years ago, is ' wholly inadequate to meet the demands on it In order to bring the latter up to the condition necessary to meet these demands and to remedy imperfections at Pendlebury, the public of Greater Manchester is being asked to subscribe £20 000 It is not only right but very desirable to devote a considerable sum to form an endowment fund as the Ancoats Hospital is attempting to do for its convalescent home An endowment fund is also being formed in aid of the Delamere Sanatorium for Consumption which was built by the munificence of Mr W J Crossley A question arises on which there may be differences of opinion but it is one that deserves consideration as to whether a new charity should be established without reasonable endowment A rich man or a generous public builds a hospital and equips it and so far a good work has been done but without more money it is useless Is it quite the best way of doing good to saddle posterity with the maintenance of a charity in the establishment of which they have had no voice? The locality may remain prosperous or otherwise and if bad times come there is the unhappy spectacle of a hospital striving to keep open its doors for the calls on it for aid are then the most numerous and urgent when its resources are steadily diminishing There would always be plenty of outlets for the bounty of the charitably disposed even if the hospitals were in less dire straits financially than most of them seem to be at present

The Manchester Volunteer Medical Corps

For the last week or ten days Manchester and the Lancashire towns generally have been much given up to making holiday The people pour out in their thousands to the various holiday resorts chiefly those at the seaside such as Blackpool and the Isle of Man (to name two only) so that the dwellers therein have had abundant opportunities of hearing their native tongue ' as Lancaster doth speak it The volunteers to their great credit, have been doing work and hard work in North Wales at Bare and on Salisbury Plain But the Manchester Medical Corps is the only one that specially concerns our profession The volunteers generally seem to have received a good deal of praise and it is gratifying to know that the medicals came in for a very fair share of it About 600 of them were paraded on Salisbury Plain on June 15th and were inspected by Colonel May the principal medical officer of the Southern District, who highly commended them for their smartness He saw them go through various exercises They marched past with transport wagons and full equipment and then he expressed his satisfaction
ling that his only regret was
for home service Upon this
who has done so much for the
Manchester Corps asked how many men would volunteer for foreign service in case of need, and the answer came that the whole of them were willing to go We are by other nations and by many in our own land, not esteemed as a
the sense of duty
d on as showing
that with a little encouragement instead of the systematic discouragement which the Volunteers are said to have received for some time past the number of our defenders might be very greatly increased Colonel May also inspected the lines and saw bearer companies at work under the direction of Major J J K Fairclough and the field hospital work carried out under Major Mann In the afternoon the annual sports in connexion with the Royal Army Medical Corps (Volunteers) took place and the prizes were afterwards presented by Colonel Coates

Plague in Manchester

The occurrence of a case of plague in Manchester has startled quiet citizens and the event has been chronicled by newspapers all through the country It is hoped however that the calamity will go no further than it has done already The official statement issued on June 15th did not say whether the sick man had come to his home in Manchester by boat, up the Ship Canal or by train, but simply that the assistant cook on a vessel which arrived at Middlesbrough from Buenos Ayres *via* Hamburg on June 8th was taken ill on June 9th and died on the 12th On the 9th he was so ill that Mr J Tempest of Whalley Range was called in to see him He at once communicated with Dr T C Railton, the medical officer of Withington and Dr J Niven the medical officer of Manchester who on examining the patient agreed with Mr Tempest that the case was one of bubonic plague The patient was at once removed to the Monsall Hospital where he died on the morning of June 12th. The diagnosis was confirmed by Professor S. Delépine and the medical officer at the hospital, and in London by Dr. Klein, acting on behalf of the Local Government Board, who made independent bacteriological examinations. All necessary measures have been taken to prevent the spreading of the disease and there seems to be no reason to fear any further outbreak. It is stated that in consequence of dead rats being discovered on board measures were taken to destroy all rats and to disinfect the ship. Precautions have been taken at Middlesbrough as well as in Manchester to guard against the extension of the disease. The Ship Canal was, of course, suggested to many minds as the route by which the plague would come to Manchester, but the patient, a lad 17 years old, after leaving his ship at Middlesbrough, travelled on the Thursday night by train to Manchester and reached his home on the morning of Friday, June 9th. The house was thoroughly disinfected "and so also were all the persons with whom he had come in contact." There seems no cause, therefore, for any general alarm and there is no evidence that any is felt.

June 20th.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Sanitation in the Rhondda Valleys.

THE Parliamentary Bill promoted by the Rhondda urban district council, which has now passed the House of Commons and which is passing unopposed through the House of Lords, is of special interest because it is not many years since Dr. R. Bruce Low made a very detailed inspection of the district in consequence of a representation addressed to the Local Government Board by the Glamorgan county council to the effect that the Public Health Acts had not been properly enforced in the district. Dr. Bruce Low did not endorse this grave conclusion of the county council but he pointed out a series of insanitary conditions which required to be remedied. Within the last few years much has been done in the direction indicated by the Board's inspector. Extensive sewers have been laid, water carriage is almost universal, a well-equipped isolation hospital has been erected, and a refuse destructor has been installed, and when the provisions of the district council's Bill are in force many difficulties in administration will be swept away. Great difficulty was often experienced in compelling owners of property to pave backyards unless a very distinct nuisance could be proved but the Bill empowers the council to require the paving of these yards to the extent of 150 square feet. The clauses referring to infectious diseases include a prohibition of infected persons carrying on any trade or business in such a manner as to be likely to spread infection, the council having authority to compensate any person affected by this prohibition. The same clauses confer (1) power on the medical officer of health to examine school children and to exclude them from attendance at school, parents and others being liable to a penalty if they send an excluded child to school without the permission of the medical officer of health; (2) power to require from school teachers lists of the names and addresses of children in attendance at school, suitable payment being made; (3) power to require the disinfection of all infected articles; and (4) power to provide nurses for attendance upon any person suffering from an infectious disease in the district. Dairymen who supply milk within the district are required to notify to the medical officer of health all cases of infectious disease among persons engaged in their dairies and they must also report the existence of any case of tuberculosis of the udder among their cattle and they are prohibited from selling for human consumption the milk of any cow suffering from tuberculosis of the udder. A very important provision of the Bill requires a common lodging house and the keeper of such a house to be registered for one year only and enables the council to refuse to re-register at the end of each year either the house or the keeper. Existing registered houses are affected by this clause. An attempt has been made to deal with the vexed question of combined drains by empowering the council in certain circumstances to require two or more houses to be drained by means of one drain but it is specifically stated that this is to be considered a drain and not a sewer. The difficulties attending the enforcement of Section 19 of the Public Health Acts Amendment Act, 1890, are overcome by extending the powers given by that section in relation to two or more houses belonging to different owners so that they shall apply to two or more houses belonging to the same owner.

Typhoid Fever at Bridgend.

There is some evidence of an abatement of the epidemic of typhoid fever at Bridgend. During the first week in June 17 cases occurred, making a total of 46 cases between May 20th and June 10th. The patients are distributed all over the town, about half a dozen being among the well-to-do and the remainder are of the working class. The house drains of the houses concerned are all connected with the sewerage system of the town. The main sewer outfall discharges directly into the sea, but for some time past, during the carrying out of repairs at the outfall, the sewage has been discharged into the river about one and a half miles below the town. In a special report upon the outbreak the medical officer of health (Mr. Wyndham Randall) gives sufficient reasons for excluding the water-supply, milk, or shell-fish as a cause of the epidemic. By a process of exclusion he attributes the outbreak to the exceeding dryness of the early months of the year indirectly leading in some way to the specific pollution of food.

Water-supply of Glamorganshire.

Although the rainfall in many parts of the county of Glamorgan is considerably above the average of the rest of England and Wales there are some districts which are very inadequately supplied with water. There is quite enough water but difficulties are found in securing proper storage grounds especially in the coal-fields. In order to consider what steps should be taken to remedy the conditions indicated a committee of the county council recently decided to confer with the sanitary authorities and to discuss the desirability of forming a water board for the whole county.

Health of Cornwall in 1904.

The annual report of the sanitary committee of the Cornwall County Council, which has just been issued, states that the rural population was 186,376 and the urban population 136,329. During the year 1904 there were 7201 births registered, giving a rate of 22·31 per 1000, against 22·69 for 1903. The total number of deaths registered was 4752, giving a general death-rate of 14·72 per 1000, compared with 14·21 for 1903; the separate death-rates of the rural and urban districts were 14·12 and 15·54 per 1000 respectively. 185 deaths occurred from zymotic diseases (equal to a rate of 0·573, against 0·357 in 1903). 806 deaths were those of children under one year (inclusive of 149 premature births), equal to 111·92 per 1000 births. 428 deaths were due to phthisis and 106 to other forms of tuberculosis, compared with 445 and 106 respectively in the previous year.

Taunton Isolation Hospital.

At the meeting of the Taunton town council held on June 13th considerable discussion took place over the action of the Taunton rural district council in reference to the management of the joint isolation hospital, this action having led to the resignation of Dr. H. J. Alford, the medical officer of that institution. At a previous meeting, as already mentioned in THE LANCET of May 27th, p. 1462, the town council had decided to terminate the dual control of the hospital and Dr. Alford had decided to continue to hold his appointment under the town council. The rural district council, in a letter which was read at the meeting, refuses to consider any question of severing the joint management of the hospital and suggests that the whole subject should be referred to the Local Government Board. The town council eventually decided to ask the Local Government Board to hold an inquiry into the matter.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

"Medicine: the Mother of Many Humbugs."

THIS was the title of a lecture advertised to be delivered in the Queen's Hall, Edinburgh, on June 13th by the Rev. H. E. Cantel, who was described in the posters as "Overseer for the United Kingdom of the Christian Apostolic Church in Zion." This lecture was the fourth of a series delivered in the Queen's Hall, the previous three not having attracted any special attention. The theme of the fourth lecture attracted the attention of the medical students and some hundreds of them were present at the place of meeting. They were quite decorous in their behaviour for some time but when it became known that the lecturer was not to appear they burst into the hall and conducted themselves in that riotous manner which in past times was not uncommon but which has been rare in recent years. They destroyed many of the hall fittings and eventually found themselves in collision with a considerable body of policemen, who finally had to charge them with their batons. Several students were injured and eight were arrested This type of rowdyism is of course strongly to be condemned and, fortunately for the sake of Edinburgh and her medical students, it is now of very rare occurrence

University of Edinburgh · Resignation of Professor Simpson

It has been unofficially known for some time that Dr A R Simpson, professor of midwifery and diseases of women and children, proposed to resign his chair At the meeting of the University Court on June 12th an application was received from Professor Simpson for permission to retire from the chair as at August 31st next Professor Simpson has occupied the chair for over 30 years and notwithstanding the immense changes and advances which have been made, especially in gynæcology, in that time he has kept well abreast even of this department and is recognised by his colleagues as an able, expert, and successful operator It is hoped that if the resignation be permitted there may be important changes in the chair It is universally held that both gynæcology and diseases of children ought now to be separated definitely from obstetrics, and it is hoped that the University may be able to carry through this very important and pressing change. There ought to be no difficulty from the financial side in carrying through the changes indicated, for chairs which carry with them a status in departments of the practice of medicine or surgery do not necessarily require endowments.

Fourth Centenary of the Royal College of Surgeons of Edinburgh.

The preparations for this celebration are being rapidly completed Invitations have been issued for the commemoration ceremony which is to be held in the McEwan Hall on Thursd.
the body of the
who are requeste
Invitations have also been issued for a reception in the Royal College of Surgeons on the evening of the same day, the reception is given by the President and Fellows of the College There is further to be a garden party on the afternoon of July 21st in the grounds of George Heriot's Hospital, the invitations in this case also being sent out in the name of the President and Fellows of the College

Glasgow and District Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis.

The fourth annual general meeting of this branch was recently held in Glasgow. The council reports that during the past year public meetings have been held at various centres with the object of instructing the public and encouraging individual effort to prevent the spread of the disease Signs are not wanting to show that the public, especially in large cities, are becoming educated to the need of abating the practice of spitting. The Bellefield Sanatorium has been in active operation throughout the year and with very satisfactory results Since the sanatorium was opened 50 cases ha
treated and dismissed,
accommodation for 30,
afford, has from the first been found quite inadequate for the very numerous applications received Plans are, however, in course of preparation for the erection of an additional pavilion, together with a laundry and other accommodation Of course, it is not desirable that patients in the advanced stages of the disease should be admitted to the sanatorium, and in order to help this class of patients it has been determined to institute a dispensary where special advice and treatment may be given to patients suffering from pulmonary tuberculosis Until funds can be raised to establish, to equip, and to maintain a separate dispensary negotiations have been entered into with the health committee of the corporation, which, it is expected, will result in temporary arrangements being completed which will enable dispensary treatment to be carried on in the meantime

Reconstruction of the Royal Infirmary, Glasgow

In THE LANCET of June 10th, p. 1616, attention was drawn to the objections to this scheme which are being raised on the one hand as regards the plans of the new building and on the other hand as regards the damage likely to be done to the appearance of the Cathedral Within the last few days there has been published in the *Glasgow Herald* a letter dated Jan 6th, 1903, and written by Dr. James Finlayson, ex President of the Faculty of Physicians and Surgeons, Glasgow, and at that time a member of the board of the Royal Infirmary, to the chairman of the board In that letter Dr Finlayson says "My opinion all along has been entirely opposed to any scheme for the rebuilding of the infirmary on its present limited area, in which the numbers of the patients were to be increased and in which the difficulties could only be dealt with (I don't say overcome) by piling up six storeys of sick people in such a locality That 660 sick persons should be piled up in six flats with a dense population of the living on the one side and of the dead on the other, and with chemical and other works in the near vicinity, is a plan against which, as a physician, I must protest" Dr Finlayson goes on to add that he is entirely in favour of having a central infirmary of limited size on the present site especially for the treatment of accidents He also approves of rebuilding the front or south house as a new surgical house with every modern idea carried out, leaving the north house, which is little more than 40 years old, for medical wards The letter concludes with the remark that "extensions of hospital accommodation should clearly be sought elsewhere"

Defective Hearing among School Children.

At the annual meeting of the friends and supporters of the Glasgow Ear Hospital Dr T Barr pointed out that one third of the patients treated during the year were children under 15 years of age Most of these children were suffering from adenoids which not only produced mouth breathing and ear disease but also in many cases had a dulling effect on the intellectual faculties There was no doubt that the 892 children who had come for treatment formed a very small proportion indeed of the school children who were suffering from these conditions and who were thereby placed under a great disadvantage at school Of 600 children examined by Dr Barr some time ago in connexion with two board schools in Glasgow about 25 per cent were found to be suffering from more or less defective hearing associated in many cases with nasal obstruction. What a serious effect this must have upon the education of a child one can understand when one bears in mind that the organ of hearing is really the organ of education and the chief medium through which children at school receive their mental impressions

Burial Reform in Scotland.

The movement in favour of cremation seems to be gaining ground in Scotland The Scottish Burial Reform and Cremation Society, Limited, reports that 22 cremations were carried out at Maryhill during the year, making 167 since the opening of the crematorium It was pointed out at the general meeting of the society that what occurred was really a decomposition of the body by hot air, and that there was nothing in the process from which the most sensitive mind could recoil. Those who advocate this method of interment are convinced that it only needs a little further enlightenment on the part of the public to make it more popular The small cost is certainly in its favour, 30*s* being charged for cremation, and this includes half a square yard of ground which would contain the ashes of a family From the sanitary point of view the method has everything to commend it, and when the public come to realise this and overcome their prejudice against it no doubt it will be universally adopted It is worthy of note, and as it should be, that at the general meeting of the society the adoption of the report was moved and seconded by medical men.

Montrose Asylum Board

The annual general meeting of the managers of the Montrose Asylum and Infirmary Board was held in Montrose on June 13th Dr J G Havelock, physician superintendent at the asylum, reported that during the year 66 men and 80 women were admitted, bringing the total number of cases under treatment to 833. 85 inmates were discharged and 37 men and 34 women died On May 14th last there were on the register 297 males and 380 females—total 677, showing a decrease of ten during the year. In dealing with the causes of insanity Dr. Havelock, in his report to the managers, says:—

> There is no subject more beset with difficulties than the estimation of the factors which go to produce the complex variety of symptoms and diseases known under the common term of insanity. Two persons were stated to have succumbed to a new disorder, known as "motor mania," a condition said to be induced by the strain of driving mechanically-propelled vehicles on the roads. It is probable that in a large number of cases where the cause of the insanity is attributed to moral and physical agencies the prime factor is a strong hereditary predisposition.

Continuing, Dr. Havelock states that the general health of the patients has been good and that no accident of a serious nature had occurred during the year. At the infirmary the admissions last year totalled 208, a decrease of two; and the number who had received advice and medicine at the infirmary was 1598, a decrease of 129.

Morningfield Hospital, Aberdeen.

The annual meeting of the subscribers was held at the institution on June 7th. The committee of management reported that at the beginning of the year there were in the hospital 77 patients, consisting of 28 adult males, 44 adult females, and 5 children. During the year the committee had under consideration the cases of 35 applicants for admission, of whom 13—namely, 8 adult males, 4 adult females, and 1 child—were admitted. In the course of the same period 8 patients—6 adult males and 2 adult females—died, and 6 patients—5 adult males and 1 adult female—were discharged. The number of patients in the hospital at the close of the year was 76, the average number throughout the year having been 75. During the year the ordinary expenditure on the maintenance and management of the hospital amounted to £2326 10*s.* 6*d.*, while the ordinary income was £1361 15*s.* 4*d.*, leaving a deficiency of £964 15*s.* 2*d.* During the same period legacies were received to the amount of £126 17*s.* 7*d.*, and a special donation of £500 whereby the deficiency was reduced to £337 17*s.* 7*d.* On the other hand, payments were made for additions and alterations to the hospital to the amount of £353 3*s.* 9*d.*, so that during the year the funds of the institution were reduced by a total of £691 1*s.* 4*d.* The average cost of each patient's maintenance during the year was £29 8*s.* 2*d.*, the average daily expenditure per patient having been 1*s.* 7*d.* These figures compared very favourably with those of kindred institutions and the committee was satisfied that the hospital had been maintained and managed with economy. Notwithstanding the economy which had been constantly practised it had been necessary for many years to apply to ordinary expenditure legacies which from their nature ought, in a large measure at least, to have been reserved and added to capital. Even on the assumption that legacies are available for ordinary expenditure, it must be kept in view that they form a very uncertain source of income and one which from various causes had been on the decline. The amount received from legacies last year was £126 17*s.* 7*d.*, as compared with £770 5*s.* 3*d.* in 1903. The ordinary income of the hospital during the year was sufficient for the maintenance of only 47 patients, whereas the average number maintained was 75. In view of the unsatisfactory position of the ordinary income and expenditure, and in order to restore, as far as possible, the large amount of capital expended on the recent additions and alterations to the hospital, the committee issued, towards the close of 1903, a special appeal for increased public support. The appeal, though widely circulated, did not meet with the support that the committee expected; but it was reasonable to hope that those to whom the appeal brought home the urgent need of the hospital for increased support would continue their contributions in the future, and it was the earnest desire of the committee that they would do so. The committee does not suppose that it is the wish of the public that the benefits of the hospital should be reduced, but it cannot be too clearly understood that if the usefulness of the hospital is to be maintained on the existing scale the subscriptions and donations must greatly exceed their present standard.

New Hospital for Peterhead.

On June 17th the foundation stone of the new infectious diseases hospital for the borough of Peterhead was laid with full Masonic honours by Provost Leask. The hospital, which is on the north side of the town, is of the villa type and contains 16 beds, a provision against epidemic disease which the Peterhead community and its worthy provost consider excessive in view of the fact of the freedom enjoyed by Peterhead from epidemic disease.

June 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Dublin.

ON June 17th a meeting of the University of Dublin was held in the theatre of the College buildings for the purpose of considering the adoption of the honorary degrees proposed by the Provost and Senior Fellows. The University Caput consisted of the Vice-Chancellor (the Right Hon. Mr. Justice Madden), the Provost (Dr. A. Traill), and the senior master non-regent (Mr. George Cathcart), who presided. It was officially intimated that the following degrees had been accepted by the Senate:—

[illegible] rs, Principal of Victoria College, Belfast; [illegible] White; Sir Thomas Drew, President of the [illegible] demy; and the Right Hon. Sir Arthur Wilson, B.A., K.C.I.E.

M.D.—Sir Richard Douglas Powell, Bart., K.C.V.O., President of the Royal College of Physicians of London; and Henry Rosborough Swanzy, M.B., Ophthalmic Surgeon to the Victoria Eye and Ear Hospital and Adelaide Hospital, Dublin.

Sc.D.—Edward A. Schafer, Professor of Physiology, University of Edinburgh; and Sydney Young, Professor of Chemistry, Trinity College, Dublin.

Litt.D.—William Graham, M.A., Professor of Jurisprudence and Political Economy, Queen's College, Belfast; and the Hon. Emily Lawless, the well known author of "Hurrish."

Mus.D.—Michele Esposito.

Outbreak of Glanders in Dublin.

In connexion with the recent death of a man infected with the poison of glanders and the leading article in the last issue of THE LANCET showing that the disease was very serious and prevalent in many parts of England, it is unsatisfactory to note that an outbreak of the affection has recently occurred among the horses of a large firm in this city. At a meeting of the public health committee of the corporation, held under the Diseases of Animals Act at the municipal buildings on June 14th, a report of Mr. Watson, M.R.C.V.S., the inspector of the executive committee, was received stating that a serious outbreak of glanders had occurred among the horses of a large city firm. The animals had been tested by hypodermic injections of mallein and in six cases up to the present a positive reaction had resulted. Alderman M'Carthy, J.P., made an order with the authority of the committee that those animals should be slaughtered at once. He stated that, in his opinion, prompt measures should be taken to stamp out the disease which was of such a highly infectious character and was now such a serious menace to the horse owners of the city. The other horses which may have been infected have been removed from their stables to isolated quarters in which they are kept for further observation and re-testing. The stables have been disinfected by the staff of the public health department, all the public drinking troughs in the city have been closed, the county council has been requested to empty those in the county, and, in short, every precaution has been taken to prevent the further spread of the disease.

The Irish Medical Association.

The annual meeting of this association was held in the Victoria Hotel, Killarney, on June 7th, the out-going President, Mr. R. F. Tobin, occupying the chair. The sixty-sixth annual report was submitted and adopted. At the close of 1904 there were 869 members on the roll, being an increase of 35 over the number for the previous year. The accounts closed with a balance of £90 7*s.* 5*d.* but against this sum and the income expected for 1905 liabilities and law costs estimated at £645 must be set. The incoming President, Dr. William MacSweeny of Killarney, delivered his inaugural address, in which he referred specially to the grievances of the dispensary medical officers—their insufficient salary, absence of compulsory superannuation, and want of certainty about annual holiday. He pointed out that their demands were: increase of salary, compulsory superannuation, and compulsory annual holiday. On the motion of Professor R. J. Kinkead (Galway), seconded by Mr. J. J. Curran, the thanks of the association were conveyed to the retiring President, Mr. Tobin. Dr. Macnamara proposed and Professor Kinkead seconded the following motion:—

> That, in the opinion of the meeting, £200 per annum for dispensaries, £120 for workhouse officers, £300 for both, are the lowest salaries that medical men should be asked to work for, but since, owing to the effect of Section 6 of the Local Government Amendment Act, salaries fall on the local rates, members should not be penalised for non-compliance with the Mayo-Enniskillen resolution, pending a settlement of the question.

After some discussion an addition was made that the salary should be satisfactory to the local branch and approved of by the council Mr P Dounellan proposed and Mr J W Olpherts seconded, the following motion which was carried —

> That the council be instructed to formulate a policy that will enable the association to carry to a successful issue measures which may be adopted for the improvement of members

After a discussion in reference to the issue of the Irish Medical Directory it was agreed to discontinue its publication A motion proposed by Dr Samuel Agnew and seconded by Mr Olpherts was carried in favour of the appointment of a deputation to wait on the Chief Secretary and bring before him the more serious grievances of the Poor law medical officers The resolution also requested the council to make representations to the Local Government Board to lay down a satisfactory basis for the formation of scales of graded salaries The extraordinary general meeting for the amendment of the articles of association was postponed to October The annual dinner was held in the evening in the Victoria Hotel Killarney Dr MacSweeny the President, occupying the chair there was a large attendance and a pleasant evening was passed On the next day (Thursday June 8th) there was an excursion to the famous Gap of Dunloe and in the evening Dr E J McWeeney delivered a lecture on Tuberculosis It is doubtful whether this last annual meeting will really advance the cause of the Poor law medical officers of Ireland A mere repetition of their admitted grievances is not enough, what is wanted is really a lead or some kind of 'fighting policy' Beyond the mere resolution in reference to the Medical Directory little else was accomplished except the expression of pious opinions as to the necessity for some strong line of action

The Direct Representative on the General Medical Council

Dr G L J Greene has declined to go forward as a candidate so up to the present all the candidates in the field are Sir W Thomson (Dublin) Dr L Kidd (Enniskillen) and Dr R B Mahon (Ballinrobe)

An Action against a Medical Man

In the King's Bench Division Dublin on June 9th an application was made on behalf of Alfred Ernest Vaughan to have set aside a verdict obtained by the defendant Mr C K Darrell of Bangor co Down at the last assizes (March) of Belfast, a full report of which appeared in the columns of THE LANCET It was an action claiming damages for negligence and it was now sought to have the verdict set aside and a new trial ordered on the ground that it was against evidence and also on the ground of misdirection and non direction on the part of Mr Justice Wright who tried the case After counsel had been heard the Lord Chief Baron Palles delivering the judgment of the court refused the application and decided that the verdict must stand

The Belfast Foreshore Nuisance

A conference has been arranged between the Holywood urban council and the Castlereagh urban council and the Parliamentary agent of the Local Government Board in reference to the proposed provisional order constituting these two authorities and the Belfast corporation a joint board for dealing with the nuisance existing on the Belfast foreshore

Excision of an Arterio-venous Aneurysm in the Axilla

AT a meeting of the Surgical Society held on May 31st M Mignon showed a male patient on whom he had performed this operation The aneurysm which was the sequel of an old wound inflicted with a knife in the cavity of the axilla, resulted from a communication of the axillary artery with a collateral external vein The internal axillary vein was also wounded but arterial blood did not make its way

ombosed for a distance of four
plied two ligatures and in the
collateral external vein and the
of about two and a half centi

metres Recovery followed without complications although the axillary artery had been tied in a part of its course where there are no collateral branches—namely below the inferior scapular in the portion which is commonly said to be dangerous for ligature At the present time all the signs of aneurysm have disappeared but the patient has no radial pulse

Return of Dr Charcot to France

Dr Jean Charcot has had a splendid reception on his arrival in France When the vessel was off Toulon his friends and a deputation from the Geographical Society of Paris went on board in boats sent by the maritime prefect and the travellers on landing were received at the Mairie They had an enthusiastic greeting in Paris at the Lyons railway station where representatives of the Academy of Sciences the Museum of Natural History and the Geographical Society had assembled Dr Charcot was welcomed by Admiral Humann and then by M Bouquet de la Grye and M Perrier in the name of the Institut and of the Museum of Natural History The Minister of Marine afterwards presented Dr Charcot with the insignia of Chevalier of the Legion of Honour at the same time addressing him in complimentary terms The Geographical Society received Dr Charcot and his party at a special meeting held at the Sorbonne on June 16th

Apparatus for Anæsthesia in Operations on the Head, Face, and Mouth

At a meeting of the Surgical Society held on June 7th M Delbet showed an ingenious simple, and practical apparatus for bringing anæsthetic vapours to the laryngeal opening in operations on the face nose and mouth Vapour of chloroform ether or ethyl chloride may be employed The apparatus consists essentially of a flattened hollow plate shaped like a tongue depressor and jointed in several separate portions at one end an arrangement which gives it somewhat the appearance of a lobster's tail This jointed extremity passes over the base of the tongue and resting on the epiglottis forms at the same time a cap over the laryngeal opening and a nozzle for the supply of anæsthetic vapour which is brought through the 'lobster's tail' by india-rubber tubes connected with any of the various kinds of chloroform or ether apparatus For operations on the tongue and on the soft palate which would be difficult if not impossible with this instrument M Delbet has devised a special form which acts on the same principle and can be used easily in such cases

Neglect to Notify Infectious Diseases

At a meeting of the Academy of Medicine held on June 6th M Vaillard complained that non observance of the law with respect to the compulsory notification of infectious diseases was only too frequent and had a bad effect on the health of the army At the present time small pox was rare among soldiers but unfortunately, the same thing could not be said with respect to measles scarlet fever and contagious parotitis the prevalence of which increased from year to year notwithstanding all the prophylactic measures which were adopted Statistics showed that the annual numbers of these cases during each of the last 12 years were 6000 of measles 3513 of scarlet fever and 11 000 of contagious parotitis No similar statistics in other countries approached these figures It seemed to be proved that a soldier very often brought the initial case of an epidemic into barracks after having contracted the disease among the civilian population either in the garrison town or in a place to which he had gone when on furlough Epidemics were therefore most commonly met with at the expiry of the leave given at New Year and Easter Now these initial cases might perhaps be avoided if the military authorities were regularly and accurately informed as to the existence of contagious diseases among the civilian population It would then be possible for the military authorities to declare an infected part of a town to be out of bounds and to refuse the men permission to visit places where eruptive fevers were known to exist The prevention of infectious diseases would be easy if the law as to compulsory notification were observed

Medical Aid for Native Women in Algeria

In order to provide medical aid for native women who are either unable or unwilling in consequence of their special customs to consult male practitioners the Governor of Algeria is making arrangements for giving advice free of charge in the towns of the colony where the Mussulman population is sufficiently numerous The practitioners will be females holding the diploma of Doctor of Medicine The Government will supply them with consulting rooms and the requisite instruments as well as with medicines for the use of necessitous patients They will have an annual salary of

2400 francs rising to 2700 and 3000 francs, and those who have charge of infirmaries for natives will have an additional allowance of 600 francs. The Government of Algeria has made an urgent appeal to all female practitioners who may be disposed to second its views by undertaking this work.

Experiments on the Food of Tuberculous Dogs.

M. C. Richet, M. Lassablière, and M. Lesné communicated a paper on this subject at a meeting of the Biological Society held on June 3rd. M. Richet proved long ago that raw meat gave excellent results as a food for dogs in which tuberculosis had been artificially produced but that cooked meat without any addition was the worst of all kinds of food. Of dogs inoculated intravenously with human tuberculosis all those which were fed on cooked meat died, while those which were fed on raw meat, milk, and *bouillies* survived. All the dogs fed on cooked meat lost their appetite and became thin but with raw meat the case was reversed.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Mikulicz.

Dr. von Mikulicz-Radecki, ordinary professor of surgery and chief surgeon to the University Clinic of Breslau, died in that city on June 14th. An Austrian by birth the deceased received his medical education at the University of Vienna, where he qualified in 1875, and afterwards became an assistant to the celebrated surgeon, Professor Billroth. His first work related to the details of antiseptic methods in surgery, which were modified and simplified by him, and studies on antiseptic and aseptic methods were conducted by him during nearly all his surgical career. He showed that the use of the antiseptic spray during the progress of an operation was unnecessary, he replaced carbolic acid by iodoform, and finally he devised methods of sterilising dressing materials and avoiding the infection of wounds by the hands and the respirations of the surgeon. As an assistant of Professor Billroth Professor Mikulicz, following his master, enlarged the field of abdominal surgery, which was then in an early stage, by a number of new operations. He was also much interested in operations on the joints. He was co-editor of the *Beiträge zur Chirurgie* and *Mittheilungen aus den Grenzgebieten der Chirurgie und Medicin;* and, together with Professor von Bergmann and Professor von Bruns, he edited the "Handbuch der Praktischen Chirurgie." After his assistantship in Vienna he became ordinary professor of surgery at the University of Cracow, where he lived from 1882 to 1887, but afterwards left his native country for Germany and became ordinary professor of surgery at the Universities, first of Königsberg and then of Breslau. Professor Mikulicz, who was only 55 years of age, was generally esteemed by both his patients and his professional brethren, who elected him President of the Breslau Medical Society and a member of the committee of the German Surgical Association.

University of Berlin.

At present there are 6279 students matriculated at the University of Berlin as compared with 6096 last summer and 7774 last winter. In the winter semester there is always in Berlin a far greater number of students than in summer, for, according to German custom, students often change their university and in winter prefer the large towns, whilst smaller ones, especially when situated in a fine country, are more popular in summer. The number of students attending the various faculties are as follows: theology, 248; medicine, 924; philosophy, 3255; and law, 1852. Of the students 4538 are Prussians, whilst 765 come from the other German States. The number of foreigners from Europe is 823, of whom 394 are Russians, 179 are Austrians and Hungarians, 43 are Swiss, and 24 are British; 93 come from America, 42 from Asia, five from Australia, and three from Africa. In addition to the matriculated students 4982 persons are authorised to attend the lectures of the university, this number including the students of the technical, veterinary, and other academies and 365 female students who, according to the by-laws, cannot be duly matriculated.

Sanatoriums for Tuberculous Patients.

The German committee for sanatoriums for tuberculous patients held its annual meeting in Berlin on June 8th, the Secretary of State, Count Posadowsky, being in the chair. The secretary, Dr. Nietner, reported that during last year seven new sanatoriums were opened, whilst seven others are now in construction. The number of beds available for tuberculous patients was 9113. The secretary stated that this number was sufficient so far as persons insured under the workmen's insurance laws were concerned, but that for other classes of the population additional accommodation was needed. The committee will henceforth give attention to the provision of asylums for incurable patients, of dispensaries, and of *Walderholungsstätten*—establishments where patients spend the whole day in the healthful air of forests. These *Walderholungsstätten* have recently been kept open not only in summer but also in winter. Dr. Nietner finally made reference to compulsory notification of tuberculosis and compulsory disinfection by the public authorities. Dr. Mannkopf (Remscheid) described the development of the "dispensaires antituberculeuses" in Germany. Of these there were at the present time 42 in existence, the majority being managed by the workmen's insurance institutions (*Landes-Versicherungs-Anstalten*) and by various municipal authorities. He recommended that the dispensaries should become municipal institutions and that they should be established not only in connexion with the cities but also in the country districts. Dr. Weber of the Imperial Health Office then gave an account of the progress that has been made with the researches carried out on behalf of the office on the relationship existing between human and bovine tuberculosis. He said that the "bacillus tuberculosis humanus" and the "bacillus tuberculosis bovinus" were two different species but that the bacillus bovinus might occasionally be present in the human subject also, though only in children under ten years of age. It had been ascertained that the bacillus bovinus might produce general miliary tuberculosis and that it was present in the lymphatic glands of children. As regards the measures to be taken against the spread of tuberculosis he said that the destruction of the bacillus tuberculosis humanus ought to be aimed at principally but that the bacillus bovinus was also injurious to the human species and therefore must not be neglected. The proceedings concluded with an address delivered by Dr. Kayserling on the subject of tuberculosis.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Care of Imbeciles.

The fifth annual Swiss conference on the care of imbeciles took place at St. Gall on June 5th and 6th, when the President of the association, M. Auer of Schwanden, presented a report on the work which is at present being done. There are now in Switzerland 26 institutions for the care of imbeciles accommodating 1011 children. In 24 towns and large villages there are attached to the State schools special classes in which children of weak intellect receive tuition. In 1897 only 567 children attended these classes, but the number now amounts to 1236. The State makes grants of money to insure that efficient teachers may be placed in charge of these classes and may also themselves receive competent medical and other instruction. Professor Furcher, national councillor, spoke on the legal aspect of the care of the weak-minded and the special provisions made under the new Federal law. Schulrat Dr. Sikknegir of Mannheim described his proposals which are being practically carried out in Mannheim in the State schools. He pleads for a further division in the form of intermediate classes, in which children of exceptionally feeble mental capacity should be placed and should receive special instruction in smaller classes under the best teachers. This system, which is most rational, will be introduced next year in the Zürich town schools.

Zürich Sanatorium for Tuberculosis.

Dr. Staub, medical director of the Zürich Sanatorium for Tuberculosis at Wald, has presented his report on the work of the year 1904. Of 260 patients who made an average stay of 129 days at the sanatorium 41 per cent. were in the first stage, 24 per cent. in the second stage, and 35 per cent. in the third stage of pulmonary tuberculosis; 80 per cent. left the establishment in an improved state of health, 62·7 per cent. being fit for active work again. For the purpose of tracing the after-histories Dr. Staub continues to keep in correspondence with about 600 patients who have been at the sanatorium. Of the patients who were under treatment two years ago, 62 per cent. were still fit for work; of those who were under treatment three, four, and fiv[illegible] numbers fell to 52, 48, and [illegible] instructive to note the rela[illegible] stages of consumption. Of the patients in the first stage, from 79 to 90 per cent. were still at work from three to six years after admission, while of those in the second stage from 38 to 62 per cent. and of those in the third stage only from 6 to 24 per cent. were able to work. From this it appeared that even some almost hopeless cases could be rescued. As there were often 50 cases waiting for admission Dr. Staub was proposing to discharge slight cases which were making satisfactory progress after two months' treatment. The good results of the Bernese Sanatorium in Heiligenschwende encouraged him to take this step in the interest of urgent cases waiting for admission.

Zürich, June 20th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Destruction of Mosquitoes in New Jersey.

OWING to the swamps which abound in parts of New Jersey mosquitoes are present in the summer in countless swarms and are responsible for the malaria which is so prevalent. During the past few years attempts have been made to diminish the number of these pests but owing to the efforts being limited in their scope but little success has attended them. Drainage on a wide scale is the only sure means of abolishing mosquitoes. The Board of Health of Elizabeth, New Jersey, has recently decided to drain the low-lying meadows between that town and Newark. A sum sufficient to do about two-thirds of the necessary work this season has been appropriated, while the Central Railroad of New Jersey will be requested to coöperate to the extent of placing culverts under road bed wherever the ditching plan will render that needful.

Insanity in New York State.

The New York State Charities Aid Association has submitted recently to the State Commission of Lunacy a report which shows that in New York State the total number of insane persons in State hospitals and licensed private asylums on Oct. 1st, 1904, was 26,861, an increase of 927 over the figures for the previous year. Of this whole number 25,019 were in the 14 State hospitals. An important feature of the report is the recommendation that improvement should be made in the methods of deporting insane aliens and that in the case of such persons there should be more coöperation between the State hospitals and the United States immigration authorities. The State Charities Aid Association asserts that it has found that insane aliens deported by the Government have not always reached their homes as promptly as they should have done and on more than one occasion they have not reached their homes at all. When the census was taken it was found that the insane population of Manhattan, containing 2,139,632 people, was 7427, while Long Island, with a population of 1,555,152, had 4168 insane.

Alcoholism and Insanity.

The May number of the *New York Post-Graduate Journal* is wholly devoted to articles from the clinic of Dr. Joseph Collins, professor of nervous diseases in the New York Post-Graduate School. The first article is on the Comparative Anatomy of the Anterior Cerebral Artery and is by Dr. William Leseur. This article is exhaustive and accurate and beautifully illustrated. Perhaps the most interesting article of the series is that by Dr. Collins on the Commoner Varieties of Alcoholic Insanity. He maintains that the intemperate use of alcohol is directly or indirectly the commonest cause of insanity. Indeed, he goes so far as to say that it is nearly the sole cause, and that if the drinking of alcohol were stamped out for a century insanity would undoubtedly shrink 75 per cent. Dr. Collins also points out that it is not so much the amount of alcohol that a person consumes as the idiosyncrasy of the consumer that stands in causal relationship to insanity.

Fear inspired by Cats.

Dr. Weir-Mitchell has written on the above subject in a recent number of *American Medicine.* He states that at least one-fourth of his cases of cat terror in grave forms is a family peculiarity. Five in a family of seven had it. In another case, a maternal grandfather, two great aunts, an uncle, and a sister were all thus troubled, and in other families where one had it, at least one other, brother or sister, was more or less affected. Sex appears to have no marked influence but the extreme symptoms are more frequent in women. Dr. Mitchell concludes that the cat emanations may affect the nervous system through the nasal membrane, although unrecognised as odours. A susceptible person who is told that a cat is near when none is in the room may experience the same unpleasant consequences as when the cat is present. It is perhaps worthy of note that many of the victims of cat fear declare that even strange cats seem to have an unusual desire to be near them, jump on their laps, and follow them.

Milk-supply in New York.

The Governor of New York State has signed a Bill requiring owners or operators of milk stations for the sale of [illegible] rocure licences fro[illegible] The applicant mu[illegible] not participate in [illegible]

June 10th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Directorship of the Pasteur Institute, Kasauli.

Colonel D. Semple, who has just retired from the Royal Army Medical Corps, will remain as director of the Pasteur Institute, Kasauli. His salary has been fixed at Rs. 2000 per mensem. This is very satisfactory as the work of the institute has developed very largely under Colonel Semple's management and a great variety of experimental, as well as instructional, work is being conducted. Madras is provided for with the King Institute and Bombay with the Plague Research Laboratory but Bengal is at present neglected. In this last presidency very little encouragement seems to be given to original workers. There are no men regularly told off for research work and there is no properly equipped laboratory for experimental work. For such a large province and with such an enormous population and for a presidency which prides itself upon attracting the pick of the services this absence of encouragement to original work is hardly creditable.

5000 Deaths a Day from Plague: the Course of the Epidemic.

Over 5000 deaths a day are still recorded as the ravages of plague. There has been a decline in the mortality during the last few weeks and a further decline may be expected. The Punjab returned 25,340 deaths for the week ending May 20th, as compared with 29,385 deaths for the previous seven days; United Provinces, 5132, as against 9220; Bengal, 1069, as against 1660; Rajputana, 2142, as against 3292; Bombay districts, 585, as against 838; Burmah, 58, as against 74; Kashmir, 200, as against 295; Bombay city, 594, as against 679; and Calcutta, 172, as against 324. The decline is general and belongs, therefore, to the life of the outbreak, whatever determines its course. The general recrudescence of plague throughout India, which seems now to occur regularly every spring, follows a very similar course to the annual outbreaks which show themselves in Calcutta and Bombay, and these in their turn are like the less extensive outbursts which occur in the smaller towns, the only difference being that the larger the area or the population affected the less rapid are the rise and fall and the longer is the duration of the outbreak.

June 2nd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Infantile Mortality.

SOME time ago the Government statist for Victoria took except[illegible] statement by your correspondent as to the [illegible] aid that com- excess [illegible] While it may pared [illegible] high to call not be relatively excessive it is [illegible] for inquiry and improvement and the Sydney press has recently taken the matter up. In a leading article in the *Sydney Morning Herald* it was pointed out that between the years 1896–1900, roughly, one out of nine infants under one year of age died. In the period 1881–85 about one in eight died; the total mortality of infants under one year for 23 years was over 80,000 in New South Wales, while the other States show much the same record. The article considered that the figures indicated "a quite unnecessary waste" of child life. The Sydney Women's Progressive Association requested the Premier to give assistance for the establishment of a hospital for infants under two years of age and pressed on his attention the statement that over 4000 babies under one year die annually.—At the thirteenth annual meeting of the friends and supporters of the Infants' Home, Ashfield, Sydney, the report showed that the infantile mortality at the home was only 9 per cent., and Dr. C. K. Mackellar, who presided, and Sir James Graham stated that it was clear that a large amount of really good work had been done in the institution.

Friendly Societies in New South Wales.

The annual session of delegates from the various branches of the Australian Natives Association was held recently in Sydney. The President said that the association had had uphill work to keep its affairs straight during the past 12 months. Alluding to the trouble with the New South Wales branch of the British Medical Association, he regretted that the council of that body had not yet seen fit to recognise the association. He had recently asked the council not to come to a definite conclusion before again conferring with the board of the Natives Association, but was amazed to receive a letter stating that the council would not discuss the matter further. He denied that the association was political except in an educative sense. It did not enter into party politics. In the subsequent discussion it was stated that "it was no use blinking the fact that the A.N.A. could not get on without the concurrence and support of the doctors." Some surprising allegations were also made "that the Sydney Hospital refused to admit an unfortunate woman simply because she had been attended by an A.N.A. doctor," that "a woman who had been attended by a medical officer of the association was turned out of the hospital before she was well," and "when they heard of medical men who were paid by the Government refusing to consult with a brother doctor, even where it was a case of life or death, it was time for a Parliamentary inquiry." The session, however, took no fresh action in the matter.—The twenty-fifth annual session of the Independent Order of Oddfellows was also held recently. The report congratulated the brethren on the progress of the Order. There were seven grand lodges, 350 subordinate lodges, and an aggregate membership of about 35,000 under the jurisdiction of the Grand Lodge of Australasia. The membership in New South Wales was 9409. The total net funds of the Order in New South Wales were £72,449.

The Water-supply of Sydney.

The medical officer to the Sydney water and sewerage board, Dr. E. S. Stokes, has submitted a report on the workmen's camp at the cataract dam for the Sydney water-supply, recommending the removal of the camp and that the board should be vested with full control of the camp both in sanitary and disciplinary matters. The engineer-in-chief concurred in the views of the medical officer. A minute by the president of the board set out that the camp had been improperly and injudiciously pitched on a site which presented a danger to the purity of the water-supply, and the board resolved

> That in the opinion of this board it is desirable to have the workmen's camps at the cataract dam and works removed to a site outside the catchment area.

The Teeth of School Children.

The Dental Association of New South Wales has decided to intrust the arrangements for inspecting the teeth of all the school children in New South Wales to a committee of seven. It is proposed to visit each school once. A lecture on teeth and their care will be given and the children who have defective teeth will be made aware of the fact and be tendered advice. The work of inspection is to be carried out gratuitously, the various members of the association volunteering their services.

May 15th.

Obituary.

FREDERICK JAMES GANT, F.R.C.S. ENG.

Mr. Frederick James Gant, whose death took place on June 6th at his residence, 16, Connaught-square, London, W., had for many years occupied a prominent position among London surgeons and was, moreover, well known as an industrious author, not only of strictly professional treatises but also of works on miscellaneous questions—theological, social, and ethical, some of the latter being of a pronounced controversial nature. Mr. Gant was born in Acton-place, Kingsland-road, London, N.E., in December, 1825. In the "Autobiography" which he published in 1905 he describes himself as "born two months before I was due" and makes frequent reference to the weakness of his constitution in early life. His childhood was passed at Eastbourne, on the south coast, to the great advantage of his health. Losing both his parents while a young man, he became assistant to a pharmaceutical chemist in Shoreditch and afterwards entered as a student of medicine at University College, London. In 1849 he took the diploma of M.R.C.S. Eng. and was admitted a Fellow of the College in 1861. In 1852 he commenced practice as a consulting surgeon at 13, Old Cavendish-street, W., and lectured on physiology at the short-lived Hunterian School of Medicine in Bedford-square, W.C. In 1853, on the discontinuance of the Hunterian School, he migrated to the Royal Free Hospital in Gray's Inn-road, where he did a great deal towards the improvement of the pathological museum and lectured on anatomy and physiology. During the Crimean war—namely, from March, 1855, to the conclusion of peace in the spring of 1856—Mr. Gant held the office of civil surgeon in the military hospitals in the Crimea and at Scutari, rendering services for which he eventually received a medal with a clasp for Sebastopol. The subject of his first book, which was published in 1858 was suggested by a casual visit to the Smithfield Club Cattle Show held in London in December, 1857. It was entitled "The Evil Results of Overfeeding Cattle—a New Inquiry," and showed that fatty degeneration of the heart and other muscles was frequent among the prize animals. He had already published in THE LANCET in 1857 a series of ten papers with the title "What has Pathological Anatomy done for Medicine and Surgery?" and these appeared in book form in 1864 as "Principles of Surgery—Clinical, Medical, and Operative." His "Science and Practice of Surgery," published in 1871, was one of the earliest text-books, if not the earliest, to contain an account of the antiseptic methods in surgery which had been originated by Lord Lister in the Glasgow Royal Infirmary about five years previously. He also wrote "Diseases of the Bladder, Prostate Gland, and Urethra" which reached a fifth edition in 1884; "The Student's Surgery," which appeared in 1890; and a "Guide to the Examinations by the Conjoint Board in England and for Diploma F.R.C.S. England," the seventh edition of which, revised by Mr. Willmott H. Evans, was published in 1899. The Lettsomian lectures on the Excisional Surgery of the Joints for Disease delivered by him before the Medical Society of London were published in THE LANCET of May 13th and June 3rd, 1871. In consequence of his position at the Royal Free Hospital Mr. Gant, although not at first in favour of the movement for the medical education of women, became a teacher of the students belonging to the London School of Medicine for Women who were admitted to the practice of that hospital in 1878. In the end of 1890, when he resigned the position which he then held as senior surgeon of the hospital, the addresses presented to him included a very sympathetic and cordial one from the lady students in attendance at the time. In 1899 Mr. Gant received a serious shock in consequence of the death of his wife whom he had married in 1859 and to whom he was devotedly attached. From this time his health gradually failed and his friends were probably not surprised to read the news of his death.

WILLIAM OGLE, M.A., M.D. CANTAB., F.R.C.P. LOND., J.P.

Dr. William Ogle of Derby, who died there on May 16th after a protracted illness, was one of the most respected members of his profession and had been happy in the enjoyment of a long life devoted to good works. He was born in

January, 1824, at Skirbeck Vicarage, near Boston, in Lincolnshire his father being vicar of the parish He was educated at Rugby School under Dr Arnold and subsequently matriculated at St Catharine's College, Cambridge, of which college he was afterwards elected a Fellow, having become a Master in Arts in [illegible] medicine, first at [illegible] at the Rotunda Hosp[illegible] He came to London and was for five years physician to the Royal Pimlico Provident Dispensary, being also attached to St George's Hospital In 1858 he took the degree of M D at the University of Cambridge and in 1868 was elected a Fellow of the Royal College of Physicians of London In 1860 he removed to Derby as acting physician to the Derbyshire Infirmary, which post he held until his resignation in 1891 when he was appointed honorary consulting physician to the same institution In 1894 he was placed on the commission of the peace for the borough Besides many occasional contributions to medical journals he published a series of papers on "Preventive Medicine In Derby, in addition to his professional and hospital duties to the latter of which he devoted much time and trouble he organised and carefully watched over the well known Nursing and Sanitary Institution of that town, of which he was indeed the founder He was an ardent supporter of the Young Men's Christian Association, interesting himself not only in the Derby branch but in other branches elsewhere, and he never lost an opportunity of pressing upon young men the reality of the spiritual life He was a deeply religious man and was greatly beloved by the many friends who understood his strong, yet simple character In 1860 before going to Derby, he married Miss Margaret Lambert of Bradford who survives him His two sons are the Rev Hugh Lambert Ogle, vicar of Plumstead Kent and the Rev Philip Douglas Ogle of Nottingham The funeral took place at the old cemetery, Derby, on May 19th

JOHN MATTHEWS, M D EDIN, L R C S EDIN, L S A

BY the death on June 4th of Dr John Matthews Tyneside has lost one of the oldest members of the profession for he was in his eighty fourth year Although one of the oldest residents of Tynemouth he was a native of Gloucester and went to Tynemouth 47 years ago He took his M D degree at Edinburgh in 1853 He was a man very well known and respected On the foundation of the Tynemouth Volunteer Life Brigade he was made honorary surgeon and he was also medical officer to the Tynemouth pier works Dr Matthews was thrice married and leaves a widow In 1877 he retired from practice and being a keen sportsman he spent much of his time in fishing and shooting, as well as being occupied with his hobbies of wood and ivory turning He was a benevolent gentleman and will be missed by many of the poor of Tynemouth

Medical News.

UNIVERSITY OF CAMBRIDGE—At the examinations for medical and surgical degrees, Easter term the following candidates were successful —

UNIVERSITY OF OXFORD—The degree of D M has been conferred upon William Osler, Hon D Sc, Regius Professor of Medicine, by a Decree of Convocation —The degree of D Sc *honoris causa* has been conferred upon [illegible]

Ray Lankester, M.A., F.R.S., Honorary Fellow of Exeter College, Director of the Natural History Departments of the British Museum.—The following appointments of examiners have been confirmed :—In human anatomy: Robert Howden, B.M. Edin., M.A. Durh. In pathology: James Ritchie, M.A., B.Sc., Fellow of New College. In surgery: D'Arcy Power, B.M., Exeter College.

THE annual Bolingbroke lecture in connexion with the South-West London Medical Society was delivered on June 14th by Sir R. Douglas Powell, Bart., who took for *his subject Some Clinical Lessons from the History of* Medicine in the Last Half Century.

THE QUEEN'S JUBILEE HOSPITAL.—A ball was given at the Wharncliffe Rooms, Hotel Great Central, on June 20th, in aid of the Queen's Jubilee Hospital, Earl's-court, which is greatly in need of funds. Nearly 500 people were present and dancing took place in rooms beautifully decorated with palms and flowers. By kind permission the band of the Scots Guards was in attendance.

NATIONAL FIRE BRIGADES UNION: ANNUAL COMPETITIONS.—The entries for the National Fire Brigades Union Competitions which will open at the Crystal Palace next Monday, June 26th, and which will be continued daily throughout the week, greatly exceed those of last year. The men, nearly 2000 in all, will be housed in tents pitched in the Cedars Grove and will be in charge of Lieutenant-Colonel Dixon and chief officers G. W. Johnson and J. Clulee. On Thursday there will be a special display and an inspection by the Duke of Marlborough. About 600 brigades and 12,000 men are attached to the union which protects a population of over 9,000,000.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The festival dinner of the National Hospital for the Relief and Cure of the Paralysed and Epileptic was held at the Whitehall Rooms of the Hôtel Métropole, London, on June 15th, when Lord Strathcona and Mount Royal occupied the chair. Amongst those present were Sir Felix Semon and Lady Semon, Mr. J. Danvers Power, Dr. T. Buzzard, Dr. J. S. Risien Russell, Dr. F. E. Batten, Dr. E. F. Buzzard, Dr. H. H. Tooth, Dr. W. W. H. Tate, Mr. A. E. Cumberbatch, Dr. C. E. Beevor, Mr. R. M. Gunn, Dr. J. A. Ormerod, Mr. C. A. Ballance, Dr. W. A. Turner, Dr. J. Taylor, Dr. D. Ferrier, and Mr. F. Macmillan (chairman of the board of management). The loyal toasts having been drunk with the greatest enthusiasm the chairman rose and submitted "Success to the National Hospital for the Relief and Cure of the Paralysed and Epileptic." In tracing the history of the hospital from 1859, when it was founded, the chairman explained that the institution was called the "Albany Memorial" at the express desire of Queen Victoria and it was mainly owing to the efforts of the late Duke of Albany that the hospital was re-constructed in 1885. Besides having a country convalescent branch the hospital provided pensions up to about £20 a year for 90 incurable patients. The name and the fame of the hospital had gone abroad throughout the civilised world and patients were sent to it for relief from all parts of the empire and from many foreign countries. The number of in-patients was 1113 and the out-patients numbered 6574. The expenditure was £5041 in excess of the income and money was required to extend the hospital, so that funds were urgently needed. The chairman also mentioned that the institution was greatly indebted to its eminent medical staff who devoted so much time to the good work without fee or hope of reward. Mr. F. Macmillan, in responding to the toast, also paid a high compliment to the medical staff. Mr. Danvers Power then proposed the toast of "The Medical and Surgical Staff." He made a few remarks concerning the differences which existed some time ago between the board of management and the medical staff but had nothing but praise and commendation of the highest order for the way in which the board of management was helped by the medical staff at the present time. Mr. Danvers Power concluded by regretting the absence of Sir John Paget who was to have proposed the toast. Dr. J. A. Ormerod, in replying to the toast, congratulated all concerned on the efficient manner in which the institution was conducted. Mr. A. Royle (one of the board of management) here interposed a toast which was not on the toast list; it was that of "The Ladies" and he called upon Sir Felix Semon to answer on their behalf. That gentleman rose at once and in a brief but witty speech fully discharged the duty which had been thus suddenly intrusted to him. He made use of the opportunity to express the thanks of the staff to all those ladies who had come forward at a time of difficulty and stress to help the hospital and those connected with it. The secretary, Mr. G. H. Hamilton, then announced that the subscription list amounted to over £3000 and he was followed by the Dean of Canterbury who, in felicitous terms, proposed "The Health of the Chairman." He remarked that Professor Ray Lankester had lately lectured on the passage in Genesis in which men were told to replenish the earth and subdue it and have dominion, but he (the Dean) would like to add that it appeared to him that the medical profession sought to subdue nature for the benefit of man. The chairman having suitably responded the proceedings came to an end.

ST. LUKE'S HOUSE, A HOME FOR THE DYING POOR (14, Pembridge-square, Bayswater, London, W.).—The twelfth annual report of this institution, of which Her Majesty Queen Alexandra is the patroness, shows a record of good work for the year 1904. During the year under notice 237 applications for admission were received and from among them 96 patients were selected, 49 being men and 47 women. As there were already 24 patients in the home on Jan. 1st, 1904, the total number of cases dealt with was 120. Tuberculosis and cancer are the principal classes of disease from which the patients suffer. The home is greatly in need of financial help which ought to be forthcoming immediately, for as the report of the medical superintendent points out "it is an excellent thing that we are able to remove from among crowded families all these cases of consumption who, by carelessness as to the disposal and disinfection of expectoration, would become sources of disease to others; all these cases of cancer, also, many of which, unless most skilfully and carefully nursed and tended, become scarcely bearable and very insanitary to those dwelling with them." The healthy of all classes are thus benefited by the compassion shown to the sick, and all classes who are able to do *so should support the institution.*

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, JUNE 20TH.

The Medical Register.

Mr. WEIR asked the Secretary of State for the Home Department whether, having regard to the fact that during recent years 20 names had been struck off the Medical Register by the General Medical Council for infamous conduct in a professional respect and 12 restored, whilst out of six names removed from the Dentists Register for a similar cause one had been restored, he would state if any of those whose names had been restored were originally charged with adultery, and how many.—Mr. AKERS-DOUGLAS replied: The answer is none.—Mr. WEIR: May I ask whether the right honourable gentleman obtained his information from the General Medical Council, for I have some cases I shall be prepared to lay before him.—Mr. AKERS-DOUGLAS: I shall be very glad if the honourable gentleman will give me any information he may have, but I have given him all that I possess.

Human Deaths from Glanders.

Mr. CHANNING asked the President of the Local Government Board whether he was aware that inquests recently held on a stableman in the Star Omnibus Company's stables and on Elizabeth Cousins, the wife of a carman, in Pimlico, and a large number of fatal cases in London hospitals in the past two years had shown the increasing risk of glanders being communicated to human beings; and whether he would, in consultation with the Board of Agriculture, take steps by legislation or by administrative orders to deal with this danger.—Mr. GERALD BALFOUR answered: I have seen reports of the inquests referred to, but I am not aware that there has been any large number of fatal cases of glanders in London hospitals in the last two years. The number of human deaths in London from this cause appears to have been four in 1903 and two in 1904. I am advised that the risk of the disease being communicated from horses to man is not great and that it does not seem to be increasing. But I think it may be desirable that when an inspector of the local authority, under the Diseases of Animals Acts, receives notice of the occurrence of a case of glanders in a horse he should forthwith give information of the receipt of the notice to the medical officer of the district in which the horse is, or was, and I will communicate with my right honourable friend the President of the Board of Agriculture and Fisheries on the subject.

Plague Regulations in Ireland.

Mr. JOSEPH NOLAN asked the Chief Secretary for Ireland whether he was aware that the Local Government Board issued certain temporary regulations respecting plague to the Louth district council, Drogheda union, commencing Oct. 1st, 1900, and that Mr. W. J. O'Keeffe, who was employed to carry out these orders, furnished an account for £21 for performing the duties connected with the same; and whether, seeing that the Local Government Board declined to sanction the payment of this amount, and that Mr. O'Keeffe took legal proceedings for recovery and obtained a decree with costs, the Local Government Board would now make an order apportioning the respective amounts to be paid under this decree by each of the sanitary authorities affected—viz., Ardee No. 1 Rural District Council, Louth (Drogheda union) Rural District Council, Meath (Drogheda union) Rural District Council, and Drogheda Urban District Council.—Mr. LONG said: The temporary regulations referred to were revoked on Nov. 12th, 1900. Mr. O'Ke [illegible] Feb. 1 [illegible] made [illegible] force, [illegible] home [illegible] date and were co [illegible] which time he m [illegible] in respect of w [illegible] apportion the co [illegible] Drogheda. The [illegible] tion of the six [illegible] force. The Louth [illegible] respect of charges for which there was no legal warranty and it now seeks to have the amount of the decree, given through its default, apportioned on the other sanitary districts abutting on the Port of Drogheda, but in the circumstances there is no power to make such apportionment

Notes, Short Comments, and Answers to Correspondents.

THE PLAINT OF THE DYSPEPTIC.

A CORRESPONDENT has sent us the following verses, addressed to the medical profession, of which he is himself a member, and complaining bitterly of the way in which he is treated by a nymph whom in the opening stanzas he describes as

A contrairy
Fickle Fairy,
Known to the world as Little Mary.

We do not know how he can reconcile it to his artistic conscience as a member of a learned profession to have committed the terminal rhyme, but he sins in good company, for Byron and the author of the Ingoldsby Legends have perpetrated similar atrocities :—

Ah! in those happy days of yore
Of unrestricted meals galore,
I could without disturbing slumber
Have simply feasted on cucumber!
  Nor passed the course
  With lobster sauce
  For fear of subsequent remorse!
But now—it is not hid from me
She even grumbles at my Tea!

And worse! for this is past all joking,
She threatens to prohibit *smoking*!
Though I have struggled to explain
It does not enter her domain;
  So now I sigh
  For days gone by,
  And swell the universal cry—
"Can none of you concoct me some muck
To pacify my wretched stomach."

WHAT BECOMES OF BOYS WHO OUTGROW THEIR WORK?

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me whether there has been any inquiry showing what becomes of messenger boys, boys employed in the newspaper trade, and such like employments when past the age for such work. If, as seems probable, the majority swell the ranks of the unemployed we have here at least one cause for deterioration of the race which ought to be carefully inquired into.

I am, Sirs, yours faithfully,
June 20th, 1905. *Δίκαιος.*

TO DEADEN SOUND.

To the Editors of THE LANCET.

SIRS,—I think if your correspondent "J. S. R." were to try some little rubber ear plugs filled with sawdust which were made for me some years ago by Messrs. Lynch and Co., 15, Silver-street, London, E.C., they might help his patient. They are made in several sizes and must fit the meatus. I have prescribed them at various times as a protection against loud sounds, such as firing, and they certainly have a decidedly deadening effect. Probably one, in the exposed ear only, would be necessary during sleep. I am, Sirs, yours faithfully.
June 13th, 1905. E. CRESSWELL BABER.

"HANSEN'S JUNKET TABLETS."

IN our analytical notice last week of this preparation we wrote under the impression that the junket tablets were the product of the Carlsberg laboratory at Copenhagen of which Dr. Emil Chr. Hansen is chief. As a matter of fact they are prepared at the laboratory of Mr. Chr. Hansen, who is a distinguished chemist and well known in connexion with practical investigations on dairy products, milk ferments, and the production, in particular, of an effective rennet which was the subject of our satisfactory analysis.

"THE SAFE SURGICAL SPONGE."

THIS article is the invention of Mrs. George of Oxford, a nurse. The "sponges" are made of highly absorbent cotton stained with methylene purple and hand-knitted so as to present a reticulated surface, thus insuring the greatest possible amount of absorption, whilst from the nature of the material perfect sterilisation is possible. The sponges may be used over and over again with due regard to asepsis, thus rendering them economical, a point that cannot be overlooked since aseptic surgery has so much increased the cost of the toilet of operations. The sponges, though generally useful for all operations of surgery, will be found especially so in abdominal operations, their distinctive colour and appearance rendering it a practical impossibility for them to be overlooked in the body. Whereas other sponges may become stained to the colour of the blood itself and thus only with difficulty be distinguishable, it is a peculiar characteristic of the dye in this case that it turns to a deeper purple when saturated with blood and always stands out in clear contrast to the tissues. The sponges are manufactured by Messrs. Down Brothers, Limited, 21, St. Tho
street, London, S.E.

OLD BOOKS.

To the Editors of THE LANCET.

SIRS,—Is anyone likely to buy an old book, date 1633, print
John Legatt for John Partridge, London, entitled "The Strang
Dangerous Voyage of Capt. Thomas James"? I want to sell it
patient (a widow) who is very badly off.

I am, Sirs, yours faithfully,
June 20th, 1905. P

To the Editors of THE LANCET

SIRS,—Can any of your readers inform me how it is possible
rid of old medical and other books in order to find room fo
editions? One would gladly benefit some medical charity in thi
from time to time, however small the sum realised.

I am, Sirs, yours faithfull
June 17th, 1905. R

◆

Væ Victis.—There is no customary method, and trouble has befor
arisen because of this absence of precedent. It is very hard upo
principal to find himself under engagement to an assistant wh
not discharge his duties; it is very hard on an assistant to b
charged upon the briefest possible notice because he is ill. If po
an arrangement should be come to by which all the hardship do
fall upon one of the parties. In our opinion the possibility
breakdown in health on the part of the assistant, when engaged
prolonged term, ought to be taken into consideration in the
ment.

Belgaum.—We are perfectly certain that the experiments said t
taken place in Paris are pure invention. No such experiments
be performed in Great Britain and if they were performed they
prove nothing. The antivivisection party deals considerably
quotation from speeches by medical men "delivered quite rece
but it will be observed that trifles like initials and dates are u
omitted.

Layman.—The subject is one upon which we should have no obj
to publishing the views of persons not in the medical professio
our correspondent is entirely at sea. The toxins upon whi
depends for his explanation have no existence.

J. G. C.—From what our correspondent tells us we think tha
addition of the basement would be most desirable.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnieres, Paris.
